In Florida, there is a Junior Baseball League where birth certificates have been required in connection with the eligibility of certain players. Bringing up the subject of a baseball league may sound rather light or trivial but is of vast importance when its effect on the registration system is considered. The organization to which reference has just been made first attempted to prove eligibility of players through affidavits of parents made to the manager or official of the league. So many false affidavits were presented that the association finally decided to require certified copies of birth certificates from the State Board of Health. In one particular case, a birth certificate which was filed, sworn to and signed by two American citizens, was branded as a fraud by the league officials as they claimed to have proof that the young man in question had had his certificate dated one year later than his actual birth date in order that he might play that year with the team. It is not necessary to cite other cases, as those in charge of registration are familiar with the many irregularities.

The problem under discussion is not a new one by any means and, due to the fact that the number of certificates coming under the head of "deferred" is small as compared to the number of regular certificates, it appears to have been kept in the background. The custodian of the records in many instances promulgates rulings or laws to meet circumstances as they come to his attention.

Some individuals feel that if a birth certificate is not filed at the time of birth, it is just a misfortune of the applicant. However, to some of us, this seems rather heartless and severe. Very often, unusual circumstances may account for the failure to file a birth certificate at the time of birth. In one case, which came to the writer's attention recently, the attending physician had a severe attack of appendicitis and died a day or two after delivering the baby; in another case, the doctor intentionally neglected to file a birth certificate because he did not receive his fee for medical services. In such instances, should the child in later years be denied a record giving him his birthrights in the United States?

A questionnaire was sent out recently in an effort to learn the procedures now in effect in the various states for filing of deferred certificates. The information compiled from these questionnaires is very interesting. A reply was received from every state. Of these 48 states, only 20 have laws specifying certain requirements for the filing of deferred certificates. Twenty-eight states have rules or regulations but no statutes. One state in the latter group refuses to file certificates for births prior to 1906, and another will not accept a birth certificate for a person born before 1914.

A further study of these questionnaires reveals that the procedures in establishing the date of birth after a lapse of years are not uniform and that the records under discussion will be safeguarded to a much greater extent if the knowledge and experience gleaned from all states is incorporated into a model section of law. In most states, it is found that rules and regulations promulgated by a state board of health are not binding in some courts, if more authority is taken than was specifically stated in the statute. Therefore, it appears to be inadequate for a

state board of health to pass a rule or regulation on a matter as important as the one under discussion.

For the benefit of those states which have no law governing the filing of deferred certificates and for those states where the custodians may feel that their law is not sufficient, it would seem appropriate for this Section to formulate a model law governing the filing of deferred certificates which would include the experiences of every state and safeguard the records against every irregularity so far discovered.

It is as bad, if not worse, to file a deferred certificate which does not state the true facts as not to file a certificate at all. Therefore, the law governing the procedures should be of such construction as to bring out the true facts before a permanent record is made. The experiences and laws of all of the states might be crystallized into a model statute providing for the filing of deferred certificates by incorporating the following provisions:

1. An application form which is quite comprehensive should be filed by the applicant, this form to embrace every item included in a standard birth certificate. In addition, this form should provide for the name of the person who is to sign the affidavit; the relation of the applicant to the child; the history of other brothers or sisters, giving their names, dates of birth, and places of birth. The more comprehensive the application, the more accurately the birth certificate may be prepared. For instance, if the applicant gives as his date of birth one which conflicts with the date of birth of a brother or sister, the error can immediately be discovered. The application should be carefully prepared and, if necessary, returned to the applicant until every questionable detail has been adjusted, such as the ages of the father and mother which should be given as of the date of birth of the child, etc.

2. The birth certificate then should be prepared for signatures by the state bureau of vital statistics where the most experience in this class of work is available.

3. The birth certificate and affidavit having been completed should then be given to the applicant for the signature of the indi-

vidual who is to sign the affidavit attached to or incorporated in the certificate.

4. If the individual who is to swear to the fact and date of birth resides in the United States, the affidavit should be executed before the highest officer in the court of records or his duly authorized deputy; such officer or deputy being instructed to take whatever testimony is necessary to satisfy him that the individual appearing before him knows the facts before affixing his signature or taking oath.

5. In cases where the signer resides outside of the United States, the affidavit supporting the certificate should be executed by the United States Consul.

6. The applicant should then return the certificate, supported by the affidavit described, to the state bureau of vital statistics, where the file date and signature of the state registrar or director are affixed.

The court of records in each division of a state is undoubtedly the most reliable place for the execution of affidavits of this nature and the taking of any necessary additional testimony. Notaries public, justices of the peace, and other like officers, being more numerous, constitute a greater risk.

In Florida, it has been proved definitely that notaries public in certain specific instances have been deplorably at fault. In one instance, the affiant whose name was signed to the affidavit was a thousand miles away from the county and state where the notary public executed the affidavit and affixed his seal. We had previous information that the affiant lived in the middle west. Upon questioning, the notary public admitted having signed the name of the affiant and further, that the affiant knew nothing whatever of his name having been used in connection with the case. Another outstanding case was one in which a notary public complained that the American Consul of a foreign country had defaced or nullified a certified copy of a birth certificate issued by the State Board of Health. This notary public had been instrumental in placing on file the original certificate which was needed by

an individual who wished to gain admittance into the United States. The American Consul General reported his findings to the Secretary of State, Washington, D. C., to whom the matter had been referred, as follows:

The complaints primarily concern the alleged mutilation or nullification of the birth certificates offered by _____ and _____ in support of their applications for passports as American citizens, which applications were refused by the Department. . . . It appears that the Vice Consul, in view of the testimony, endorsed the certificates in such a way as would prevent their use for the purpose of obtaining American passports in any other American Consulate. While this endorsement nullified their use for passport purposes, their legal value in the United States was not lessened. It may be stated that the births of these two individuals were apparently registered over twenty years after the alleged births of the two applicants. . . . The result of this office's investigation, confirmed by the judgment of the Department, led to the refusal of passports and to the conclusion that birth certificates, when the births were recorded years after the event by persons interested in securing the admission of relatives into the United States, could only be regarded as presumptive evidence of American births. It is logical to suppose that the Board of Health of Florida, not having these two men before it personally, relied upon the sworn statement of their sister.

Without in any way wishing to cast doubt upon the authenticity of any certificates issued by the Board of Health of Florida, it is submitted that this office, having had the two men before it in person and having examined them, was in a better position to form an opinion regarding their alleged American births than was the Board of Health.

A representative from Washington who handled this case stated that he had 6 Secret Service officers under his direction who made investigations whenever there was any question of the authenticity of birth certificates presented. He added that birth certificates, not only from Florida but also from other states, were turned down from time to time. Verbally, this official stated that there is a "racket" in a certain district involving notaries public, midwives, and a group of people who sign birth certificates for individuals who were not born in the United States.

In preparing a model statute governing the filing of deferred certificates, it is, therefore, of paramount importance that provision be made for thorough investigation as well as sufficient testimony to be taken by a court officer before a certificate is filed.

Milk-Borne Disease in Massachusetts 1930-1932*

GEORGE H. BIGELOW, M.D., F.A.P.H.A., AND
ROY F. FEEMSTER, M.D., DR.P.H.

*Commissioner, Massachusetts Department of Public Health; and
Assistant Director, Division of Communicable Diseases, Boston, Mass.*

PREVIOUS chronological reports of milk-borne disease in Massachusetts have been published covering varying periods, the last¹ in 1930. During the past 3 years there has been considerable improvement in the regulations regarding the safeguarding of milk and a diminution in the number of cases of disease traced to milk, and, what is perhaps even more significant, a decrease in the number of cases per outbreak, demonstrating that the larger

CHANGES IN CONSUMPTION AND CONTROL

In order to learn the changes which have occurred in the consumption and the sanitary control of milk, questionnaires were sent to 122 Massachusetts cities and towns of over 5,000, which represent over 90 per cent of the population of the state. Replies were received from 100 communities, 10 of which did not give sufficient information to be included in the tabulations.

TABLE I

| Total | | | | 0.45 | 0.44 |

* This figure is obtained by dividing the number of quarts of milk sold daily by the total population of the group.

† Questionnaires were not sent to this group until 1928.

not published in 1919 and Group V was not added until 1929. The figures for 1923 and 1926 were based on only half as many communities as those for 1928 and 1931.

The per cent of milk consumed which is pasteurized is shown in Table III. There has been an increase in all groups except Group IV, so that at present 90 per cent of the milk in the cities surveyed is protected in this way.

Since only 90 of the 355 communities in the state are included in the above tabulations, an attempt is made in Table IV to estimate how much of the total milk consumed daily in Massachusetts is pasteurized. Based upon the assumptions that those cities not reporting in groups III, IV, and V had the same per capita consumption and the same per cent of milk pasteurized as those that did report,

totals for the groups are estimated. Assuming that the towns under 5,000 had a per capita consumption equal to the average of all those answering the questionnaire and that none of the milk in these towns is pasteurized, the amounts sold in Group VI are estimated. In this way it is shown that approximately 80 per cent of the milk of the state is pasteurized. This is a conservative figure and we believe that 85 per cent would be nearer the fact, since it is known that considerable quantities of milk consumed in towns under 5,000 population are pasteurized.

These figures showing that the amount of milk protected by pasteurization has increased are corroborated by the fact that many communities have recently adopted a regulation requiring that all milk sold be pasteurized or from tuberculosis-free herds. Table

TABLE IV.
PER CENT OF TOTAL MILK OF STATE PASTEURIZED
(An Estimate)
(1931)

| <i>Group</i> | <i>Quarts Sold</i> | <i>Quarts Pasteurized</i> |
|-----------------------------|--------------------|---------------------------|
| 50,000 and over (I) | 1,030,933 | 990,536 |
| 25,000-50,000 (II) | 201,943 | 180,651 |
| 15,000-25,000 (III) | 222,810 * | 178,154 † |
| 10,000-15,000 (IV) | 96,332 | 57,657 |
| 5,000-10,000 (V) | 137,450 | 73,920 |
| Under 5,000 (VI) | 174,000 ‡ | |
| Total | 1,863,468 | 1,480,918 |
| Per cent Pasteurized | 79.5 | |

* Estimated on the assumption that the cities in the group not reporting had the same per capita consumption as in those reporting (see Table II).

† Estimated by applying the per cent of milk pasteurized for the group (see Table III) to the estimated total consumption.

‡ All towns under 5,000 included in this group. Quarts sold estimated by using the per capita consumption (0.44) of groups I-V inclusive (see Table II).

V shows that the number of cities and towns now having this requirement compose 84.5 per cent of the total population of the state. As may be noted in Table VI the communities which have recently adopted this regulation are not limited to any one population group, but there has been a tightening up in the regulations controlling milk in all of the groups since 1929. It is encouraging to know that the per cent of those so protected in

towns under 1,000 population has almost quadrupled in the last 3 years, and that the per cent in the remainder of the towns under 5,000 has almost doubled.

In 12 communities practically all milk is pasteurized since regulations are in force which require all milk to be pasteurized or certified and the amount of certified milk is not large. Moreover, large quantities of milk are being pasteurized in communities where regulations requiring it have not been

* Twelve of these communities require milk to be pasteurized or certified; several require all milk to be from tuberculosis-free cattle whether raw or pasteurized.

passed, due to popular demand for protected milk. At the same time dealers are beginning to adopt pasteurization before required to do so because they are finding it the best kind of insurance against financial loss due to the inevitable occasional outbreak of milk-borne disease which continually menaces the dealer who sells raw milk.

That these regulations are being enforced seems to be indicated by the fact that bacteriological examinations of milk have increased even in the face of curtailed budgets, so that there is now an average of 6.6 examinations per 100,000 quarts of milk sold in comparison to 5.4 in 1928, and 4.9 in 1926. An increase of 22 per cent in bacteriological control during the present times seems remarkable indeed.

This increase is not simply more examinations performed by communities already making them; but new communities have added this protection, as shown in Table VII. It will be noted that towns under 10,000 show a good increase in such examinations.

The consumption of certified milk appears to have decreased. In the 1930 report it was estimated that 1.0 per cent of the total milk sold was certified compared to 0.6 per cent in 1927. The

amount has now dropped back to 0.62 per cent. It is not surprising, of course, that such a thing has happened in view of its higher cost and the fact that "rawness" of milk is lessening in its sales value.

OUTBREAKS TRACED TO MILK

The number of outbreaks of disease traced to milk has been remarkably small during the past 3 years: 5 of septic sore throat, 3 of typhoid fever, including 2 in which there was only 1 case each, 1 of scarlet fever, and none of diphtheria. The essential facts in regard to these are given in Table VIII. In only 1 was pasteurized milk involved. In this instance the man running the small pasteurizing plant had a mild case of scarlet fever and undoubtedly contaminated the milk after it was pasteurized while bottling with a hand-operated bottling and capping machine. Strangely enough, of 3 supplies which he was pasteurizing only 1—the last run through the plant each day—was contaminated, and all the cases occurred on this milk route.

The per cent of the total number of cases of each disease reported in the state during each period which has been traced to milk is shown in Table IX.

TABLE VII
NUMBER OF COMMUNITIES MAKING BACTERIOLOGICAL EXAMINATIONS OF MILK

| Group | 1928 | | | 1931 | | |
|-----------------|-------------------------|---------------------------|-----------------------------------|-------------------------|---------------------------|-----------------------------------|
| | No. Answer- ing Item | No. Doing Bacteriology | Per Cent Doing Bacteriology | No. Answer- ing Item | No. Doing Bacteriology | Per Cent Doing Bacteriology |
| 50,000 and over | 17 | 16 | 94.1 | 17 | 17 | 100.0 |
| 25,000-50,000 | 11 | 7 | 63.6 | 13 | 8 | 61.5 |
| 15,000-25,000 | 22 | 14 | 63.7 | 17 | 13 | 76.4 |
| 10,000-15,000 | 15 | 9 | 60.0 | 17 | 9 | 52.9 |
| 5,000-10,000 | 30 | 9 | 30.0 | 26 | 12 | 46.2 |
| | 95 | 55 | 57.9 | 90 | 59 | 65.7 |

Milk-borne diphtheria has not occurred in the state since 1925, scarlet fever spread by milk has almost reached the vanishing point, and the per cent of typhoid traced to this source has reached the remarkably low figure of 0.4 per cent. The reason for the fairly large proportion of septic sore throat being traced to milk is obvious, since the disease is seldom recognized and reported except in epidemic form. A number of physicians in this state re-

* Includes typhoid fever, diphtheria, scarlet fever, and septic sore throat.

† First period in which septic sore throat was included. The large figures in this period, however, are due mainly to milk-borne scarlet and typhoid, details being given in the previous report referred to in the first paragraph of this paper.

‡ Listed separately so that figures since last report included in this paper may be followed through all the tables. Note that one period is 4 and the other is 3 years.

port sporadic cases which they claim to be clinically identical with those seen in epidemics.

In Table X is shown the number of outbreaks and the total number of cases of milk-borne disease during each 5 year period since 1895. The low figures at the beginning of the record are due largely to the lack of epidemiological investigation of outbreaks. Except in period 1906-1910 the large fluctuations have been due to septic sore throat.

DISCUSSION

It seems remarkable that actual figures do not show a decrease in the per capita consumption of milk. It was predicted when the milk questionnaires were sent out that they would show a material diminution in the use of milk. Two factors are perhaps responsible for its continued use under present conditions: (1) the often reiterated emphasis laid upon the necessity of including milk in the diet; (2) the fact that milk is at present prices one of the most economical foods obtainable.

The decrease in milk-borne disease during the 3 years covered, therefore, cannot be explained by decreased use of the product and it is hard to believe

that the low prevalence is entirely due to chance in the face of the fact that there has been a material improvement in the safeguarding of the supply. More of the milk has been pasteurized, the quality has been controlled by more bacteriological examinations and numerous communities have tightened up their regulations in regard to quality and sanitary control.

SUMMARY

1. Milk-borne disease has reached an extremely low figure in Massachusetts during the last 3 years.

2. The per capita consumption of milk is apparently the same as it was in 1928. That there has not been a decrease is no doubt due to the emphasis placed upon the nutritive and protective value of milk, and also to its present low cost.

3. The per cent of communities requiring milk to be pasteurized or from tuberculosis-free cattle has almost doubled, and 84.5 per cent of the population of the state lives in communities having this regulation.

4. It is estimated that 85 per cent of the milk supply of the state is now pasteurized.

5. There has been an increase in the bacteriological examinations performed to guard the quality of milk.

Test Room Studies in Employee Effectiveness*

C. E. TURNER, DR.P.H., F.A.P.H.A. (*Life Member*)

*Department of Biology and Public Health, Massachusetts Institute of Technology,
Cambridge, Mass.*

THROUGH the courtesy of the Western Electric Company, a report is presented here upon the public health aspects of certain studies in the conduct of which the writer served as consultant. The investigations have been too extensive to be encompassed adequately in this brief paper which will be limited to a description of this new type of industrial research and some of the major outcomes of the study.

The establishment of the test room study was the result of a 3-year investigation conducted by the company in coöperation with the National Research Council upon the relationship between illumination and the productivity of employees. A literal interpretation of the results would have suggested that poor illumination is desirable, for a comparison of two comparable groups of workers showed that those working with gradually reduced illumination had a higher output than those with ideal illumination. Such a conclusion would be obviously absurd.

What the investigation really showed was that the type of laboratory investigation which is possible in the exact sciences, where all but one factor can be controlled, is not possible in the study of human beings, and that other factors had entered the experiment which were

more important than illumination. This suggested to G. A. Pennock, now Assistant Works Manager, the desirability of undertaking a study of employee effectiveness under test room conditions in which all of the factors affecting the physical and mental status of the worker could be observed with the greatest possible completeness. The company sought to learn those conditions under which people work best. We wished to study the human energy flowing into the product in order that we might deal with it more intelligently.

In April, 1927, 6 experienced female operators, chosen at random, were removed from the department in which they were working to a small test room in the corner of a regular shop. Their work was the assembly of telephone relays and involved putting together a coil, an armature, contact springs and insulators in a fixture, and securing the parts in position by means of four machine screws. The girls were invited to the office of the Superintendent in charge where the plan and objectives of the study were explained to them. Although shy at this first meeting, they readily consented to take part in the study. They were expressly cautioned to work at a comfortable pace and not to make a race out of the test.

The working equipment in the test room was like that in the regular department except that there was a hole in the bench at the right of each girl's position into which completed relays

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

The Relay Assembly Test Room

were dropped. The relay falls through a chute actuating a flapper gate. The opening of the gate closes an electrical circuit which controls a perforating device which in turn records the completion of the relay by punching a hole in a moving tape. This tape moves at the rate of $\frac{1}{4}$ " per minute and has space for a separate row of holes for each operator. The punched tape furnishes a complete output record for each girl for each instant of the day. The tape mechanism also carries a bank of 5 message registers giving a numerical record of the total number of relays completed by each operator.

As we began the test, our objectives were stated in the form of 6 questions:

1. Do employees actually get tired out?
2. Are rest pauses desirable?
3. Is a shorter working day desirable?
4. What is the attitude of employees toward their work and toward the company?
5. What is the effect of changing the type of working equipment?
6. Why does production fall off in the afternoon?

Fairly good answers have been secured to all of these questions except No. 5. New questions have constantly arisen and some of them have been satisfactorily answered.

Some description may well be given

of the test room method as a means of research in industrial health and employee effectiveness. It is the observational method dealing simultaneously with many variables. Some factors can be controlled and made constant. One condition is changed at a time; but there are certain conditions which are not subject to experimental control. These must be watched carefully and inter-relationships established. Too often scientists have been guilty of the *post hoc, ergo propter hoc* fallacy. They have changed one condition and regarded it as the cause of all subsequent events. Such factors as the physical or mental health or the attitude of the employee cannot, of course, be accurately measured quantitatively. Over long periods of time, however, many factors can be satisfactorily evaluated by means of proper statistical procedures.

Disregarding the problems of placement and working equipment, it has been our assumption that the effectiveness of an individual will vary with (a) his bodily status or physiological efficiency (health, skill, endurance); (b) his mental state (contentment and freedom from worry, fear, anger, hate, shame, or other morbid preoccupa-

tions); (c) his zest for work (determined by the enjoyment in performing the work, the feeling of justice in his treatment, and the desire for securing reward).

TABLE I

| Period Number | Period Name | Duration |

| 18. | Same as No. 17, except Friday P.M. off | 15 " |

Beginning with Period 7, rest periods have begun at 9:30 in the morning and 2:30 in the afternoon.

Certain specific changes having to do with the length of the working day or week, with the introduction of rest periods and with the sitting position of the operators have been made. These are described in Table I.

At the beginning of the study, output records were kept for each girl in her regular department for 2 weeks without her knowledge. The girls were then moved to the test room where they worked for 5 weeks before any changes

in working conditions were introduced. The intentional changes subsequently introduced have not by any means been the only ones studied. The following statement presents other differences which we have recognized between test room and shop conditions.

In the test room, the group piece-work basis of payment paid each girl more nearly in proportion to her individual effort, since she was paid with a group of 6 instead of 100 or more. The girls in the test room assembled fewer different types of relays. The operators could read their exact output at any time from the recorder. The test room was not quieter; if anything, it was somewhat noisier than the regular department. New conditions of work provided an element of novelty. The girls realized that the experiment was receiving the attention of company officials, which meant that they were being noticed as individuals.

There has been a fundamental change in supervision. There was no group chief in the test room, but instead a "friendly observer" of the experiment. Discipline was secured through leadership and understanding. The girls were allowed to talk and to leave the bench whenever they liked; they were not compelled to pick up parts from the floor at the time they were dropped. An *esprit de corps* grew up within the group.

The girls were given physical examinations every 6 weeks. They objected to this at first but later each trip to the hospital became a "party."

Three types of records are kept in the test room in order that changes may be determined in (1) output, (2) the individual, (3) conditions of work.

1. Changes in production may be accurately measured and constitute one evidence of the effectiveness of the worker. By means of a conversion factor, all output data were expressed in terms of a single type of relay. From the output records previously men-

tioned, we have determined for each operator (1) the daily output; (2) the average hourly output at different times of day, for different days of the week and for different periods of the study; (3) average weekly output; (4) the number of defective relays; (5) the amount of repair work done. During the first few periods of the study, 15-minute output records were computed in order to study variability or uniformity of performance.

2. Data concerning *changes in the health, the habits, or the attitudes* of the operators have been secured from (1) physical examinations, (2) the comments of operators, (3) attendance irregularities, (4) occasional series for blood pressure and pulse rate records, (5) vascular skin reaction readings, (6) records of the hours of sleep, (7) social case records, (8) intelligence and dexterity tests, (9) questionnaires to reflect attitude toward working conditions, (10) diet records over certain periods.

3. *Changes in condition of work* have been indicated above. Records have also been kept of the types of relays assembled, the temperature and humidity of the room and any differences in the quality or methods of handling raw materials.

FINDINGS

The first specific problem which the test room sought to study was the effect of rest pauses which were introduced in Period 4. We did learn much concerning rest pauses but soon found that there was a continually rising output in the test room which was in large measure at least independent of rest pauses. At the end of 4 years, the individual operators had increased their output from 40 to 62 per cent. The relationship of this increase to rest pauses is shown in Chart I. It will be seen that output rose appreciably in Period 3 before rest periods were introduced. In Period 12, rest periods were entirely eliminated and during 12 weeks, output reached a new height. This continued and the unexpected increase in production which was independent of hours of work showed the absurdity of any experiment in which rest periods are introduced and changes in output ascribed to this cause without checking to see whether other factors

CHART I—Solid line shows daily output increase from one full-day period to the next full-day period. Dotted line shows the actual average daily output. The work periods indicated at the bottom of the chart are as follows: (1) regular department (2 weeks), (2) test room (5 weeks), (3) special gang rate (8 weeks), (4) two 5-minute rests (5 weeks), (5) two 10-minute rests (4 weeks), (6) six 5-minute rests (4 weeks), (7) lunch rest (11 weeks), (8) lunch rest and 4:30 stop (7 weeks), (9) lunch rest and 4:00 stop (4 weeks), (10) same as period 7 (12 weeks), (11) lunch rest and Sat. a.m. off (9 weeks), (12) same as No. 3 (12 weeks).

may have been responsible. With the reintroduction of rest pauses in Period 13, total output rose still further.

We inevitably became more and more concerned with the task of finding the explanations for the remarkably increased output. Was it because of better health or at the expense of health of the worker? Was it due to lessened fatigue? Was it due to changed pay incentive? Was it due to an improved mental state on the part of the worker, to the elimination of unhappy preoccupations, or a greater zest for work?

These studies gave us new knowledge of two types: (1) more information concerning the relative importance of fatigue, working conditions and mental attitudes as factors in the increased output; (2) specific information concerning the effect upon employee efficiency of certain specific factors like sleep, rest pauses, and sitting position.

It is impossible to present here the detailed statistical evidence upon which conclusions are based. These data may be found in the Progress Reports issued by the company and it is probable that many of them will be included in a summarizing volume which is in preparation. We give a brief statement of the more important findings and ask the reader to check the statistical evidence from the Progress Reports if he wishes to do so.

Let us first summarize the findings with respect to specific factors:

Rest periods were found to decrease the variability in output. They did not decrease total output but slightly increased it. (See Chart II, which shows output following the establishment of rest pauses in the test room and in 3 shop departments.) They reduced the amount of time which the operator voluntarily took away from her bench by about one-half. Single 10- or

15-minute rest periods in the middle of the half day were preferred to more frequent shorter rest pauses.

The physical examinations showed that the increased output was not at the expense of the *health* of the worker. The health of the girls remained constant or improved slightly.

The question naturally arose as to whether the increased output was due to muscular *fatigue*. The study of the

CHART II—The output for different groups of workers following the introduction of rest periods is compared with the output of a base period just before rest pauses were put into effect.

weekly output curve indicates that appreciable cumulative muscular fatigue does not exist. Vascular skin tests and pulse product readings were both taken to detect differences. They did not

This View of the Test Room Shows the Type of Bench, Working Equipment and Parts Used in Assembling Relays

show cumulative fatigue and the latter test indicated less fatigue in this group than among workers in other occupations who had been tested elsewhere.

It seemed likely that the more satisfactory *basis of payment* may have been a factor in increasing output. We sought to check this by setting up 2 other test groups. One group of relay assemblers was left in the regular department but paid as a small group. A group of mica splitters who had always been paid on a straight piecework basis were put in a test room. With Group I, we administratively changed only the pay incentive, although changes in attitude may also have taken place. With Group II, we provided test room conditions but did not change the pay incentive. The output in both groups went up over 10 per cent in a few months. We are inclined to believe that changed pay incentive may have been one factor in increasing output but it certainly was not the only factor.

An analysis of output on days fol-

CHART III—Comparison of output with hours of sleep showing an average of averages for 5 operators of the first relay assembly group. Figures in circles indicate the number of observations for each point.

lowing various amount of *sleep* showed that sleep has a definite, though not a dominant effect on output. Chart III.

A comparison of the output for the first hour after the operators changed from one type of relay to another with the average output for the first full

The Moving Tape and Counter for Recording Output

CHART IV—Percentage of efficiency in relationship to the length of the working week for operators 3 and 4 of the relay group. The types of working week in the different periods were as follows: (1) regular departments, (2) test room, (3) special gang rate, (4) two 5-minute rests, (5) two 10-minute rests, (6) six 5-minute rests, (7) a 15-

minute morning rest with lunch and 10-minute afternoon rest, (8) same as No. 7 with 4:30 stop, (9) same as No. 7 with 4:00 stop, (10) same as No. 7, (11) same as No. 7 with Sat. a.m. off, (12) same as No. 3 with no rests, (13) same as No. 7, (14) same as No. 11, (15) same as No. 13.

day following such a change showed that there is not a decrease in output immediately after so slight a *change in the nature of the work*.

Shortening the working week did not show an increase in hourly output but shortening the working day did show such an increase. Chart IV shows increases in efficiency when the week became shorter by reducing the length of the working day, but no increases when Saturday work was omitted. (Periods 11 and 14.)

The girls engaged in this type of work did not show a change in output during *menstrual periods*.

Changes in *sitting position* showed that the output of an operator is influenced by the workers sitting beside her.

Complete individual social case records were kept for test room employees. There is a definite relationship between output and satisfactory or

unsatisfactory *home conditions and social relationships*.

We at first thought that the *novelty* of test room conditions might be partly responsible for increased output but the continuing increase in production over a 4-year period suggests that it was not of great importance. In the judgment of the girls themselves, certain elements of the test room situation were listed in the following order of importance: (1) the small group, (2) the type of supervision, (3) earnings, (4) novelty, (5) interest of the girls in the experiment, (6) the attention given in the test room by officials and investigators.

In order to test the effect which the test room observer himself might have upon the group, the one who had been in the test room since its beginning was removed and his assistant placed in charge. The supervision in the test room remained approximately the same; there seemed to be no measurable

effect which could be assigned to the change in personalities.

SUMMARY

The phenomenal increase in the output of the original test room operators of from 40 per cent to 62 per cent, with less conscious expenditure of energy, indicates that a great deal more can be done to increase human productivity, with the lessening of the human energy cost (both physical and mental), without any change whatsoever in the set-up of the work itself. We know, from the physical examinations of the test room operators that their health status has not been impaired. We know, from our study, that muscular fatigue was, even in the beginning, an insignificant factor and has not since increased. We know, from our test room experience with these operators, that their mental tone and zest for work has increased tremendously. It should be remembered that these girls were working without critical supervision under the biologically natural situation of being allowed to work at their own pace without criticism because of fluctuating output instead of being expected to meet a given output every day.

We came to realize that neuromuscular fatigue is not of great importance in light industrial processes and that the mental attitudes of employees are of tremendous importance. Many questions remain unanswered but some contribution has been made toward a factual basis for employment management.

The test room method of research in this field is in itself a development of some significance and is likely to be used by industry in the future for the expansion of knowledge in the field of management and the study of human capacity.

Two specific outcomes of importance have resulted from the standpoint of company practices. After confirmatory tests in regular shop departments, rest periods have been successfully introduced in certain sections of the factory. The second and by far the more important development was the inauguration of an interviewing program in the shop departments and the development of the case method of instruction in supervisory training. In the test room we learned that mental attitude is important and we also learned much from employees' comments concerning the nature and importance of different factors in supervision and working conditions.

In order to secure the benefit of employees' reactions throughout the plant, a system of interviewing was developed in which the identity of the person interviewed was never disclosed but from which we secured valuable employee reactions upon which a changed attitude toward supervision has been built through the use of the case method in training present and prospective supervisors. The interview appears also to have contributed to the better emotional adjustment of many of the employers interviewed. Separate reports have been prepared describing the interviewing project.

Purification of Beet Sugar Wastes*

MAX LEVINE, PH.D., F.A.P.H.A.

Professor of Sanitary and Technical Bacteriology and Bacteriologist, Iowa Engineering Experiment Station, Iowa State College, Ames, Iowa

THE problem of treatment of beet sugar wastes in Iowa is complicated and aggravated by the fact that beet sugar manufacture is confined to a period of 3 or 4 months (October to January), of the year, and the low temperatures frequently prevailing at this season are detrimental to biological decompositions.

The wastes at the Beet Sugar Plant at Mason City, Ia., produced daily included:

Pulp or battery water, 700,000 gallons
Flume, wheel, or wash water, 3,500,000 gallons
Steffens waste, 200,000 gallons
Lime waste, 200,000 gallons

warm, generally about 45-46° C. The wheel water is the liquid employed in washing and fluming the beets. Its composition changes considerably as the season advances, and its temperature is generally low, frequently close to the freezing point.

COMPOSITION OF WASTE WATERS

The average compositions of these wastes for the year 1927 are shown in Table I.

The relative constancy of the pulp water and considerably increasing concentrations of organic matter in the wheel water as the period of operation progresses may be seen from Table II.

TABLE I
COMPOSITION OF WASTE LIQUORS FROM BEET SUGAR FACTORY (1927)

| Waste | Volume in Gallons | Analyses expressed as p.p.m. | | | | |
|----------------|-------------------|------------------------------|-----------------|----------------------------|----------------------|---------------------|
| | | Total Solids | Volatile Solids | NH ₃ and Org. N | O ₂ Cons. | O ₂ Dem. |
| Wheel water | 3,500,000 | 1,950 | 790 | 16.4 | 440 | 240 |
| Pulp water | 700,000 | 2,550 | 2,130 | 55.9 | 1,280 | 1,130 |
| Steffens waste | 200,000 | 21,900 | 12,800 | 969.0 | 3,410 | 3,580 |
| Lime waste | 200,000 | 42,100 | 15,200 | 145.0 | 3,290 | 1,440 |

The pulp or battery water is the liquid remaining after extraction and crystallization of the sugar. It is relatively constant in composition throughout the period of operation and quite

The oxygen demand results are particularly striking. Whereas the pulp water required 1,120 p.p.m. in October, 1,100 p.p.m. for the first 3 weeks, and 1,160 p.p.m. for the last week in December, the B.O.D.'s of the wheel water for the corresponding weeks were, 160 p.p.m., 385 p.p.m. and 720 p.p.m. respectively.

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

PURIFICATION EFFECTED BY PONDING PULP WATER

The purification effected by settling pulp water, and the combined pulp and wheel water wastes in open ponds will be briefly considered.

During the 1926 season, the pulp water was passed through a series of 5

shallow ponds covering an area of about 22 acres. The total storage period was approximately 12 days, the first pond accounting for 3 days storage.

It is evident that a 12-day sedimentation period through 5 ponds gave results only slightly better than obtained in 3 days through the first pond

TABLE III
EFFECT OF PONDING PULP WATER (1926 SERIES)

| Sample (Oct. 1926) | Storage Days | Vol. Sol. | Kj N | O ₂ Cons. | O ₂ Dem. | pH | Temp. °C. |
|-----------------------|-----------------|--------------|------|-------------------------|------------------------|-----|--------------|
| Pulp Water | 0 | 1,500 | 50.0 | 1,360 | 805 | 5.1 | 42.2 |
| 1st Pond Eff. | 3 | 510 | 37.5 | 212 | 565 | 4.5 | 20.4 |
| 5th Pond Eff. | 12 | 750 | 32.5 | 160 | 538 | 5.1 | 4.7 |

PER CENT REDUCTION

| | | | | | | | |
|----------|----|------|------|------|------|--|--|
| 1st Pond | 3 | 65.8 | 25.0 | 83.7 | 29.7 | | |
| 5th Pond | 12 | 50.1 | 35.0 | 89.1 | 33.1 | | |

—a reduction of 83.7 per cent oxygen consumed by settling in the first pond rose to but 89.1 per cent after passage through the series of 5. The B.O.D. reductions were only 29.7 per cent and 33.1 per cent after 3 and 12 days settling respectively. The relatively slight reductions in B.O.D. as compared with oxygen consumed effected by ponding are striking.

In the 1928 season several of the ponds (Nos. 1 and 2) were reconstructed so as to make 5 smaller but deeper ponds. The first of these had a capacity of 24 hours' storage of pulp water and the total storage period was estimated at a little over 4 days.

It may be seen from Table IV that considerable reduction in volatile solids and oxygen consumed is obtained by

ponding pulp water for 1 to 4 days, but that reductions in oxygen demand were very moderate. This was in line with the observation on ponding in 1926. On the basis of Table IV and other observations, it was found that settling pulp water in an open pond for 24 hours effected reduction as follows:

| | |
|-----------------|--------|
| Volatile solids | 50-62% |
| Oxygen consumed | 77-80% |
| Oxygen demand | 13-22% |

The reaction became distinctly acid during the 24-hour storage.

There are some reports in the literature that liming the settled pulp water to neutralize acidity would stimulate biological action and effect further purification. About 2 tons of lime per million gallons were added daily to the effluent from the pond receiving the

TABLE IV

† Pond A Effluent stored about 3.5 days in open ponds.

pulp water, and the mixtures allowed to flow through a series of ponds giving an additional storage period of about 3.5 days. The results are summarized in Table V.

The evidence is distinct that under the conditions of these observations liming was not beneficial.

PURIFICATION EFFECTED BY PONDING PULP AND WHEEL WATER

The total purification (B.O.D. reduction) effected by ponding the pulp and wheel water is indicated in Table VI, for the year 1927. At this time the pulp water was settled in 2 ponds for about 4 days, the wheel water in a third pond for about $\frac{1}{2}$ day, and the effluents from the pulp and wheel water ponds mixed and allowed to flow through 2 small ponds which provided an additional storage of 1 day. Reduction of 39.4 per cent to 48.2 per cent in B.O.D. were effected by this ponding system.

Dorr type of clarifier for a short period, (2) the efficiency of filters for purifying an effluent from such a settling tank, and (3) the possibility of using a washable filter for preliminary treatment.

The Dorr tank employed was an old type 2-story one. The wheel and pulp waters were brought to the tank and allowed to enter in a ratio of 5 to 1, at a rate which afforded an average detention period of about 1 hour. During the last few weeks the detention was not over 40 minutes because of loss of capacity due to accumulation of settled solids. The effluent from this Dorr tank was pumped to a small tank which served as a distribution box for dosing experimental filters. The waste was applied to filters by means of tipping troughs, which discharged the liquid onto perforated trays suspended about 6 to 9" above the top of the filling materials.

In one series of experiments the

Rate of application to filters 2,000,000 g.p.a.p.d.
Figures in () indicate over-all per cent reductions.

6' deep. The cinders were $\frac{1}{4}$ " or larger.

The results for a series of observations when the filters were dosed at 2,000,000 gal. per acre per day are summarized in Table VII.

Sedimentation in an old type 2-story Dorr tank effected reductions of 90 per cent in suspended solids and 33 per cent in volatile solids. The remaining suspended solids were quite objectionable from the standpoint of subsequent treatment by filtration on fine materials because of their clogging tendencies. Reduction of 48.7 per cent in organic nitrogen, 13.8 per cent oxygen consumed and 28.4 per cent oxygen demand were obtained by 1 hour settling.

Filtration of the settling tank effluent through 9' of quartzite resulted in over-all reduction of 75.7 per cent organic nitrogen, 65.9 per cent oxygen

consumed, and 75.9 per cent oxygen demand during the first month of operation (Table VII). During the second month of operation, after the filter had an opportunity to ripen, the efficiency increased considerably, to 95.4 per cent for organic nitrogen, 80.0 per cent oxygen consumed and 90 per cent oxygen demand. The coarser dolomite was about 20 to 25 per cent less efficient.

Coarse cinders ($\frac{1}{2}$ to 1 $\frac{1}{2}$ ") were particularly effective. When double filtration through 3' of a washable cinder filter was followed by filtration through 6' of cinders, reductions were obtained as follows: volatile solids 71.4 per cent, organic nitrogen 83.8 per cent, oxygen consumed 84.9 per cent and oxygen demand 93.2 per cent. The use of the washable filter markedly reduced clogging. Filtration through shallow cinder beds (3') was also very

effective, with reductions of 44.6 per cent volatile solids, 70.3 per cent organic nitrogen, 63.2 per cent oxygen consumed, and 73.4 per cent oxygen demand. Filtration through 3' of cinders was about as efficient as 9' of the relatively coarse dolomite (1-3").

A mixture of 1 part Steffen's waste to 20 parts of the effluent from the ponding system receiving both wheel and pulp water was applied to a cinder filter at 2,000,000 gal. per acre per day. The B.O.D. of the applied wastes varied from 290 to 680 p.p.m., the effluents from 4 to 76 p.p.m. The average B.O.D. of the applied wastes was 442 p.p.m., the effluent 30.3 p.p.m. or a reduction of 93.1 per cent.

SUMMARY

The paper is based on observations over a period of 3 years at a large beet sugar manufacturing plant, and includes a consideration of the relative efficiencies of ponding and biological treatment on trickling filters of various types.

The wastes which were subjected to study at the plant in question included

1. *Pulp or battery water* (about 700,000 gal. per day)—This is the waste water from the sugar, diffusion batteries and is generally very warm, (40-50° C.) and high in oxygen demanding constituents (800-1300 p.p.m. B.O.D.).

2. *Wheel water* (about 3,500,000 gal. per day)—This is the water used in fluming and washing the beets. It contains considerable mud, silt, etc., and its oxygen demand increases with progress of the manufacturing season from 150 to over 500 p.p.m.

3. *Steffen's waste* (about 200,000 gal. per day)—This is the liquid residue, from the Steffen's process for recovery of sucrose, and is very high in solids, (over 20,000 p.p.m. total, and 13,000 p.p.m. volatile solids) and in oxygen demand (3,600 to 5,000 p.p.m. B.O.D.).

Settling of pulp water in open ponds for 24 hours, effected reduction of 77 to 80 per cent in oxygen consumed, but only 13 to 22 per cent in oxygen demand. Volatile solids were reduced

by 50 to 62 per cent and the acidity rose from pH 6.6 to pH 4.5. The temperature of the effluents from the ponds varied on different years, but was always sufficiently high (22 to 32° C.) for efficient biological purification on filters.

Addition of lime (about 2 tons per 10⁶ gallons) to pulp water after preliminary settling did not produce better effluents than simple sedimentation, as respects B.O.D.

Ponding wheel water effected very considerable reductions in suspended matters (93 to 98 per cent) but little improvement as respects B.O.D. The wheel water temperature during the latter part of a manufacturing season may be so low that, after sedimentation in open ponds, the effluent may be close to the freezing point and unsuitable for efficient biological purification.

Passage of a mixture of 1 part pulp water and 5 parts wheel water through a Dorr thickener, of 1 hour settling capacity, effected reductions of approximately 90 per cent suspended solids and 50 per cent organic nitrogen. Filtration of the effluent from this Dorr thickener through 9' of quartzite at 2,000,000 g.p.a.p.d. (1½ to 1½") effected reduction as follows: volatile solids 72.4 per cent, organic nitrogen 95.4 per cent, oxygen consumed 80 per cent, and oxygen demand 90 per cent. Coarser filling material, (1 to 3") gave inferior effluents.

Coarse cinders (1½ to 1½") were found to be particularly efficient, effecting reduction of over 95 per cent when the mixed wastes were applied at 2,000,000 g.p.a.p.d.

Pulp water can be purified efficiently on trickling filters provided a suitable method for removing suspended solids could be devised.

Steffen's waste when diluted with 20 parts of other wastes, (pulp and wheel waters) was amenable to biological purification on trickling filters.

Administration of a Bureau of Tuberculosis in a City Department of Health*

H. R. EDWARDS, M.D.

Director, Bureau of Tuberculosis, Department of Health, New Haven, Conn.

THE first question raised by many departments of health relative to a bureau of tuberculosis in their organization is: Is it necessary? Why cannot the customary Bureau of Communicable Diseases handle tuberculosis as well as all other diseases of the same classification? Why cannot it be carried by the voluntary agency?

The reasons for a special bureau are:

1. Primarily tuberculosis is a chronic disease in contradistinction to most other communicable diseases. It requires longer periods of supervision, and that, in itself, means a different mode of attack and follow-up not needed in the average care of communicable disease.

2. Tuberculosis still holds an important place in our general death rate, taking its greatest toll during the early productive age periods of adult life.

3. The discovery, treatment, hospitalization and follow-up of tuberculous individuals and contacts have been responsible for the development of a huge aggregation of machinery that can hardly be utilized today to its utmost without some special training and understanding of the tuberculosis problem as a whole and in its integral parts.

4. The control of tuberculosis is primarily a function of the official health agency.

The organization and operation of a bureau of tuberculosis will add a minimum of \$5,000 or more annually to the budget of the department of

health, depending upon the scope of the services rendered. This factor automatically eliminates the smaller departments. To gain some idea of the size of the communities now operating bureaus of tuberculosis, the following list of cities is given.*

I. Cities Over 500,000 (13)

Buffalo, N. Y.
Cleveland, Ohio
Detroit, Mich.
Los Angeles, Calif.
New York, N. Y.
Philadelphia, Pa.
San Francisco, Calif.

II. Cities Over 250,000 to 500,000 (24)

Cincinnati, Ohio
Milwaukee, Wis.
Newark, N. J.
Seattle, Wash.

III. Cities Over 100,000 to 200,000 (41)

Duluth, Minn.
Fall River, Mass.
Grand Rapids, Mich.
New Haven, Conn.
Oakland, Calif.
St. Paul, Minn.
Syracuse, N. Y.
Yonkers, N. Y.

It is obvious that of the 88 cities of over 100,000 population, only a few have organized bureaus of tuberculosis, and the New Haven experience has shown that a bureau is practical in cities of 150,000 or more.

The functions of a bureau of tuberculosis are as follows:

* Read before the Health Officers Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

* This list was supplied in 1929 by the A.P.H.A. A more recent and complete list is not available.

1. To correlate, articulate, and lead the way in all local tuberculosis activities, official and voluntary.

2. To secure the prompt and accurate reporting of active cases and deaths.

3. To coöperate with other agencies in outlining educational campaigns for the discovery and control of tuberculous cases and contacts.

4. To keep an accurate check on the hospitalization of cases.

5. To tabulate and analyze morbidity and mortality statistics of tuberculosis.

In some communities the bureau may be responsible for hospitalization facilities, either through direct control of the institutions or power to subsidize existing facilities by the placing of cases in local general hospitals to await vacancies in sanatoria. Each community will present problems and conditions peculiar to itself; so the functions of the bureau will vary accordingly. In general, it may be said that a bureau of tuberculosis must interest itself in any project that will result in the eradication of tuberculosis in a given community.

Personnel—The minimum requirement would be a director and a clerical assistant. Other personnel depends upon the scope of the services undertaken, such as nursing, clinics, etc. The director should be a graduate M.D. in good standing, with special training in tuberculosis problems as an administrator and clinician, and his personality should command the respect of the local profession.

Ideally, the director should be on a full-time basis, though there are communities in which a part-time service is reported to be satisfactory. It would be better to have a good part-time than a poor whole-time director. There is sufficient work in any community capable of supporting a bureau to keep the director well occupied.

The duties of the director vary, but generally the following will be found applicable in almost any case, and for one with initiative and industry, in-

numerable openings will develop in which he can expand his program at will:

1. All policies of the bureau should be outlined by the director.

2. The director should be thoroughly conversant with the detail management of the office, and especially the record system.

3. He should accord consultation service for private practitioners, on both free and pay cases.

4. Educational activities should include the various forms of visual instruction for children and adults, newspaper publicity, lectures, magazine articles, etc.

The director should be the driving force behind the community's tuberculosis program.

A clerical assistant is necessary if the records are to be maintained. The success of the program will depend upon their accuracy and completeness, for it is this material that forms the foundations for expansion and the ultimate control of the disease.

Equipment—In addition to the usual office equipment the most important requirement is adequate filing facilities. Our experience has proved the economy of visible files, rather than the old vertical type, for active cases under supervision.

The average bureau will divide its cases in various ways: active, or those under supervision; inactive, or those moved or lost, and dead. Some subdivide their active files into clinically active, quiescent, and arrested. This latter subdivision is not of great value because of the difficulty in keeping the data accurate. It requires periodic check-ups on the clinical status of the patient that are almost impossible if the cases are not under the supervision of a trained tuberculosis clinician.

LEGISLATION

Public health and preventive measures cannot function without the backing of statutory laws and health regulations, enforceable by local courts. The same is true of tuberculosis.

Invariably, tact and diplomacy will sell more tuberculosis prevention than the invoking of laws. Nevertheless, situations arise when legal backing is absolutely necessary to the promotion of sound public health. The accuracy and persistency with which the local bureau does its work will determine the effectiveness of the letter of the law. The law requiring the reporting of tuberculosis is of no value unless an effort is made to make it so. Reporting will not necessarily be prompt after writing the physician a letter, or sending him a copy of the law. Every available source must be constantly checked to make sure that the physician has not forgotten; the same is true of sanatoria, hospitals, etc.

It is the responsibility of the bureau to make the law effective. If the bureau becomes lax, the observance of laws and regulations becomes lax. It is a matter of eternal vigilance. The following laws, rules and regulations should be on the statute books of the state, and in

the ordinances of the local community.

In many instances similar legislation exists, but it is antiquated and has no teeth, or no provision is made for enforcement. In such cases, the laws should be redrafted to meet the existing conditions.

1. Report in writing of all forms of tuberculosis to the local health officer within 24 hours after the diagnosis is made by: physicians, hospitals, sanatoria, undertakers, laymen, and others having knowledge of a case.

2. Report by hospitals, sanatoria, or other institutions caring for cases of tuberculosis, all forms, on admission and discharge; the discharge report, stating condition and destination of patient.

3. A law empowering the local health officer to hospitalize any case of tuberculosis considered a menace in the home in which he lives, or to the public at large. To work this effectively, a suitable place should be provided to which the courts can commit the recalcitrant case.

4. Either the practitioner indicates by his report that he will assume all responsibility for the proper supervision of the case, or that responsibility be assumed by the local health officer.

CHART 1

Laws prohibiting promiscuous expectation, common drinking cups, common towels, etc., are secondary to the foregoing.

Legislation is very important and requires expert opinion and advice.*

control of the personnel handling cases in each of the agencies in New Haven dealing with tuberculosis, he is supposed to be the articulating and directing head.

The plan, as started in 1926, is still

CHART 2

THE NEW HAVEN PLAN

The Bureau of Tuberculosis in the New Haven (Conn.) Department of Health was organized in 1926.¹ The Bureau of Tuberculosis is deemed to be the hub about which all tuberculosis activities in New Haven revolve, and while the director does not have direct

in operation. A group of specialized tuberculosis nurses previously under the director of the Bureau of Communicable Diseases was dropped and our nursing service was put under the New Haven Visiting Nurse Association on a generalized plan. The bureau subsidized the Visiting Nurse Association service with an amount equal to that paid for specialized service. As yet the Board of Health does not entirely pay for nursing service rendered. The municipal dispensary was abandoned and all

* *Technical Series, No. 8, A Manual of Tuberculosis Legislation*, by James A. Tobey, published by the National Tuberculosis Association, will give to those interested as full information on the subject as is possible in a general way.

coöperate and protect the rights of practitioners. As soon as a case is reported, the physician is asked if he wishes nursing service, and his reply is entered on the case record. Frequently we find that cases reported by practitioners as private have been known to the Visiting Nurse Association for some time, and it is this type that the practitioners so frequently criticise the nurses for interfering with. In general, however, the physicians are very coöperative and quick to turn to us for advice and aid in placing their cases. The percentage of new cases of the total reported to the bureau annually by physicians has increased from 22.3 in 1928 to 28.6 in 1931.

The bureau receives routine reports from the following sources, all of which are checked against our files and kept up to date.

1. Physicians
2. Bureau of Vital Statistics
3. Hospital admissions and discharges
4. Sanatoria admissions and discharges
5. City and State Laboratories—reports on sputa examinations
6. United States Veterans' Bureau—regional office in Newington
7. The New Haven Dispensary
8. Reports on X-rays made on the Department of Health plan

We receive a monthly report from sanatoria and most hospitals in addition

dispensary activities were centered at the New Haven dispensary, the outpatient department of the Yale School of Medicine. It is a polyclinic, centrally located and convenient to all transportation facilities, and is adequate for local conditions.

To facilitate coöperation, an Advisory Board of the Anti-Tuberculosis Program was created. It includes representatives of the various affiliated organizations, and its function is purely advisory. The recommendations of this board in most instances have been accepted and put into effect by the various agencies. The chairman is the Health Officer of New Haven, and the secretary, the director of the Bureau of Tuberculosis.

CASE FINDING

New Haven is fortunate in having legislation on the reporting of the aforementioned cases. It is not 100 per cent efficient and usually fails in the reporting of private pay cases under some physicians. Eventually, however, the majority of these cases do come to our attention. We have made every effort to

CHART IV
REPORTING OF NEW CASES TUBERCULOSIS
IN
NEW HAVEN 1931

dren—we endeavor to follow them until they reach 25 years.

To maintain these data, constant checking is required. All cases known to be under private practitioners are checked every six months for address and condition through the doctor. The remainder of our roster is checked through the Visiting Nurse Association, as they follow all other cases. Our files are checked annually against each new city directory.

A diagnosed case (pulmonary, childhood type, and other forms) is never dropped unless it moves out of town, is lost, or dies. The frequency of visits is determined by the clinical condition of the case. We are taking a similar attitude toward tuberculin positive chil-

All dispensary activities are centered at the New Haven Dispensary. There are 8 clinic periods each week, including 1 night period, 4 for adults and 4 for children. The pediatric division takes children from birth to 6 years, and the general clinic from 6 years up. The average number of visits per

registered case has never been over 2.3 for the past 4 years. This is below the American Public Health Association standards of 3.0, but we do not feel that our service is below that deemed necessary; in fact, we feel that we schedule return visits more frequently than is absolutely necessary. Approximately two-thirds of our cases on the dispensary roster are contacts, and with better than 2 cases hospitalized at all times for each annual death, there are few open cases in the community that need frequent dispensary supervision.

There are 2 trained tuberculosis clinicians at every clinic and 3 if the demand is sufficient. Thus every patient is able to be cleared within a reasonable time. In addition there are 2 fourth-year medical students working under the direction of the trained staff. The director of the Bureau of Tuberculosis takes part in 3 of the general clinics and thereby keeps in close touch with the cases handled.

The active files of the tuberculosis dispensary include all cases with a diagnosis of tuberculosis, the contacts to those cases, and all children with a positive tuberculin test. In the latter group an endeavor is made to examine all members of the family to determine if possible the original source of infection.

The polyclinic feature of the dispensary gives each patient who will follow advice, the opportunity of a complete diagnosis. Private practitioners may refer their cases for diagnosis, and on its completion a full report is made. If a dispensary case is found to be permanently under the care of a private practitioner, the physician is sent a complete résumé of our findings and recommendations.

The director of the Bureau of Tuberculosis is also available for consultation service with practitioners.

Other important clinical adjuncts are our X-ray service and free tuberculin.

The X-ray service is an arrangement with 4 prominent roentgenologists to take stereo films for a minimum of \$5 per pair, the patient paying \$3, and the Department of Health the balance. The only qualification is that patients recommended for this service shall be unable to pay standard fees, and be under the care of a practitioner. It is left to the doctor to decide. Duplicate reports are made on these films, one going to the doctor and the other to this bureau, which offers a basis for checking on diagnosed cases. The service has been in operation over 4 years and averages over 100 films a year.

Fresh dilutions of O. T. are prepared by our laboratory and supplied to physicians on request, free of charge. Physicians have been urged to use O. T. for all child contacts in families where a definite diagnosis has been made. It has not been used to its fullest capacity.

NURSING SERVICE

All of our nursing service is rendered by the New Haven Visiting Nurse Association on a generalized plan. They maintain a tuberculosis supervisor who is responsible for the tuberculosis nursing service in the various districts. Measured by A. P. H. A. standards, the Association has consistently given over 200 per cent of accepted standards in visits. We do not feel, however, that this service is overdone.

It was obvious from the outset that the generalized plan needed more emphasis on tuberculosis than was customary in such services; so a series of lectures on tuberculosis, beginning with a historical sketch, to the immediate problem in New Haven, was arranged for the entire staff. The lectures, 8 in all, were given by clinicians from the dispensary and sanatoria, and the director of the bureau, giving the nurses an opportunity of knowing the majority of the tuberculosis workers

handling their cases. They also spend time at the dispensary, at William Wirt Winchester Hospital (tuberculosis hospital), and visit one or more of the state sanatoria to familiarize themselves with the problem. New nurses added to the staff since that time have been given similar courses in groups.

This effort has been most productive in a broader appreciation of the problem on the part of the nurse and consequently a better service to the patient.

INSTITUTIONAL CARE

The Tuberculosis Commission, created by State Statute, is responsible for all sanatorium hospitalization in Connecticut. They operate 5 institutions with a total bed capacity of 1,222 (Sept., 1932). To this may be added 481 beds in other state, private, or semi-private institutions, a total of 1,703 beds. Connecticut reported an average of 932 deaths from tuberculosis (all forms) in the past 3 years—thus we have a ratio of 1.82 beds per annual death.

The state has opened 450 new beds between June and September, 1932. Previously the waiting lists ran as high as 450 for many months, meaning a waiting time of from 4 to 6 months. This proved to be a very serious hazard from the standpoint of public health and cure of the patient. The Department of Health secured an appropriation from the Board of Finance of New Haven to provide temporary hospitalization in local hospitals while patients were awaiting sanatorium vacancies. This service was administered by the director of the bureau and only those cases were taken who could not afford to pay the local charges of \$15 to \$21 per week, and that were deemed a menace in the home or to the community. In the majority of cases the department has to assume full responsibility. The total expenditures for this service from 1927 to September,

1932, were \$79,191.53. It is not the policy of the bureau to render this service, except in emergencies, if there are available vacancies in any of the state sanatoria.

The cost of care in state sanatoria is about \$24 per week, \$4 of which must be paid either by the patient, some agency, or the town in which he has a legal settlement. Thus in New Haven, the Department of Charities and Corrections assumes the \$4 minimum charge for state care in the cases of those unable to pay. A large number secure this basic cost by membership in the Employees' Tuberculosis Relief Association.

Despite the long waiting lists at our state sanatoria, New Haven has been able to provide hospital care for those who will coöperate. The one exception is the recalcitrant case, and we have been handicapped there in not having a hospital with commitment authority, but we have utilized the county jail in a few instances with good results. The problem requires additional sanatoria with restraining facilities with commitment to make it workable.

During the past 4 years we have maintained an average of 2 or more patients in hospitals and sanatoria for each annual death, and our performance in this item has been over 200 per cent of the quota established by the A. P. H. A. standards.

Additional institutional care for the tuberculous in New Haven is to be found in open window classrooms and a summer camp. The open window classrooms are operated entirely by the Department of Education. There are 7 in operation, with an enrollment of over 300 each year. Special consideration is given to contact children recommended by this bureau and the dispensary. A camp is operated 3 months each summer and it is in all respects comparable to a preventorium. The children are selected at the dis-

pensary; all have positive tuberculin tests; and the majority, some form of manifest glandular, a latent pulmonary, or childhood type disease. No child with open pulmonary disease is admitted. The camp reaches over 100 worthy children each year and is free.

The Employees' Tuberculosis Relief Association assumes a very active part in the New Haven program. It is a voluntary organization designed for the employees of industries in New Haven. Its income is derived from contributions from employees in some 50 or more industries, the industries themselves, and the sale of Christmas seals. The primary purpose of the Association is to pay the basic \$4 required by the state sanatoria, or a similar amount in other institutions. Their services are predominantly for relief and amount to about \$30,000 a year. They save the city about \$18,000 a year in sanatorium costs.

SPECIAL ACTIVITIES

Plans for the examination of school children by the use of tuberculin and X-ray have been under consideration for several years, but for financial reasons only a limited program was started in 1931. We were anxious to determine as nearly as possible the extent of the problem and the reaction of parents and children. Accordingly, we selected a single school³ and without excessive effort we received requests for tuberculin tests in 84 per cent of the enrollment, a figure that could easily have been exceeded if we had canvassed the homes. Thirty-eight per cent of those tested (563) reacted to the test; of the 215 X-rayed 53 showed evidence of disease, 18 were suspicious, and the remainder showed no disease. Thus the demand for this type of service was established.

This year a new plan is under way. We believe that the most potent source of new cases is to be found in our

junior high and high schools. We propose to drop the tuberculin test and use the new paper sensitized X-rays which can possibly be secured in mass quantities at about \$.60 a single film. This amount is so small that we feel there will be at least 50 per cent, or 5,000, in our junior high and high schools who can pay for it themselves.

BUDGET OF THE BUREAU OF TUBERCULOSIS

Our budget is made up of 4 chief items:

Salaries
Education, equipment and supplies
X-ray service
Hospitalization

The total money appropriated and expended since 1926 is shown in Table I.

TABLE I

| Year | Appropriation | Expended | Per Capita Cost |
|------|---------------|------------|-----------------|
| 1926 | \$5,250.00 | \$4,229.00 | \$.026 |
| 1927 | 6,866.00 | 5,915.00 | .036 |
| 1928 | 10,600.00 | 17,993.08 | .110 |
| 1929 | 25,650.00 | 24,351.00 | .149 |
| 1930 | 25,650.00 | 28,688.47 | .176 |
| 1931 | 28,750.00 | 34,641.39 | .212 |
| 1932 | 25,700.00 | | |

Bureau started September, 1926.

The increase in expenditures over appropriations is accounted for in the item of hospitalization made necessary by the urgent need of placing cases that were a menace in their homes or the community. The decrease of expenditures in 1929 under appropriation was due to our failure to use the entire amount available for temporary hospital care.

Replacement of Toxin-Antitoxin by Toxoid with a Consideration of the Comparative Dosage*

WILLIAM H. PARK, M.D., F.A.P.H.A.

Bureau of Laboratories, Department of Health, New York, N. Y.

LET us first consider to what extent a negative Schick test gives us a measure of the degree of antitoxic immunity of a child. Although we certainly know better, we are apt to think that a negative Schick test in a child indicates a high degree of immunity. Of course, it simply indicates that the child has at least $1/30$ th of a unit of antitoxin in 1 c.c. of its blood. This is sufficient to prevent infection; a greater amount might insure a longer average immunity. As the tissues of the majority of children are readily stimulated to make this amount of antitoxin, a single injection of 1 c.c. of toxin-antitoxin or of 2 antigenic units of toxoid will make about 40 per cent of them Schick negative. A repetition of the same amount will increase the percentage of those changing to a negative test to about 70 per cent; and a third injection to about 85 per cent. The actual amount of antitoxin in the blood can only be estimated by testing specimens of the blood for their power to neutralize a definite amount of toxin in guinea pigs. These tests are tedious but not difficult to carry out.

The relative immunizing value of toxoid and toxin-antitoxin—The results

of a number of tests are given in Table I.

TABLE I
COMPARATIVE IMMUNIZING VALUE OF TOXOID AND TOXIN-ANTITOXIN IN GUINEA PIGS

| Substance | First Injection Original Amount in c.c. | Second Injection | Total Antigenic Units | No M.L.D. Neutralized at end of 2 mos. |
|-----------------|---|---------------------|--------------------------|--|
| Toxoid | .0625 | | 0.6 | 3.0 |
| Toxin-antitoxin | .0625 | | Not Tested | 1.5 |
| Toxoid | .125 | | 1.25 | 7.5 |
| Toxin-antitoxin | .125 | | Not Tested | 1.5 |
| Toxoid | .250 | | 2.5 | 20.0 |
| Toxin-antitoxin | .250 | | Not Tested | 2.5 |
| Toxoid | .062 | .062 | 1.25 | 10.0 |
| Toxin-antitoxin | .062 | .062 | Not Tested | 3.0 |
| Toxoid | .125 | .125 | 2.50 | 40.0 |
| Toxin-antitoxin | .125 | .125 | Not Tested | 4.0 |

It is evident that while the toxin-antitoxin injections produced immunity, the degree of immunity was much less than in the guinea pigs getting the injections of equivalent amounts of toxoid. This was especially true when 2 injections were given. The increase in the amount of immunity produced is almost proportional to the amount of modified toxin and the number of doses given. The potency tests were made 6 weeks after the giving of the first injection.

The most suitable size of the injections—In children of less than 3 years of age, good preparations of toxoid create little disturbance when 1 c.c. is injected. This amount should contain

TABLE II

THE IMMUNIZING EFFECT OF DIFFERENT SIZED INJECTIONS OF DIPHTHERIA TOXOID

| <i>Number Injections</i> | <i>c.c.</i> | <i>Antigenic Units</i> | <i>Age of Children</i> | <i>Number of Children</i> | <i>Schick Retests Neg.</i> | <i>Pos.</i> | <i>Per Cent Immune</i> |
|------------------------------|-------------|----------------------------|------------------------|-------------------------------|--------------------------------|-------------|----------------------------|
| 2 | 0.12 | 2.5 | 6 mos.-5 yrs. | 90 | 82 | 8 | 91 |
| 3 | 0.12 | 3.75 | " " | 118 | 109 | 9 | 92 |
| 2 | 0.5 | 10.00 | " " | 496 | 468 | 28 | 94 |
| 3 | 0.5 | 15.00 | " " | 71 | 67 | 4 | 94 |
| 3 | 0.5 | 15.00 | 5-15 yrs | 243 | 228 | 15 | 94 |
| 2 | 1.0 | 20.00 | 6 mos.-5 yrs. | 210 | 204 | 6 | 97 |

The retests were made between 2 and 3 months after the first injection.

at least 10 antigenic units. In young people and in adults, the reaction from this amount is occasionally rather severe. About 4 per cent show a painful local swelling and some constitutional symptoms. These reactions are not in the least harmful, but they are annoying and sometimes create opposition to further treatments. When 1 c.c. is mentioned as a dose, we always mean of a standard toxoid, having about 8 to 10 antigenic units. It is a pity that the authorities do not require the number of antigenic units in 1 c.c. to be stated. Without the knowledge of the number of antigenic units the amount of fluid is meaningless. One might as well state that a Schick test was made with 1/10 c.c. of dilute toxin, instead of stating it was 1/50 m.l.d.

Toxoid is such a good immunizing substance that much less than 2 injections of 10 antigenic units each will suffice to produce a greater percentage of immune children than 3 doses of 1 c.c. of toxin-antitoxin.

Table II gives the results of injecting from 2/10 c.c. to 1 c.c. of a toxoid containing 10 antigenic units per c.c. In some children, 2 injections were given; and in some, 3.

It is noted that 2 injections, each containing only 2.5 antigenic units, changed the reaction in the children in 91 per cent of the cases. When the size of the injection was multiplied 8 times,

the percentage of children who developed enough antitoxin in their bodies to alter the Schick reaction was only moderately greater, because a small percentage of the children is always much more resistant than the majority. The average amount of antitoxin in them was markedly increased. As the toxoid causes no inconvenience in young children, it would seem wise to inject 10 antigenic units in each of 2 doses. There is a probability that in time we will have a preparation so active that one dose will be effective.

*The age of the children at which injections produce the best results—*Babies under 2 months old did not respond as well as those of older ages to the injections. Those between 3 and 6 months responded as well as those of greater age. I believe, however, that if larger numbers had been tested, the percentage of success would not have been quite so great.

TABLE III

THE IMMUNIZING EFFECTS OF INJECTIONS OF DIPHTHERIA TOXOID IN CHILDREN OF DIFFERENT AGES

| <i>Children Age</i> | <i>Number</i> | <i>Result of Retest Per Cent.*</i> | | |
|-------------------------|---------------|------------------------------------|-----------------|---------------|
| | | <i>Negative</i> | <i>Positive</i> | <i>Immune</i> |
| 1-2 mos. | 46 | 34 | 12 | 74 |
| 3-6 mos. | 50 | 48 | 2 | 96 |
| 7-12 mos. | 388 | 359 | 29 | 92.5 |
| 2nd year | 316 | 304 | 12 | 96 |
| 2-4 yrs. | 247 | 240 | 7 | 97 |
| 4-6 yrs. | 193 | 187 | 6 | 96.8 |

* These retests were made between 2 and 3 months after the first injection.

Table III gives some recent figures by my associates, Dr. May Schroder and Dr. Julius Blum.

It is evident that we can choose any month after the end of the second, but because of their tender age we will probably be wise to immunize the infants living in the country at the age of 6 months, since many of them are not immune; while in the city, 9 months will probably be the best choice, since 80 per cent to 90 per cent of the infants are immune because of their mothers' transferred immunity. This immunity is retained for from 7 to 12 months.

The interval between injections of doses of toxoid—We have given repeated doses to several thousand children. The intervals between the doses varied. The percentage of successful results conferred in children receiving injections at intervals of 1 week was somewhat less than that obtained at intervals of 2 weeks. Intervals of longer than 2 weeks between injections gave no better results. It seems, therefore, that when possible intervals of 2 weeks or longer should be preferred.

Effect of the addition of alum to the toxoid preparations—There is no doubt that the addition of 0.2 per cent of alum adds considerably to the efficiency of the toxoid preparations. This is probably due to the fact that the presence of alum in the solution of toxoid delays somewhat the rapid dispersion of the toxoid in the tissues. With a greater percentage of alum the toxoid is precipitated. This precipitate

when injected subcutaneously is slowly absorbed. Good results are claimed.

CONCLUSIONS

1. The manufacturers should be required to state on their labels the number of flocculation (antigenic) units in the amount in the syringe or vial, or the number of units per c.c.

2. Two doses of from 5 to 10 antigenic units each are sufficient to immunize from 90 per cent to 98 per cent of young children, and of a somewhat less percentage of older children. Even 2 doses of 2.5 units each will give us as much immunity as 3 doses of 1 c.c. of standard toxin-antitoxin. If by refining we are able to obtain a much stronger toxin which does not produce too much local irritation we may use one dose only.

3. Toxoid has an advantage over toxin-antitoxin in being much more stable.

4. An interval of 2 weeks, or longer, is advisable between injections, but where it is much more convenient to make the interval only a week it is proper to do so.

5. At any age after 3 months, infants respond well to injections of toxoid. The choice time in the country is probably at 6 months, or a little later; and in the city, 9 months or a little earlier. The difference in the most desirable age is due to the fact that in the country a smaller percentage of infants obtain passive immunity from the mothers than in the city.

AIR CONDITIONING AND VENTILATION

A RECENT issue of the *Public Health Reports*¹ calls our attention to the modern air conditioning system of ventilation employed in the Senate and the House Chambers of the Capitol at Washington, D. C. This article presents to the public health worker developments of a new science in his field—a science that has stirred the public imagination and shows much promise in its widespread application.

Air conditioning was evolved in response to the demands of industry, in an effort to overcome the influence of certain deleterious climatic conditions on the manufacture of weather-sensitive products. In recent years the science has been given added impetus by a new demand for its application in the field of ventilation for human comfort and efficiency, and we have witnessed the rapid growth of this new application of ventilation, as attested by the numerous installations in theaters, office buildings, trains; in fact, wherever people tend to congregate in large numbers. So much progress has been made in the development of equipment used in air conditioning that today we even find small units on the market for use in residences.

Our understanding of the basic principles of ventilation and the physiological responses of the human body to various atmospheric conditions has been greatly increased by the work of Professor Yaglou and his associates, in the establishment of the effective temperature scale and the winter and summer comfort charts. Although no single comfort standard can be prescribed to meet every need, we are in a position, as a result of recent research, to produce an indoor climate exerting a beneficial influence on our comfort and efficiency. Professor Huntington regards a certain type of climate as one of the essentials conducive to great progress. Such a climate need not necessarily be a pleasant one, such as prevails

in some of the sub-tropical regions of the earth, but should be one with stimulating qualities.

There is still a lack of agreement among students in this field as to what constitutes an ideal climate. We also lack sufficient conclusive data to indicate that certain air conditions optimum for comfort are identical with those for health, although on a general physiological basis the two are closely allied. The human body is capable of adapting itself to all sorts of atmospheric conditions; nevertheless, this adaptability is attained at the expense of creative and physical energy. Voluminous data have been gathered which indicate that there are optimum air conditions for comfort and that our ability to do work is greatly influenced by the state of the atmosphere.

However, many vexing problems confront the student of air conditioning in the field of ventilation for comfort. The optimum range of humidity is still a matter of conjecture, but all investigations on this subject indicate that this factor must be considered in conjunction with temperature.

Another problem to be solved is that of reproducing the natural climatic state of the atmosphere existing in an open country under ideal weather conditions. The secret of the stimulating quality of country air which is lost when the air enters indoors, especially when it is mechanically treated, has as yet not been disclosed. Ionization and ultra-violet light have been suggested as possibilities, and considerable work is now in progress on this question. The factor of environmental radiation has also been shown to be one of importance in the field of ventilation and is now receiving attention both in this country and abroad.

It is only hoped that research on the subject of air conditioning will not experience a lag at this time of our economic crisis, for it is only by a continuation of the excellent type of work already accomplished that we may hope to broaden our knowledge of this interesting and important phase of hygiene.

MILK AND MEAT INSPECTION IN THE UNITED STATES

THE American Veterinary Medical Association has for some years maintained a committee to study meat and milk inspection in the various states in the Union. At the last meeting a report¹ was made by Dr. Cary, the chairman, which is anything but encouraging. He explained that for 2 years he had been trying to get reports from the states as well as from a number of the cities. In many cases he wrote to 4 or even more men in a single state, and frequently got reports which were in conflict on many points. It was impossible for him to arrive at an accurate conclusion as to the status of meat and milk inspection in such cases.

He gives condensed reports from 42 states. In going over them, we are at once struck by the lack of systematized inspection, particularly of meat, but also of milk. We are no less struck by the difference in the laws of the various states and in the authorities which are made responsible for one or the other inspection, or for both—the state board of health, the state department of agriculture, the state department of public welfare, the bureau of sanitary engineering,

which is often under the state department of health, the state board of live stock commissioners, the bureau of animal industry.

In some, inspections are done to a certain extent by graduate veterinarians, and in some almost entirely by laymen. This is especially the case with milk. In one state it was considered that veterinarians are not well qualified as milk inspectors, and that the best work is done by chemists and bacteriologists. In others, so-called dairy specialists are employed, and in still others, a certain number of physicians do the work, or as much of it as is done. Some states have the same inspectors for both meat and milk, but the majority of them have different operators. In a number there is no state-wide law for either meat or milk inspection. Others have inspection for meat, but none for milk, or *vice versa*, though apparently those having some laws regarding milk inspection are in the majority. In almost all states, the cities are ahead of the state itself in inspection of milk, but it is rather astonishing to see how many states have neglected inspection. Even some which are in many respects more advanced than most are woefully deficient in the work done. For example, in Pennsylvania, the meat inspection law is administered by the Bureau of Animal Industry, but only 6 men are employed for the work, each having a district including from 8 to 13 counties. In this state there are some 3,000 slaughter houses, many of them small, but it is easy to see that 6 men cannot adequately do the work.

Under our system of government, the federal authorities have no right to do any intrastate work except on the invitation or permission of the local authorities and, needless to say, little is done. The report holds that we have the best meat inspection system in the world, and with this opinion we agree, but the inspection is necessarily legally limited to interstate and export work. In addition to the many small slaughter houses, a very large number of animals are slaughtered on the farm and sold without inspection of any sort. The report was "accepted" by the Association on the authority of the chairman and as his progress report.

As far as the inspection of milk goes, this is very largely left to local communities. Most cities have some sort of milk inspection. Some states have state-wide laws, but they are not enforced. Indeed, few if any states have a sufficient force of men to carry out proper milk inspection for all cities and towns, even if they wished to do so.

As is known, the U. S. Public Health Service began the development of what was then called the "Standard" Ordinance in 1923 and, in one way or another, the adoption of this has been widely urged on communities over the country. A survey has recently been made by an Englishman² for the Health Section of the League of Nations, who correctly says that this ordinance has met and is still meeting strong opposition. It points out that the reports are open to bias, and that since the surveys made have been carried out under the federal government, and the method of assessment was such as to favor cities working under the ordinance, too much weight cannot be attached to the findings. The author of this report recognizes that under our governmental system the Service has no authority to force the ordinance on any state or city, and since its application demands greater financial expenditures, higher standards of vigilance, activity, and mental honesty than are to be found in many towns, there is little likelihood of its uniform adoption in the near future.

We can safely say in conclusion that while conditions have improved tremendously over what they were even 10 years ago, and while we believe that they are still improving, much is left to be desired. With the exception of our federal

service, our inspection of slaughter houses, as well as of meat and milk, in practically every part of the United States is in a condition of flux.. It is hard to suggest a remedy other than intensive and extensive education, but according to the report before the Veterinary Medical Association, only a limited number of schools are giving really worthwhile instruction in these matters. The same can also be said of medical colleges without much fear of contradiction. The public must be educated to demand these things and trained to realize that expenditures along these lines are investments for safety which may be regarded as the best form of life insurance.

EATING UTENSILS AS A SOURCE OF INFECTION

IN the prevention of disease we often make the mistake of looking too far away for the source and neglecting everyday affairs directly at hand. For some years certain companies and certain cities have insisted upon the physical and bacteriological examination of food handlers. Unquestionably many sources of infection have thus been eliminated.

Attention has also been directed to the sterilization of eating utensils.¹ In some cases these are washed clean but infected later by the handlers. A striking example of this was the epidemic of typhoid fever² among university students at Madison, Wis., in which a waiter who suffered from a walking case of typhoid fever, wiped and stacked dishes after they had been washed, and infected some 41 persons. He finally died, after suffering severe headache for some 3 weeks, for which he consulted an optician.

In New York City an investigation of 1,980 food handlers in 1917 showed 10 active and 15 arrested or suspected cases of tuberculosis, 19 active and 32 suspected cases of syphilis, and 6 of gonorrhea. Other examinations have revealed similar conditions, and it seems not only possible but probable that patrons of restaurants have been infected through such means. It is said that in certain establishments where soft drinks and ice cream are served, glasses and spoons have nothing which can be called washing, but are simply rinsed, drained, and used again sometimes without drying. Even in high-class restaurants finger bowls are used over and over by different patrons without even being rinsed in between. The single service paper cups and finger bowls have done a good deal to rectify such conditions, but there is still much to be desired.

The mechanical dish washer is coming into more or less general use in hotels and restaurants, and bacteriological examinations show that the results are much better than hand washing, except in those cases where the latter is done with extreme care, with really hot water and soap, and with clean and hot rinse water. When the rinse water is only lukewarm, there is absence of disinfecting action, and in a short time, becomes rich in bacteria. With hand washing the tendency, of course, is to use water which is not hot enough to scald the operator.

The examination of restaurant apparatus referred to was carried on in Montreal, and showed that rinse water at temperatures from 37° to 47° C. contained members of the colon-aerogenes group. As the temperature of the water was increased, the number of bacteria diminished, but even at 55° C., a certain

number of bacteria persisted, though none of the colon group were found. On the other hand, when utensils were cleansed and sterilized by boiling water, the total counts were very low, and members of the colon-aerogenes group were absent. Further experiments showed that properly conducted machine washing gave better results when the utensils were dried in the air than when a towel was used. The total obtained from the examination of 6 types of tableware dried in the air were 34 bacteria for air and 327 for towel drying. Similar results were obtained in homes and clubs, and advantage being markedly in favor of air drying.

Bacteria are transmitted to eating utensils by handlers, and the types are largely determined by whether or not these handlers are infected with some contagious disease. They may be in the nasal secretions and saliva, and be coughed or sneezed on to utensils, especially those like cups, spoons and forks, which also come into direct contact with the mouth. The whole study emphasizes that there is undoubted evidence of the transmission of certain communicable diseases through the medium of improperly cleansed and disinfected eating utensils, both in private homes and in public eating places. There is good reason to believe that the conditions in Montreal are not unlike those elsewhere, and may be accepted as representative. The sanitary arrangements in many hotels and restaurants are much below the accepted standards for cleanliness and safety. Mechanical dish washing is better than any method of hand washing. There should be a better inspection of eating places.

THE SIXTY-SECOND ANNUAL MEETING INDIANAPOLIS, OCTOBER 9-12

A GLANCE through the preliminary program of the scientific sessions of our Sixty-second Annual Meeting illustrates again that there is no diminution of study and research in times of depression, nor any reduction in the quality or quantity of scientific writing.

The program follows the traditional pattern of breakfast, morning, luncheon, dinner, afternoon, and evening meetings, beginning Monday morning, October 9, and continuing through Thursday, October 12.

The successful Health Education Institute held at Washington for the first time will be repeated this year, the theme of five sessions being "The Psychology of Health Education." Attendance is to be definitely limited to 60.

We have become accustomed to the presence of a number of related associations and groups at our meetings. This year we shall have many old and some new friends with us. The old ones include the American Association of School Physicians, the Conference of State Sanitary Engineers, the Conference of State Laboratory Directors, the Association of Women in Public Health, the American Social Hygiene Association, the International Association of Medical Health Officers. The International Association of Dairy and Milk Inspectors were missed at Washington, and we can expect them in the future only in alternate years. This year they return to us again; attending the Laboratory session on Thursday morning, participating in a joint meeting with the Food and Nutrition Section on Thursday afternoon, and beginning their own independent meetings on Friday.

The Indiana State Nurses Association and the Indiana League of Nursing Education, new to us, will meet with our Public Health Nursing Section on Thursday afternoon and continue with their individual sessions Friday.

The American Social Hygiene Association is building a joint program with the Child Hygiene Section for Thursday morning and will conduct a Regional Conference for a day and a half thereafter.

The ten sections of the American Public Health Association have already prepared material for 42 sessions, and the end is not yet in sight. The keynote of the meeting appears to be one of intense practicality. The titles of the papers and reports indicate the brass-tack thinking that health workers these days necessarily must do.

Members of the Association are urged to make their hotel reservations early. The July *Journal* will publish hotel rates, railroad rates and further program details.

*Sixty-second Annual Meeting of the American Public Health
Association, Indianapolis, Ind., October 9-12, 1933,
Headquarters, Claypool Hotel*

ASSOCIATION NEWS

INDIANAPOLIS LOCAL COMMITTEE

EXECUTIVE COMMITTEE

General Chairman—William F. King, M.D.

Vice Chairman—Walter F. Kelly, M.D., President, Marion County Medical Society

PUBLIC HEALTH ADMINISTRATION

Racine, Wis.—For this city of 69,333 individuals, the Health Commissioner has prepared a mimeographed report of 47 pages, the usefulness of which is materially enhanced by a generous index. The Racine Health Department has 47 on its pay roll, of which 21 are employed by the Health Department itself, 9 in the Lincoln Hospital, and 17 in the Garbage Collection and Incineration Divisions.

The death rate in 1932 was 7.9 per 1,000 which is the lowest ever recorded in this city. The splendid activities for health promotion and the special effort to prevent diphtheria has been continued in keeping with the policy of previous years. There were 17 cases of diphtheria reported, the lowest number in over 20 years. There were 2 deaths from this cause, 1 occurring in a young woman who was brought to the City Hospital for treatment and died within a few hours of admission. In neither instance had the individual received any preventive treatment. There was no case of smallpox in 1932 which proved, however, to be a measles year with 2,648 cases and with but 1 death.

Milwaukee, Wis.—As a city of good health, Milwaukee has maintained its splendid record and distinction. In 1931 this community was again awarded first place in its population group for cities participating in the National Inter-Chamber Health Conservation Contest. During the 3 years of the Contest, Milwaukee has been awarded first place on 2 occasions. A new low death rate of 8.8 was recorded in 1932. The Health Commissioner reports that the average age at death is now 52.6 years. He com-

pares this present figure with the average age of death in 1880 which was 18.1 years, in 1900 when it was 27.6 years, and in 1920 when it had reached 38.7 years. A low infant death rate of 46 per 1,000 births is reported for 1932, a year in which there was not a single death from typhoid fever. The diphtheria prevention program has been continued, through special emphasis in Child Welfare Clinics and by utilizing a portable bus clinic.

Smallpox Incidence—The U. S. Public Health Service in its *News Letter* for April 18, reports a very noticeable decrease in the incidence of smallpox in the United States during the past 2 years. The number of cases reported in 1930 was 48,907; in 1931 there were 30,232 cases and in 1932 only 11,168. The number of cases for 1932 represents but 27.8 per cent of the average for the preceding 4 years. For the first 13 weeks of 1933 there were reported 2,413 cases compared with 5,280 cases for the same period in 1932.

English Health Insurance—In 1908 the report of the Royal Commission on the Poor Law appeared and, like the recent report of the Committee on Costs of Medical Care, it contained a majority and a minority report, both of which agreed in that medical service to the poor people was most unsatisfactory and that something ought to be done about it. The majority recommended the establishment of a system of poor dispensary while the minority recommended the extension of the work of public health authorities. The English government, however, adopted

neither recommendation but introduced a plan of compulsory health insurance.

This plan, which became effective in 1912, involves two basic principles: first, that private insurance medical practice should resemble private medical practice as far as possible; and second, that the scheme should provide each insured person with the services of a family physician. At present there are 15,000 insurance physicians in England and Wales who are serving 15,000,000 insured persons.—George F. McCleary, English Health Insurance and the Standard of Medical Service, *Quart. Bull.*, Milbank Memorial Fund, Apr., 1933.

Epidemic of Typhoid Fever in Chamberlain, S. D.—An epidemic of 285 cases of typhoid fever occurred in Chamberlain, S. D., in the winter of 1932-1933. There were 31 deaths, giving a little over 10 per cent fatality rate. Chamberlain is a town of 1,300 people, situated on the bank of the Missouri River. This epidemic was undoubtedly due to the use of raw river water which had been insufficiently chlorinated. The water is taken from the Missouri River through an intake located about 150 ft. from the bank and flows by gravity into cisterns located under the pumphouse. The water is then pumped to a settling basin, the effluent then being chlorinated and pumped into the service mains. The water is not filtered. This procedure is followed except for a few months in the winter when the settling basin freezes up, in which case the raw river water is chlorinated and pumped directly into the mains. Shortly before the outbreak the settling basin was cut off and only chlorinated raw water was furnished the city. The Missouri River contains such a large amount of silt and organic matter that it is difficult to maintain the proper residual chlorine to render the polluted water potable. The

amount of chlorine which was being added previous to the epidemic was so small that it had little effect on the potability of the water.

At the beginning of the epidemic Dr. A. E. Bostrum, Epidemiologist, W. W. Towne, Sanitary Engineer, and the Assistant Director of the laboratory of the State Board of Health, went to Chamberlain to investigate and take charge of the epidemic. A temporary laboratory was set up to make diagnoses, check water and milk supplies, release patients, and to carry on such research as was indicated in an attempt to locate the exact source of contagion.

The water supply was rendered safe by the addition of large quantities of chlorine so as to maintain a high residual. It was determined that this high residual was necessary to maintain a potable water. Changes were made in the settling basin so it could be placed in operation.

Milk supplies were inspected and pasteurization of all milk and dairy products required. Regulations were enforced regarding the sale and distribution of dairy products. A milk ordinance was drawn up and submitted to the city officials. This was later passed and put into effect. It required the pasteurization of all milk.

A voluntary immunization clinic was established by the State Board of Health. More than 3,200 people in Chamberlain and surrounding territory were immunized. This does not include the number immunized by private physicians.

Money for food, clothing and fuel was obtained from the Reconstruction Finance Corporation. This made possible the cleaning up of the town and reconstructing the sewage system inasmuch as the men were furnished material things for their labor.

An emergency hospital was established in the City Hall and operated by the Red Cross, 38 patients being cared

for in this hospital and about 35 in the Chamberlain Sanitarium.

Due to the large number of cases developing so rapidly the local physicians were unable to care for their patients and outside physicians, mainly those from Mitchell, S. D., voluntarily came and assisted the local doctors.

The value of immunization was clearly demonstrated in this epidemic. There were 87 ex-service men living in the community who had not been immunized since 1918. Only one of them developed typhoid fever and his case was very mild.

The epidemic of typhoid fever at Chamberlain is the largest typhoid outbreak in the history of the State of South Dakota and probably one of the most concentrated epidemics that has occurred in the United States for some time. The City of Chamberlain has had bad water for a number of years, and the State Board of Health notified the city authorities of this fact and urged that they remedy the situation. The Board of Health in this state has no authority to force the city to improve its water supply. The people living along the Missouri River have the erroneous opinion that the river water is potable inasmuch as they think the water purifies itself in a very short distance.

The experiences of Chamberlain should be a lesson to all municipalities that they cannot economize in public health and expect to benefit by it. It is an expensive lesson and it is hoped that other communities will profit by it.

A complete and detailed report of this epidemic is now being prepared for publication.—Charles A. Hunter, Ph.D., Assistant Director of State Health Laboratory and Professor of Bacteriology and Hygiene, University of South Dakota.

Boston, Mass.—The 1932 annual report of the Boston Health League

directs attention to the increasing use of the census tract data throughout the city. Boston is divided into 128 census tracts. The unit of population is, therefore, extremely small in some areas making comparison of rates difficult. The Health League, Council of Social Agencies and the City Health Department have, therefore, agreed upon 14 permanent health and welfare districts based upon the census tract divisions. In the future, the Health League will prepare morbidity and mortality figures by health and welfare areas as well as census tracts.

The infant mortality study for 1930 was the first to be done by health and welfare areas according to census tracts. The study was published in the *New England Journal of Medicine* in August. In December a similar study of the 1931 infant mortality figures appeared in this *Journal*. Reprints are available from the League. Although a 2-year period is too short a time to draw final conclusions, the League has been much interested in the varying rates for different sections of the city, and an intensive study is being undertaken at present in Charlestown and the West End.

Orange County, Calif.—In 1932, the district health unit of Orange County became a complete county unit inasmuch as the last incorporated area was included in the health program. This unit reaches the 13 cities and the unincorporated area. Another forward step was made, coöperation was established between the health department and 3 school districts for a joint nursing service, "thereby avoiding the chance for duplication of effort and waste of time which might result from employing 2 nurses to carry on very similar programs in the same community."

In the face of a one-third reduction in budget, resulting in the loss of nurs-

ing and sanitary personnel, the department found more difficulty in the exercise of control of communicable diseases. The increase in cases reported was also accompanied by a tendency of families to refrain from calling physicians unless the illness became serious. There were 22,756 health department home visits in connection with the communicable disease work. During the year 2,000 children received protective treatments against diphtheria and 1,034 were vaccinated.

Cincinnati, Ohio.—The city manager's report for 1932 states that every attempt was made to keep the physical city in prime condition. Crime and accidents were reduced, disease and infant mortality declined, while opportunities for healthful play and community cooperation increased during the year. A council of 9 members, according to charter, determines the policies of the city.

The physical examination of 49,661 elementary school children revealed 70,396 defects, of which 40,546 were classed as "remedial." Underprivileged children whose parents are financially unable to correct these defects, are cared for by district physicians, clinics, and hospitals. In one high school, a routine fluoroscopic and X-ray examination of the chests of all pupils was inaugurated.

The task of aiding the indigent sick increased markedly during the year. During 1931 the medical staff carried 10,407 home patients, made 17,499 home visits, besides serving 5,753 office patients who made 8,538 visits. In 1932, there were 16,952 home patients who received 23,385 home visits. In addition to 16,093 office patients with 21,299 office visits.

The Bureau of Sanitation and General Food Inspection was established, effecting a saving of \$5,100 a year by the consolidation of two activities.

Among noteworthy statistical records are the infant mortality rate of 54.7 in 1932, as compared with 71 in 1931, and the tuberculosis death rate of 87.2 in 1932, as compared with 111 the previous year.

San Diego, Calif.—The first public health department report under the provisions of the new city charter, for 1932, notes the appointment by the City Manager of the 5 members of the Public Health Commission and the Director. Special attention is directed to the surprise milk contests conducted by the state and to the scores obtained by the city of 96.5 per cent and 97.4 per cent in 1932. This local department highly endorses these contests which have been held for 11 years with 21 contests. The published results of the contests have built up a rivalry among milk distributors which has extended back to producers in improving the milk supplies.

A decline in communicable disease incidence, continued decrease in diphtheria deaths, with a forward program of immunization, are noteworthy results of the year. The County Medical Society, with plans proposed by the pediatric section of the State Medical Society, appointed a Pediatrics Committee to cooperate with the child hygiene division of the local health department in the conduct of preschool conferences.

Maplewood, N. J.—Maplewood, with a population of 22,000, was one of the winning communities in its population class in the 1931 Health Conservation Contest of the U. S. Chamber of Commerce. For the first time in 14 years, the community was free in 1932 from cases of diphtheria. This experience is accredited to the protection of children by immunization procedures. In 1929 there were 29 cases of diphtheria with 3 deaths, as contrasted with

6 cases and no deaths in 1930, and 3 cases and no deaths in 1931. The immunization campaign was inaugurated in 1929. A large proportion of preschool children and 81 per cent of school children have been given protection.

During the year 1932 there were 1,326 visits of children to infant welfare clinics. Special hours were arranged for immunization of preschool children against diphtheria and vaccination against smallpox. Baby foods were distributed in order to assist with formula and cod liver oil is provided for those unable to purchase these health foods.

As part of the routine health work, letters are sent parents with the birth certificate, stressing the importance of preserving this record for future reference. When the baby is 6 months old, another letter is sent, urging that protection be given the child against diphtheria and smallpox. Just before the child is of school age, another letter advises the parents to have dental and physical examinations made to correct possible defects.

It is gratifying to note that all of the dairy herds supplying milk have been tuberculin tested and that over 99 per cent of the supply is pasteurized, the remainder being of certified grade.

Los Angeles County, Calif.—A new health and welfare center was opened in February in Torrance, Calif., to serve over 60,000 persons residing in an area of 60 square miles. This health center is the eighth building of a chain extending through the county to bring preventive services with complete equipment and specially trained staffs to neighborhoods in a plan to decentralize

the activities of the County Health Department.

Constructed along the modern Californian style of architecture which is essentially Andalusian Spanish in theme, the Torrance Health and Welfare Center has an aspect of unpretentiousness and cheerful invitation which is calculated to dispel the mechanical impression usually received from a public institution. A California padre tile roof covers the entire building which is constructed of brick and finished with white stucco. Colored glazed tile in the recesses under the larger windows and waist-high in the reception room lends an atmosphere of shiny cleanliness with warm hospitality which is in sharp contrast with the dead white so frequently used in buildings devoted to the promotion and conservation of health.

The building was erected at a cost of \$42,615, out of the annual county health department budget. The value of the equipment is estimated at \$9,400. The site for the health center, comprising almost 3 acres of choice property, was given to the county by the City of Torrance.

Peoria, Ill.—The death rate in this city decreased from 12.3 in 1931 to 10.7 in 1932. All communicable diseases showed a marked decrease with the exception of diphtheria. There was a mild epidemic of chicken pox during the last 4 months of the year. A survey made in October showed that about 20 per cent of the preschool children and 48 per cent of the school group through the fourth grade had been protected against diphtheria. By January 1, these percentages had increased to 30 and 58 respectively. The physicians of this community are coöperating by providing immunizations in their own offices each Saturday morning for \$1 per treatment with the understanding that when the physician feels that the parents are unable to pay, the service will be performed without charge. A Schick test is made on the same basis.

LABORATORY

A TEST FOR REACTION-PRODUCING SUBSTANCES IN CONCENTRATED ANTIPNEUMOCOCCIC SERUM*

Preliminary Report

L. A. BARNES, PH.D., AND S. D. KRAMER, M.D.

Antitoxin and Vaccine Laboratory of the Massachusetts Department of Public Health, and the Department of Preventive Medicine and Hygiene of the Harvard Medical School, Boston, Mass.

THE occurrence of chills following the therapeutic use of certain lots of concentrated antipneumococcic serum is an objectionable feature for which there is, as yet, no satisfactory explanation. Frequently, an abrupt rise in temperature is noted subsequent to the chill. Although not all lots of serum give rise to these reactions, it appears that they may occur occasionally in spite of recent improvements in concentration and refinement.

In the preparation of concentrated serum, various methods have been employed in attempts to eliminate the chill-producing substances without serious decrease in the potency of the product.^{1, 2, 3, 4, 5} The technic involves, as a rule, chemical or physical fractionation of the serum. Felton has reported some differences between reactive and non-reactive serums, particularly in the amount of protein precipitable at pH 4.6 to 4.8 and in the content of ammonia, and non-protein nitrogen.

Three lots of concentrated antipneumococcic serum, prepared at the Massachusetts Antitoxin and Vaccine Laboratory during the past year, serve as a basis for experiments to be reported in this communication. Lots

CP 28 and CP 29 were concentrated by the Felton alcohol method,⁶ while CP 30 was prepared by his sodium sulphate method.⁷ Lots CP 29 and CP 30 contained the same original serums, half of each bleeding going into each of the two lots. The serums were bivalent, containing both Type I and Type II antibodies. On the basis of physical appearance and potency all three lots were quite satisfactory. Following clinical use, however, it was found that CP 29 was practically chill-free, CP 28 produced moderate chills in only a low percentage of cases, while CP 30 gave more or less severe chills in a high percentage of cases. These data are shown in Table I.

Chills following the use of CP 29 were all mild and of relatively short duration; only one of those following injection of CP 28 was reported as severe. It was believed that these two lots were satisfactory for continued use. Felton considers a serum chill-free if these reactions occur in less than 20 per cent of cases.⁸

Comparative chemical tests performed with CP 29 and CP 30 showed no significant differences in content of ammonia, non-protein nitrogen, total nitrogen, amino nitrogen, total solids, or ash. The opinion has been held that an "acid fraction" of serum, precipitated

*Read before the Laboratory Section of the American Public Health Association, at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1917.

TABLE I

CHILLS AND TEMPERATURE RISES IN HUMAN CASES OF LOBAR PNEUMONIA FOLLOWING THERAPEUTIC USE OF CONCENTRATED ANTIPNEUMOCOCCIC SERUMS

| Serum Lot | Date Prepared | Period Used | Number of Cases | Number of Reactions | | Percentage of Reactions | |
|-----------|---------------|------------------|-----------------|---------------------|------------|-------------------------|------------|
| | | | | Chills | Temp. Rise | Chills | Temp. Rise |
| CP 29 | 11/2/31 | 2/ 8/32— 6/2/32 | 93 | 10 | 0 | 10.75 | 0 |
| CP 28 | 6/19/31 | 10/25/31—3/22/32 | 36 | 6 | 1 | 16.66 | 2.77 |
| CP 30 | 11/5—16/31 | 2/ 5/32—5/ 7/32 | 24 | 16 | 5 | 66.66 | 20.83 |

by adjusting the reaction to pH 4.6 to 4.8, contains most of the chill-producing substances.¹ No additional precipitate was obtained from either of these lots by such treatment. When diluted with progressively increasing amounts of physiological salt solution or normal horse serum, there was more precipitation with CP 29 (the "chill-free" lot) than with CP 30 (the "reactive" lot), thus making the possibility of protein precipitation in the blood stream remote.

Intravenous injections of the three

serums into rabbits produced chills and rises in temperature regardless of the lot used.

Following a suggestion by Drs. Bigelow and Heffron, experiments are being conducted with monkeys, (*Macacus rhesus*) to differentiate, if possible, reactive from non-reactive serums. Twelve monkeys have been used for testing CP 28, CP 29, and CP 30. The results are encouraging and are given in Table II.

It should be noted in Table II that CP 29, which produced only mild chills

TABLE II

CHILLS AND TEMPERATURE RISES IN NORMAL MONKEYS (*MACACUS RHESUS*) FOLLOWING INTRAVENOUS INJECTIONS OF ANTIPNEUMOCOCCIC SERUMS

| Serum Lot | Monkey Number | Weight in grams | Date Tested | c.c. Serum | Reactions | |
|-----------|---------------|-----------------|-------------|------------|-----------|----------------------|
| | | | | | Chills | Temperature Rise (F) |
| CP 29 | 832 | 3012 | 4/4/32 | 5.0 | No | 0.1 |
| | 835 | 2589 | 4/6/32 | 5.0 | No | 0 |
| | 866 | 1770 | 7/1/32 | 10.0 | No | 2.4 |
| | 867 | 2058 | 7/1/32 | 5.0 | No | 3.6 |
| CP 28 | 830 | 2258 | 4/4/32 | 5.0 | Yes | 3.1 |
| | 833 | 3298 | 4/6/32 | 5.0 | Yes | 0.8 |
| | 807 | 3483 | 4/8/32 | 2.0 | No | 0 |
| CP 30 | 831 | 2754 | 4/4/32 | 5.0 | Yes | 2.0 |
| | 834 | 3808 | 4/6/32 | 5.0 | Yes | 1.8 |
| | 811 | 2400 | 4/8/32 | 1.0 | Yes | 2.2 |
| | 817 | 2640 | 4/8/32 | 0.5 | Yes | 2.0 |
| | 820 | 2765 | 4/8/32 | 2.0 | No | 1.5 |
| | 832* | 3012 | 4/6/32 | 5.0 | No | 3.1 |

* No. 832 had been injected 2 days previous with 5.0 c.c. of CP 29 and had no reaction, so was retested with CP 30 to serve as a control.

in 10.75 per cent of human cases, gave no chills in monkeys injected with 5.0 c.c. and 10.0 c.c. doses; CP 28, which was somewhat more reactive than CP 29 in human beings (16.66 per cent chills), produced chills in 2 monkeys given 5.0 c.c., but not in 1 receiving 2.0 c.c. CP 30, the chill-producing lot (66.66 per cent) in human patients, produced chills in 4 of the 6 monkeys tested, with doses ranging from 0.5 c.c. to 5.0 c.c. The 2 monkeys, 820 and 832, which failed to develop chills following the injection of 2.0 c.c. and 5.0 c.c. respectively, may have been unusually refractory animals, corresponding to unusually resistant human beings. While the number of animals used in testing this lot of serum is too small to draw definite conclusions, it is

of interest that the percentage of chills was the same as that in the human cases treated.

It may be of some significance that marked temperature rises occurred in monkeys 866 and 867 following the injection of CP 29 approximately 3 months after the first tests with this lot. The opinion has been held for some time that chill-free serums may develop reactive properties upon aging. This idea is shared by Sabin and Wallace.⁸ These authors also believe that a temperature rise of 1.5° F. or more (in dogs) is the criterion for determining reactive substances.⁹ It may be possible that the pyrogenic substances are precursors of the chill-producing materials. In tests on monkeys recorded above, the presence or absence of chills

TABLE III

CHILLS AND TEMPERATURE RISES IN NORMAL MONKEYS (*MACACUS RHEBUS*) FOLLOWING INTRAVENOUS INJECTIONS OF ALCOHOL-SOLUBLE AND ALCOHOL-INSOLUBLE FRACTIONS OF CP 29 AND CP 30

| Serum Fraction | Monkey Number | Weight in grams | Date Tested | Dose c.c.* | Reactions | |
|--|---------------|-----------------|-------------|------------|-------------------|-----------------------|
| | | | | | Chills | Temperature Rise (F). |
| CP 29 Alcohol Soluble 2nd Preparation | 869 | 1,635 | 7-1-32 | 10.0 | No | 5.1 |
| CP 29 Alcohol Insoluble 2nd Preparation | 861 | 2,045 | 6-24-32 | 10.0 | Yes | 2.3 |
| | 862 | 1,866 | 6-24-32 | 5.0 | Yes (very slight) | 1.5 |
| | 868 | 2,379 | 7-1-32 | 7.2 | No | 2.9 |
| CP 30 Alcohol Insoluble 1st Preparation | 848 | 2,430 | 6-2-32 | 5.0 | Yes | 2.0 |
| CP 30 Alcohol Soluble 1st Preparation | 850 | 2,705 | 6-2-32 | 5.0 | No | 2.4 |
| CP 30 Alcohol Insoluble 2nd Preparation | 851 | 2,329 | 6-8-32 | 10.0 | Yes | 4.6 |
| | 853 | 2,571 | 6-8-32 | 2.0 | Yes | 2.5 |
| CP 30 Alcohol Soluble 2nd Preparation | 852 | 2,469 | 6-8-32 | 2.0 | Yes | 1.8 |
| | 854 | 3,040 | 6-8-32 | 10.0 | No | 0 |
| | 859 | 1,800 | 6-24-32 | 10.0 | Yes | 2.3 |
| | 860 | 2,008 | 6-24-32 | 2.0 | Yes | 1.6 |

* The amounts given are in terms of doses of the original concentrated serums.

appears to be of more significance than rises in temperature. If, however, pyrogenic substances are related to chill-production, and the former appear earlier than the latter, a possible explanation is afforded for the temperature rises in monkeys 866 and 867 mentioned above. It would suggest further that CP 29 may later become a chill-producing serum. In this connection, it is of significance that the first 29 human cases during approximately the first 6 weeks of use of this lot, had no reactions. After this period, about 1 of every 6 patients had chills.

It has been suggested that reactions from antipneumococcic serum resemble, in some respects, those brought about by histamine-like substances. The following experiment contradicts this assumption. Alcohol-soluble and alcohol-insoluble fractions were obtained from CP 29 and CP 30. The alcohol-insoluble fractions showed approximately the same protective powers as the original serums, while the alcohol-soluble parts had little or no protection. These fractions were injected into monkeys in amounts calculated to correspond to doses of the original concentrated serum. The results of these tests conform to a large degree to those obtained following the injections of the original concentrated serums. It appears that both the alcohol-soluble and insoluble fractions of a chill-producing serum produce reactions in monkeys, while similar treatment of an essentially chill-free serum does not appreciably alter its reactivity. The details of the experiment are given in Table III.

SUMMARY

The production of chills and rises of temperature in 12 normal monkeys (*Macacus rhesus*) by intravenous in-

jections of three lots of concentrated antipneumococcic serum corresponded closely to the responses observed in human cases of lobar pneumonia treated with these serums. A serum essentially chill-free in human beings failed to produce untoward symptoms in monkeys; a serum mildly reactive in human patients, produced chills in certain doses in monkeys but not in a smaller amount; a third serum causing chills in two-thirds of the pneumonia patients treated, produced similar reactions in 4 of 6 of the monkeys injected. Intravenous injections into monkeys of alcohol-soluble and alcohol-insoluble fractions of a reactive and a non-reactive serum elicited responses similar to those following the administration of the original concentrated serums.

NOTE: This is one of a series of studies being conducted under a grant from the Commonwealth Fund of New York.

VITAL STATISTICS

Typhoid Fever Mortality in 1931-1932—Morbidity and mortality rates from typhoid fever differ more from one country to another than do the rates for most contagious diseases. The fact that in certain countries the cases and deaths are more accurately diagnosed and more faithfully reported than in others is not sufficient to explain these differences. Indeed, it is in those countries where the registration of cases of infectious diseases and the statistics of deaths are most complete that typhoid appears to be most rare, for it is certain that in many of these countries the services and the registration of medical statistics have progressed together.

If the death rate per 100,000 population from typhoid and paratyphoid fever is considered, the various countries may be grouped in several categories. The lowest typhoid death rates are observed in Germany, England and Wales, Scotland, Norway, New Zealand, the Netherlands, Sweden, and Switzerland, where rates of 1 per 100,000 or less prevail. These countries have reached their present level by a gradual reduction of typhoid mortality during recent decades. In England and Wales, for example, mortality from typhoid fever was no less than 37.4 per 100,000, during the years 1871-1875, and was still in excess of 6 in 1911. The situation was much the same in the Netherlands and in Germany. In the latter two countries, a recrudescence took place during the war, and persisted until 1921. With these exceptions, the countries belonging to the first group contrast with the others in the stability of their death rates, which as a general rule show only very insignificant fluc-

tuations from one year to another. It is interesting to note that the higher the typhoid mortality in a country, the greater will be the extent of the annual fluctuations in the rate. In other words, wherever the incidence of endemic typhoid is highest, the possibilities of epidemics are greatest.

Among the countries whose death rates fluctuated between 1 and 2.9 may be cited Australia, Austria, Denmark, the Irish Free State, Northern Ireland, and the Union of South Africa. Belgium, France, Canada, and the United States have death rates varying from 3 to 4.9.

The United States and Canada have shown a parallel evolution during the last two decades, the mortality in the U. S. Death Registration Area falling from 21 in 1911 to 9 in 1921, and to 4.5 in 1931. The Canadian curve, however, made a very noticeable jump in 1927, when the death rate rose to 11.6, owing to a milk-borne epidemic in Montreal. The geographical distribution of the typhoid fever mortality in the United States is distinguished by the maintenance of high death rates in the southern states as compared with the northern—*e.g.*, 2 of the North Central States, Minnesota and Wisconsin having rates of 0.6 and 0.7 respectively. In the south, on the other hand, Tennessee showed a rate of 10.7, West Virginia 12.6, Louisiana 14.5, South Carolina 16.6, and Georgia 16.7. These high rates in the southern states, however, do not mean that no progress is being made, for a considerable improvement has taken place during recent years, the rates in Tennessee and South Carolina having exceeded 20 previous to 1927.

The countries with a typhoid mortality ranging between 5 and 9.9 per 100,000, include Czechoslovakia, Poland, and Uruguay. In Czechoslovakia, after a severe outbreak in 1920, the death rate from this disease fell rapidly from 30.8 in that year to less than 10 in 1922, and finally to a new low level of 5.7 in 1932. Complete figures are available only for the Polish towns with a population of over 100,000 inhabitants, these towns having followed a course identical to that of Czechoslovakia: a maximum mortality in 1920, with 34.3 typhoid deaths per 100,000 population, and a mortality of less than 10 in 1930 and 1931. In 1932, however, a very marked rise occurred in Poland.

Among the countries whose present death rate is between 10 and 14.9 per 100,000 are Chile, Spain, the Straits Settlements, and Japan. Chile has been in this category only since 1929. Previous to that year, the typhoid mortality in this country was much higher, nearly always exceeding 40 per 100,000, and sometimes reaching a considerably higher level. The Spanish curve, after undergoing very wide fluctuations, showed an upward movement from 1911 to 1921, and fell sharply after that. The Japanese curve at first showed an almost constant rise until 1924, when typhoid fever exacted a toll of 24.8 deaths per 100,000, and since then the death rate from this disease has dropped considerably, reaching a rate of 10.9 in 1932.

Among the countries with a mortality of over 15, Greece, Hungary, Italy, and Portugal must be mentioned. For Italy, the curve has been sloping downward since the end of the war. It reached 30 deaths per 100,000 in 1918 and fell to a death rate of 15.6 in 1930. In Hungary, typhoid mortality, which was slightly in excess of 20 in 1913, reached its maximum in 1916 with a rate of 44.4 and decreased after that year to

a rate of 13.8 in 1925. An increase then occurred, reaching its culmination in 1929 (21.2). A fall in 1930 and 1931 was followed in 1932 by a considerable epidemic outbreak, the rate rising to 29.4. The epidemic was particularly severe in the northeast section of the country. Portugal experienced a rise in typhoid fever mortality during the war, reached a maximum in 1921 and has fluctuated since then around a rate of 20 per 100,000. In Greece, the mortality rate from typhoid fever has declined to its 1921 level of about 24 per 100,000, after having shown a marked rise to 32.5 in 1923.—League of Nations. *Epidemiological Report of the Health Section of the Secretariat. Month. Rep. No. 1-2*, pp. 3-6 (Jan.-Feb.), 1933.

Preliminary 1933 Edition of Accident Facts—Preliminary reports to the National Safety Council indicate that about 88,000 persons were killed in accidents during 1932, compared with a total of 97,415 in 1931. Of these 88,000 persons, 29,500 were killed in automobile accidents, 18,000 in other public accidents, 28,000 in home, and 15,000 in industrial accidents.

The estimated death rate from accidents for last year was 70.5 per 100,000 population, compared with 78.5 in 1931. The 1932 rate was the lowest in the history of the United States except for the years 1921 and 1922, when the rates were 68.4 and 69.6, respectively. The total number of deaths was smaller than in any year since 1924, when 85,684 deaths occurred. It is the second time that total accidental deaths have dropped since 1921.

Deaths in motor vehicle accidents declined during 1932, for the first time in history. The estimated total for the year was only 29,500 deaths, compared with 33,740 in 1931. There were 12,542 deaths in 1920; 21,877 in 1925.

This decline in motor fatalities of approximately 13 per cent means a saving of over 4,000 lives compared with 1931. The estimated death rate per 100,000 population from motor vehicle accidents in 1932 was 23.6, compared with 27.2 in 1931; this is the lowest recorded since 1928 when the rate was 23.3. The death rate per 100,000 cars registered was 121.5, compared with 130.7 in 1931; this is the lowest since the 1929 rate of 116.6. The rate per 10,000,000 gallons of gasoline consumption was 20.6, compared with 21.9 in 1931; the 1932 figure is a new low. In other words, the 1931-1932 percentage decline in motor vehicle deaths was about twice as great as the 6 per cent drop in motor vehicle registration or the 6.84 per cent decline in gasoline consumption (comparative 10 months' figures). Since these two factors are the best indicators of motor vehicle travel, it seems certain that the 1932 drop in deaths was due partially to a real advance in the safe use of streets and highways.

Forty-two states and the District of Columbia (total population 120,000,000) have reported comparable 1932 and 1931 figures. Of this entire group, Delaware and the District of Columbia were the only ones to show increases in 1932. The decrease was slight in some states but amounted to more than 20 per cent in others. North Dakota had the lowest death rate, 8.8 per 100,000 population, followed closely by Mississippi with a rate of 10.1. Nevada, on the other hand, had a rate of 56.7, California 39.9; and Delaware 35.0. While reports for the latest months of the year are missing from some states, complete 12 months' reports from over 100 cities also show a decline of 13 per cent. Cities with populations of over 500,000 had a drop in fatality of about 10 per cent, while smaller cities declined over 15 per cent. Milwaukee had the lowest death rate among cities

over 500,000, Rochester led the second group, and Peoria the third. Medford, Mass., with a population of 64,300, is the largest reporting city to have gone through the entire year without a motor vehicle death.

About 28,000 persons were killed in home accidents during 1932, a reduction of about 3 per cent from the 1931 total of 29,000. The 1932 estimate is based on representative city reports, which show a smaller decline in home fatalities than in any other of the principal classes. Falls and burns were responsible for about 60 per cent of all home deaths, while asphyxiation, suffocation, and poisons accounted for another 15 per cent. About 30 per cent of the victims were children under 15 years, many of these deaths resulting from burns, suffocation, and poisons. The mortality was high, also, among elderly persons, where falls were responsible for most of the deaths. On the basis of the ratio (experienced by insurance companies) of 150 non-fatal home injuries for each fatality, there were, roughly speaking, 4 million non-fatal home injuries in 1932.

There were about 15,000 industrial deaths in 1932, a reduction of 14 per cent from the 1931 total of 17,500. The estimate is based chiefly on the reduction in deaths reported to Industrial Commissions in 16 states, but as agricultural accidents are seldom reported to the Commissions it was necessary to estimate them separately. The state records show a decrease of 18 per cent, while the few available data on farm deaths indicate that there has been no decrease in the past several years.

Much of the decrease in accidents during the past 2 years was due to the great decreases in employment. However, records of member companies of the National Safety Council show that accidents have dropped even more than exposure. The number of lost time in-

juries per million man-hours worked dropped more than 50 per cent from 1926 to 1931, and the days lost per 1,000 hours worked declined over 30 per cent during the same period. The gains from 1929 to 1931 are exceptionally large.

Deaths in public accidents where a motor vehicle was not involved numbered approximately 18,000 in 1932. This is a 10 per cent drop from the 1931 estimate of 20,000, the decline being indicated by detailed reports from large cities throughout the country. The decrease shown for accidental deaths of this type was not quite as large as that shown for motor vehicle and industrial accidents. Drownings made up about 30 per cent of all fatalities in this group, railroad accidents (not motor vehicle) 16 per cent, and firearms accidents 11 per cent. The death rate from drowning dropped 37 per cent from 1910 to 1920, but since then little progress has been made. Firearms deaths have shown little change in the past two decades.

During the school year 1931-1932, accidents to school children numbered 9.4 per 100,000 student-days, and each accident resulted in 3.6 days lost from school. In the preceding 2 years the frequency was 10.3 and the average loss 3.0 days. Thus, during the last year there were fewer accidents, but on the average they were somewhat more serious. — National Safety Council. *Public Safety*, 7:4-11. (Feb.), 1933.

Deaths from Beriberi in Japan—Statistics show that beriberi is one of the important causes of death in Japan, especially among infants. During the 10-year period 1920-1929 there were in Japan, on the average, 17,000 deaths from beriberi annually, showing an average annual death rate of 29.4 per 100,000 population. Of the annual deaths from this cause, 62 per cent were among males and 38 per cent among

females. At ages 0-4, there was very little difference in the sex distribution, but during the years of adolescence, the disease was noticeably more prevalent among males. The sex discrepancy was at its maximum at ages 45-70, when 84 per cent of the deaths were among males.

Mortality from beriberi was highest in the first year of life when the death rate was 416 per 100,000; among infants the greatest number of deaths occurred in the second month of life, and thereafter fell progressively. At ages 2-9, the mortality was negligible; at ages 20-24 it rose to about 25 per 100,000; and at ages 40-80 it was about 11-13 per 100,000. The deaths showed marked seasonal distribution, rising in May and reaching their peak in autumn. In fatal cases three-fourths of the deaths followed an illness of less than 1 month. The death rate from this cause in the large towns was twice as high as in the small towns and rural areas.—H. Maki, *Observation statistique des deces causes par le beriberi au Japan propre*. *Kitasato Arch. Exper. Med.*, 1932, v. 9, 202-17. Abstr. by A. Bradford Hill in *Bull. Hyg.*, 8:140 (Feb.), 1933.

The Homicide Record for 1932—The homicide record in the United States for 1932 shows no material variations from the record for the year before. As measured by the results for 31 American cities with an aggregate population of 25,000,000 in 1932, the homicide rate remained at exactly the same figure as for the previous year—10.8 per 100,000, which compares with a rate of 9.4 for 1922 and 8.3 for 1912.

Homicide returns tabulated by the U. S. Bureau of the Census for 36 cities, which in 1929 had a collective population of 27,000,000, show that in 1900 these cities had a homicide rate of only 3.4 per 100,000, the rate increas-

ing to 8.4 in 1920 and by 1929 to 9.8. This rate is almost triple that of 30 years ago. The whole U. S. Death Registration Area showed homicide rates of 8.7 per 100,000 in 1927; 8.8 in 1928; 8.5 in 1929; 9.0 in 1930; and 9.3 in 1931.

Although the returns for 1932 for the whole country are not yet available, preliminary returns furnished by local boards of health for 180 American cities (which in 1932 had an estimated population of 42,481,911) showed that the rate for this group of cities in 1932 was 10.5 per 100,000 against 10.7 for the previous year, a small decrease not suggestive of much progress in crime prevention or control.

Analyzing the returns for the 180 cities, it appears that in 70, the rate increased, and in 92 the rate declined, while in 18 it remained the same. The returns showed 8 cities with rates in excess of 40 per 100,000. All of these are southern cities and the victims in most cases were negroes. As has been the case for some years past, Memphis heads the list with a homicide rate of 54.2, which is over 5 times the average rate for all the cities represented in the entire tabulation. The Memphis rate unquestionably is unduly increased by the exceptional frequency of admissions of outside murder patients to local hospitals, a condition which cannot be avoided, without the allocation of deaths according to the scene of crime. Equally amazing is the high rate for Lexington, Ky., which ranks next to Memphis, with a rate of 53.6 for 1932, as against 36.8 for 1931. Jacksonville, Fla., had a rate of 52.2; Little Rock, Ark., 44.8; Montgomery, Ala., 43.6; Charleston, S. C., 43.5; Savannah, Ga., 42.2; and Birmingham, Ala., 40.8.

In gratifying contrast to these southern cities with high homicide rates is the record of 21 cities without a single homicide in 1932: and of these, 7 had none in 1931. The rate for Boston,

Mass., has declined from 3.6 in 1931 to 2.5 in 1932, a remarkably low rate for a city with nearly 800,000 inhabitants. Worcester, Mass., has likewise a very low rate for 1932—only 2 per 100,000. The low rates for Portland, Me., and Providence, R. I., are of special interest because the death penalty has not prevailed in Maine nor Rhode Island for many years. Providence in 1932 had a homicide rate of only 1.2, while the rate for Portland was only 2.8. The death penalty has been abolished in Wisconsin, where in the city of Milwaukee, the homicide rate in 1932 was only 3. Capital punishment is not enforced in Minnesota; the homicide rate for Minneapolis was only 4.4, while that of St. Paul was 3.6.

Comparison of the 1932 and 1931 homicide rates for the 5 largest cities of the country shows rates of 12.8 and 14.1 per 100,000 for Chicago; rates of 9.6 and 10.8 for Detroit; 8.4 and 7.0 for Los Angeles; 8.0 and 8.3 for New York; and 7.8 and 7.2 for Philadelphia, for the 2 years 1932 and 1931, respectively. The actual number of homicides in the 5 largest centers of population combined decreased from 1,485 to 1,464; in other words, the crime situation, collectively considered, remained practically stationary. Chicago, alone of these 5, had a rate above the average for the country at large.

The high homicide rates for southern cities suggest a brief reference to the racial aspects of the problem. In 1929 (there being no later returns), the homicide rate of the U. S. Death Registration Area was 5.2 for the white population, and 38.1 for the colored, an extraordinary difference, explicable chiefly on racial grounds and the negro's inclination to deeds of extreme violence on slight provocation, but the high negro rates usually correspond to comparatively high rates also for the white population, as shown in the following comparison for selected cities.

In 1929, Atlanta showed a homicide rate of 14.1 for the white population as compared with 109.8 for the colored; Birmingham—rates of 17.8 and 89.7; Dallas—7.9 and 52.7; Louisville—7.3 and 84.7; Memphis—11.8 and 144.2; and New Orleans—11.1 and 64.0.

The southern states present practically the same situation in regard to homicides as reflected in statistics of southern cities. In 1929, Alabama recorded rates of 8.7 per 100,000 for its white population, and 39.0 for colored; Arkansas—7.7 and 37.6; Florida—11.7 and 59.0; Georgia—8.4 and 34.9; Kentucky—11.4 and 72.3; Louisiana—7.0 and 32.7; Mississippi—10.2 and 36.0; and Tennessee—7.3 and 58.6.

By way of comparison, study of 13 Canadian cities with an aggregate

population of 1,875,194 in 1932, shows a homicide rate in this year of 1.3 per 100,000, the rate having declined from 1.6 in 1931. Eight of the cities in this group had no homicides at all in 1932. Toronto with a population corresponding to that of leading cities in the United States, had the highest homicide rate—one of 2.2 per 100,000, Winnipeg ranking next with a rate of 1.8.

The deplorable situation in the United States in regard to homicides appears even worse when compared with the rate in England and Wales, where during the years 1921 to 1931, homicides did not exceed 0.7 death per 100,000 population; and in 1931, there were 0.5 homicides per 100,000.—Frederick Hoffman. *The Homicide Record in 1932. Spectator* (Mar. 30), 1933.

PUBLIC HEALTH ENGINEERING

New Type of Sewage Distributor—The new Dorco distributor, for applying settled sewage evenly over circular trickling filters, is described and illustrated. The distinctive feature of the distributor contributing more to its efficacy than any other single item, is the adjustable, flat spray type of nozzle used. The sprays wet overlapping areas, assuring complete utilization of bed surface at each revolution and also absence of dry spots, effectively preventing breeding of flies.

The nozzles are readily adjusted, both as to volume of sewage passed and the shape and thickness of the spray. The distributor may be fed either from an automatic dosing siphon or directly by a pump. In either case satisfactory operation may be secured with a head of 12 inches of water, the reaction of the sprays providing the tangential force required to rotate the

arms.—A. Anable. *Contract Rec. & Eng. Rev.*, 46, 41:1164-5 (Oct. 12), 1932. From *Pub. Health Eng. Abstr.*, 2-4-33. Abstr. Rudolph E. Thompson.

Sterilization of Dairy Containers and Utensils With Dry Heat Approved—The Commissioner of Health has accepted dry heat sterilization as an approved method of sterilizing milk containers and utensils. If this procedure is used, containers and utensils should be placed in the sterilizing box or cabinet in a moist condition. The temperature in the sterilizer should then be raised to 200° F. and maintained at that point for 10 minutes. The containers and utensils may then be removed, and another set placed in the cabinet. After exposure to 200° F. for 10 minutes, the heat should be shut off and this second set allowed to cool while in the sterilizer.

The time necessary either (1) to heat the utensils to the specified temperature, or (2) to cool them from that point in the sterilizer, is considered essential as well as 10 minutes' exposure as outlined above.

A careful study of dry heat sterilization was made by the New York State Agricultural Experiment Station at Geneva, N. Y. The results are reported in *Bulletin No. 612* issued by that Station. It is recommended that health officers procure a copy of this publication in order that they may become familiar with the details of this procedure. Such knowledge is necessary to insure proper supervision of dry heat sterilization of dairy containers and utensils.—Anon. *Health News*, New York State Dept. of Health, 9, 38:153 (Sept. 19), 1932.

A Waterborne Epidemic of Typhoid Fever—A severe outbreak of typhoid at the village of Ecclefechan, Dumfriesshire, in the summer of 1930 after heavy rains was traced to the water supply. Spring water is piped to two tanks and storm water carried past the lower of these by a field drain. Surface openings in the drain and faulty joints in the pipe where this crossed the drain enabled contamination, deposited at any part of the valley, to enter the spring water. Identification of a typhoid carrier in the water-collecting area confirmed this supposition. Measures taken included refilling of the tank with chlorinated water, chlorination of the supply and overhauling of the pipe line.—J. Ritchie and E. Armstrong. *J. Hyg.*, 32:417, 1932. From *Summary of Current Lit.*, Water Pollution Research, VI, 4:111 (Apr.), 1933.

A Tour of Hamburg—A description is given of the problems of water supply and sewage disposal in Hamburg, where a population of $1\frac{1}{4}$

millions has a state territory of only 415 sq. kn. of which a quarter is under water. Reference is made to the many publications on Hamburg's water supply. This is drawn mainly from artificial ground water works at Curslack which are shortly to be supplemented by new works at Grossensee and Grosshansdorf. At present a quarter of the supply is drawn from the Elbe, treated in settling tanks with coagulation and prechlorination, filtered through open sand filters and chlorinated. Although of excellent bacteriological and chemical quality, this water has many disadvantages such as a high salt content, variable temperature, tastes from organic wastes, etc. It is hoped in time to replace Elbe water by ground water.

Two sewage treatment plants at Langenhorn and Elmshorn are described. Both of these have "Dywidag" tanks and activated sludge plants. The sewage of Elmshorn contains in a total flow of about 6,000 c.m. about 2,000 c.m. per day of tannery wastes and 2,500 c.m. of other trade wastes. As a result of successful treatment of sewage and tannery wastes in the present plan, a large scale plant, comprising sand trap, screens, "Dywidag" tanks and activated sludge tanks, is under construction. The whole sewage of Hamburg itself, after passing through a coarse screen and a sand trap, is discharged into the Elbe 8.5 km. below the intake of the water works.—K. v. Vagedes, *Kl. Mitt. Ver. fur Wasser-Boden- u. Lufthyg.*, 8:217, 1932. From *Summary of Current Lit.*, Water Pollution Research, VI, 4:113 (Apr.), 1933.

Progress in the Construction of Small Iron Removal Plants—Two forms of iron removal plants suitable for small supplies are described. In the first the water is pumped by a hand pump to the top of a tower in which

is placed a suitable depth of filter material with a water storage space and outlet tap at the bottom of the tower. The second form of plant is suitable for attachment to a water pipe. The water flows on to a coke layer and passes, in finely distributed form, to a bed of sand, gravel and charcoal. Iron sludge can be removed from this bed by back-washing. Both plants can be adapted for the removal of small quantities of manganese or can be used as mechanical filters for turbid water.—W. E. v. Gronow, *Gesund. Ing.*, 55: 495, 1932. From *Summary of Current Lit.*, Water Pollution Research, VI, 4:116 (Apr.), 1933.

Killing Pond Weeds in Storage Reservoirs—Pond weeds in a small open storage reservoir less than 1 acre in area at Scranton, Pa., were killed by application of about 1,500 lb. of copper sulphate to the bottom after draining and removal of the mud by scraping. Their reappearance the following year led to a further treatment with 2,000 lb. of copper sulphate which has, it is believed, killed off most of the weeds. The whole work cost \$300. A heavy dose of copper sulphate was necessary to penetrate the mud and kill the roots.—G. R. Taylor, *Am. City*, 47, 4:7, 1932. From *Summary of Current Lit.*, Water Poll. Research, VI, 4:119 (Apr.), 1933.

Ipswich Sewage Disposal—After a brief description of the previous sewerage and sewage disposal systems of Ipswich, an account is given of the new high level sewerage system and disposal works. The population of Ipswich is about 87,000 and the daily dry weather sewage flow about 1 mil. gal.

Mechanically raked screens are inserted in both the new high level and the old low level intercepting sewers. Screenings fall into troughs and are washed by sludge from the sludge

tanks to a stereophagus pump which breaks up the screenings and lifts them to the sludge tank. By using sludge for carriage of screenings the extra bulk added to the sludge tanks is limited to the screenings only. Low-level sewage is then pumped to mix with high-level sewage and the whole is passed through mechanically cleaned detritus tanks at a velocity of about 1 ft. per sec. and with a retention period of about 1 min.

Hopper type horizontal flow settling tanks provide 12 hours' retention for 6 times dry weather flow (the estimated dry weather flow 40 years hence). The effluent is discharged into the river and sludge is carried out to sea.—*Surveyor*, 82:547, 1932. From *Summary of Current Lit.*, Water Pollution Research, VI, 5:128 (Apr.), 1933.

Gas Production and Utilization in the Municipal Sewage Works of Blankenburg (Harz)—The Blankenburg sewage works, for a population of 12,000, comprise settling tanks, digestion tank, trickling filters and humus tanks. The construction of the digestion tank, a cylindrical tank divided into two communicating sections, with a submerged cover and two gas collecting domes, is described. The sludge is heated by hot water coils and, although the sludge is not stirred to give even heating, the effect on gas production has been satisfactory—80–100 c.m. of gas are obtained daily.

The gas is used for heating the water for the digestion tank, for a gas engine and dynamo which generate sufficient electricity to supply the power and light requirements of the works, and for heating offices and houses in the works. As these uses do not exhaust the gas, it is proposed to introduce a plant for circulating the sludge in the digestion tank.—*Weidlich. Gesund. Ing.*, 55:485, 1932. From *Summary of Current Lit.*, Water Pollution Research, VI, 4:129 (Apr.), 1933.

INDUSTRIAL HYGIENE

Air Cooling by Conduction and Convection—This article describes the method of calibration of the coolometer as an anaemometer. An expression for the determination of velocities of air over 100' per minute is developed from the experiment; no exact expression for velocities below 100' per minute could be obtained.

The authors suggest that the effect of radiation may be measured by using this instrument first as a polished body and then coating it with lamp black for use as a black body.—Walter S. Weeks and Fred G. DeBerry, *J. Indust. Hyg.*, XV, 1:34-39. L. G.

Air Conditioning with Relation to Comfort, Health and Efficiency—The first part of this article deals with air conditioning experiences in a home in Columbus, Ohio, which was studied over a period of 10 years by the author. Conditions, particularly those during the winter seasons, are described. A careful record of disabilities of an experimental group consisting of the family of 5 persons showed a better than average health record. The author believes that this tends to support the belief that the state of nutrition (resistance) and not "bad air" determines respiratory affections and their complications.

The second part of this article considers the various aspects of schoolroom ventilation. The chief complaint in uncomfortable rooms is not ventilation but overheating, to which stuffiness and odors bear a direct relation. The author feels that education in air-conditioning principles and purposes, and¹ in optimum air temperatures, is essential.—Emery R. Hayhurst, *J. Indust. Hyg.*, XV, 2:98-115. L. G.

The Influence of Respiration and Transpiration on Ionic Content of Air of Occupied Rooms—A series of experiments is described dealing with the number of small ions affected by respiration and transpiration, and the effect on the ionic content of occupied and unoccupied rooms, of (a) no ventilation, (b) window ventilation, and (c) mechanical ventilation.

In rooms there was a marked decrease in the number of both positive and negative ions with occupancy. These ions increased in number as the occupants of the room departed. The loss of ions in occupied rooms appears to be largely due to adsorption by clothing, and to a small extent to respiration and transpiration through the skin. Expired air was found to be devoid of ions.

The minimum supply of outdoor air required to maintain normal ionic content in a crowded room was found to be prohibitively high—160 cu. ft. per person per minute. A supply of 30 cu. ft. per person per minute did not appreciably increase the ionic content of the air.

No evidence is presented to prove or disprove the prevailing belief that ionization might be a factor in ventilation.—C. P. Yaglou, L. Claribel Benjamin and E. Allen Brandt, *J. Indust. Hyg.*, XV, 1:8-17, 1933. L. G.

Further Research on the Production of Carbon Monoxide from Paint in Sealed Compartments—Previous investigations have shown that the paint used on the walls of sealed ship compartments gives off carbon monoxide. The present study was inaugurated to determine the quantitative aspects of the problem using vari-

ous types of paint. The materials investigated were iron oxide paint, red lead paint, aluminum paint, bituminous compositions, and grease paints. The experiments indicated that any composition containing linseed oil, in a confined space, not only gives rise to dangerous concentrations of carbon monoxide but will also, through absorption of oxygen during drying, produce an atmosphere markedly, and in some cases almost completely, deficient in oxygen.

Biological experiments with mice were also carried out to determine the effect of the gaseous content of the sealed painted compartments.—R. C. Frederick, S. F. Dudley, F. G. Edwards, *J. Indust. Hyg.*, XV, 1:1-7, 1933.

L. G.

Report of Advisory Committee on Employment of Minors in Hazardous Occupations—This is the report of the special committee appointed to follow up the White House Conference on Child Health and Protection in coöperation with the Children's Bureau. The committee met in Washington May 24-26, 1932, and its conclusions, after various drafts, are reported herewith. It is recognized that these recommendations may require revision from time to time, in which case the help of the committee will again be sought.

The Report considers first specific recommendations for minors under 18, *i.e.*, their prohibition in occupations involving (1) general mechanical hazards, of which 28 are listed, (2) mechanical hazards with specified machines, of which 34 are listed, and (3) occupations involving various health hazards. This latter group lists exposures to heavy chemicals, unsterilized hides or animal hairs, various physical conditions (named), certain dusts in injurious quantities, 16 specified poisons, and excessive exposure to 11 other poisons with a provision in

each poison list for "other substances having similar injurious properties."

Children under 16 should not be permitted to work in any employment, except when schools are not in session and then in a carefully restricted list of occupations (not specified).

Among the general recommendations are power to be given to state labor boards to determine what are dangerous and injurious occupations, to revise from time to time the rules that have been laid down, the enforcement of laws and rulings, the matter of extra compensation, machinery or other apparatus in educational and other institutions, conditions of work (which are injurious), etc.—*Month. Labor Rev.*, 35, 6:1315-1322 (Dec.), 1932. E. R. H.

Third Report of the Miners' Nystagmus Committee—Two previous reports upon this subject appeared in 1922 and 1923, as Nos. 65 and 80 in this series. The principal finding of the earlier committee was that the nystagmus was caused by an insufficiency of light reaching the eye of the miner while at work, and the present committee reaffirms this finding in the strongest terms.

The criterion of incapacity is not easily determined. Mere oscillation of the eyeballs is not a trustworthy test of incapacity, since many men with this symptom are working efficiently. On the other hand, the absence of this symptom, in the presence of symptoms of a nervous or psychological kind, is not sufficient proof of fitness for work. It is the opinion of the committee that the true significance of the various symptoms can be elucidated only by medical men with the requisite training.

An appendix, by Professor Culpin, gives the findings of an experimental investigation of 36 cases of miners' nystagmus, and another appendix, by T. L. Llewellyn, the relation of changes in illumination to the incidence of

nystagmus.—Medical Research Council, *Special Report Series No. 176*, 1932, 36 pp. British Library of Information, 270 Madison Ave., New York, price 9d. net. E. R. H.

The Incidence of Color Blindness among Races—Color blindness for white males showed an incidence of 8 per cent and for females 1 per cent. The incidence among all other races (Indians, Mexicans, Spanish-Americans and Negroes) was very much less, although higher among males than females. The incidence among white male Jews was 4 per cent, while for white female Jews it was zero. Geographical classification apparently has no influence in the matter of color blindness.—Thomas R. Garth, *Science*, 1996:333-334 (Mar. 31), 1933.

E. R. H.

Speed of Visual Perception—Author's summary and conclusions:

1. A time factor should be incorporated in our visual acuity examinations.
2. 0.5 second observation time is a good standard unit for each eye.
3. Visual speed by daylight is decidedly faster than by artificial illumination.
4. Visual speed ranged from 0.5 second per letter to 0.01 second among candidates examined.
5. A few candidates with a slow color perception apparently compensated with rapid form perception.
6. Color perception is not diminished as rapidly as form perception by shortening the period of observation.
7. Form speed of perception for both eyes is twice that of monocular vision.—

P. Richmond, E. C. Ebert, *U. S. Nav. Med. Bull.* 31, 2:150-151 (Apr.), 1933.

E. R. H.

Influence of Industry on Public Health—After reciting the influence of lead, industrial cancer, anthrax, dust, nystagmus, dermatitis, and accidents in relation to public health, the author stresses the value of the industrial periodic examination of workers to the

public in general. The increasing incidence of tuberculosis among females is ascribed to fatigue and its consequences, not produced by employment but by the efforts spent in relaxation. "Speaking generally, it is not my view that industry as carried out in factories or workshops adversely affects health; rather do I think that in many respects it exercises a beneficial effect not only on those actively engaged in it but also indirectly on those not so employed."—J. C. Bridge, *Lancet*, 5718:697-698 (Apr. 1.), 1933. E. R. H.

Control of the Silicosis Hazard in the Hard Rock Industries. IV. Application of the Kelley Trap to Underground Drilling Operations—This report extends the investigation of the Kelley dust trap to include its application to underground operations as well as in open excavation work. The results of the test indicate that for horizontal and down drilling, an air flow of 200 cu. ft. per minute through the hood is necessary to keep the dust concentration at the breathing zone to below 10 million particles per cu. ft. of air.

Dust counts obtained during wet drilling were higher than those given by the blower type drill equipped with an exhaust hood. The speed of drilling was found to be 40 per cent higher and the overall footage 8 to 26 per cent higher in the case of the blower type drill as compared to the American and South African type wet drills.

The need for efficient and compact dust disposal plants for underground work is pointed out.—Theodore Hatch, J. W. Fehnel, Henry Warren, and George S. Kelley, *J. Indust. Hyg.*, XV, 1:41-56, 1933. L. G.

A Study of 78 Workers Exposed to Inhalation of Cryolite Dust—In this study 78 workers engaged in the crushing and grading of cryolite

(aluminum-sodium fluoride) were examined and X-rayed. The mineral contained approximately 3 per cent of quartz. All of the workers studied were exposed for a period of 2 years and over; 22 had been engaged for more than 10 years. Of the 78 workers studied 22 were negative and 17 were classified as probably negative; 25 were classified as having probable second stage silicosis or second stage silicosis of mild or marked degree. Two-thirds of the workers engaged over 10 years had second stage silicosis. There did not seem to be an excess of pulmonary tuberculosis among the workers but 4 cases of pulmonary tuberculosis were discovered and three of these occurred among persons having no silicosis. No dust counts are presented in this report.—Sk. V. Gudjonsson, *J. Indust. Hyg.*, XV, 1:27-33, 1933. L. G.

Studies in Dust Retention.
IV. Dust Retained by the Tracheotomized Cats—This article describes experiments in dust retention by tracheotomized cats by exposing them to limestone dust (particle size averaging less than 1 micron) and magnesium oxide dust (average particle size less than 0.5 micron) of varying concentrations in a large gas-tight cabinet. The rate and depth of breathing of the cats were varied and the effects noted.

Five to fifteen experiments were performed on each animal, the period of dust exposure varying between 4 to 30 minutes depending upon dust concentrations and breathing rates. The average exposure was about 10 minutes.

The results showed that the retention of limestone dust increased rapidly with concentration while that of magnesium

oxide increased but slightly with concentration.

Macroscopic examination of the lungs at autopsy indicated that prolonged dusting with magnesium oxide caused dusky areas of hyperemia in the independent portions of the lungs.—Tomoyoshi Ishikawa and Philip Drinker, *J. Indust. Hyg.*, XV, 2:57-65, 1933. L. G.

Effect of Certain Silicate Dusts on Lungs—This paper presents the results of a study on the pulmonary effects of the inhalation of tremolite talc, red slate and a greenish slate. All of these substances contained approximately 60 per cent silicate; the tremolite talc contained no quartz, green slate but a trace and the red slate 3 per cent of quartz. The workers were engaged in the crushing and grading of the material.

The dust count in the tremolite talc industry was approximately 1,400 million particles per cu. ft. of air for miners and 52 millions for millers. Among the slate workers the millers were exposed to about 700 million particles per cu. ft. of air and other workmen to about 15 million such particles.

It was found as the result of this study that the workers exposed as noted above became afflicted with a fine, diffuse bilateral pulmonary fibrosis which apparently did not yield disability.

Two cases of third stage pneumoconiosis were found in the slate workers but none were found in the tremolite talc group in spite of the fact that over 20 men were engaged for more than 15 years.—Waldemar C. Dreessen, *J. Indust. Hyg.*, XV, 2:66-78, 1933. L. G.

FOOD AND NUTRITION

The Winesap Apple as a Source of Vitamin C—Since Winesap is the leading variety of apple commercially grown in the United States, this variety was used for the experiment. Fruit from trees not fertilized and from trees receiving applications of complete fertilizers were selected. The feeding experiments were conducted between November 3 and February 15.

Thirty-seven guinea pigs weighing approximately 294 gm. were used. A basal vitamin-C-free ration consisted of oats, baked skim-milk powder, butter-fat, sodium chloride, and cod liver oil. Six animals were used as positive controls and received orange juice while 6 animals as negative controls were given the basal ration only. Eleven animals were fed 5 gm. of apple, 13 were fed 10 gm., and 2 were fed 15 gm. daily, 6 days per week. Records were kept as to the animals receiving apples from fertilized and unfertilized trees. The experimental periods were 90 and 70 days' duration and the animals were weighed on alternate days and observed for symptoms of lameness, soreness, and enlargements of wrists.

The positive groups made weight gains, survived the experimental period, and autopsy exhibited no symptoms of scurvy, while the negative control group showed severe scurvy symptoms, weight losses and an average survival period of 26 days.

The 5 gm. level of apple feedings did not furnish adequate protection from vitamin C deficiency. This was particularly true when the apples fed were from trees not receiving complete fertilizer. The 10 and 15 gm. levels of apple feeding fully protected the animals from scurvy whether the fruits

were from trees fertilized or non-fertilized. The animals survived the experimental periods and made small weight gains.—Myra T. Potter, *J. Home Econ.*, 25:52 (Jan.), 1933.

The Vitamin C Content of the Winesap Apple as Influenced by Fertilizers—This is the report of a more detailed study made to find the relative influence of the application of fertilizers upon the Winesap apple as a source of vitamin C. The fruit was obtained from trees 20 years old. The fertilized trees during 1928 to 1931, inclusive, received annual applications per tree of complete fertilizer—5.7 lb. of an equal mixture of ammonium sulphate and sodium nitrate, 11.7 lb. of superphosphate, and 3.9 lb. of a mixture of equal parts of muriate of potash and sulphate of potash. The check trees received no fertilizer applications. A basal vitamin-C-free ration was fed. Forty-two guinea pigs, weighing 325 gm. each were grouped as follows:

Six animals received the basal ration plus orange juice; 6 animals received the basal ration only; 15 animals received the basal ration plus 5 gm. of fertilized Winesaps; and 15 received the basal ration and 5 gm. of non-fertilized Winesap apples. The apple feedings were made daily, 6 days a week. The animals were observed daily for lameness, soreness, and enlargement of wrists, and were weighed on alternate days. In 1930-1931, the experimental period was 70-90 days and in 1931-1932 it was 56 days.

It was found that 60 per cent of the animals receiving apples from fertilized trees were protected or developed only mild scurvy, while not one of the

animals fed apples from non-fertilized trees was protected, and 80 per cent developed moderate to very severe scurvy.—Myra T. Potter and E. L. Overholser, *J. Agri. Res.*, 46:367 (Feb. 15), 1933.

Vitamin A in Six Varieties of Frozen Cherries—In this investigation, frozen cherries of sour, sweet, and hybrid types were used. Sound fruit was washed, dried, packed in small glass jars, and placed in a refrigerating room at a temperature of -10° C. The fruit was held from 6 to 10 months and individual feedings were weighed and fed while still frozen. Rats between 21 and 28 days of age and weighing 44 gm. were placed on a vitamin-A-free diet, consisting of corn-starch, casein, Osborne and Mendel salt mixture, powdered dry yeast and sodium chloride. Four different levels—0.125, 0.250, 0.375 and 0.500 gm.—of cherry portions were fed daily. In this study it was found that the Lambert, the Bing, and the Deacon, the black sweet varieties, were relatively lower in vitamin A than the Royal Ann, the Late Duke, and the Montmorency. The Montmorency was the richest source of vitamin A. Of the sweet varieties, the Royal Ann ranked highest as a source of vitamin A. The cherry compares favorably with other fruits in vitamin A potency.—Myra T. Potter and Mabel A. Dickson, *J. Home Econ.*, 25:47 (Jan.); 1933.

Study of the Iodine Content of the New Zealand Seaweed and Fishes—The authors have recorded the iodine content in a number of seaweeds and fishes. Seaweeds on the Pacific Coast of Otago are comparable to similar species on the Pacific Coast of British Columbia. In one specie, *Cystophora retroflexa*, over 0.1 per cent of iodine is contained, and 70 to 80 per cent of this appears to be in the

inorganic or loosely bound form. Analytical methods are given for the determination of iodine and for the detection of di-iodotyrosine which has been identified.

Experiments on rabbits were performed to note the change in iodine content of the blood during anesthesia. These experiments suggest that only in the case of inorganic iodine will there be a redistribution of iodine between tissues and blood serum under the influence of anesthetics. In the case of rabbits, New Zealand cabbage is stated to possess goitrogenous properties to a smaller degree than American cabbage.—C. E. Hercus and H. A. Aitken, *Brit. J. Hyg.*, 33:55 (Jan.), 1933.

Effect of Irradiated Ergosterol After the Removal of the Parathyroid Glands from Rats—These experiments were made to test the efficacy of moderately large doses of irradiated ergosterol given over a long period of time in preventing growth differences between normal rats and those from which the parathyroids have been removed. Two series of animals were studied—one in which the parathyroids were removed at 50 days of age and in the other at 75 days of age. The parathyroidectomized rats which were fed on the Steenbock stock ration without the milk supplement until 150 days of age showed no change in water, lipid, or ash content of their femora or humeri as compared to the normal control. The blood calcium of the animals was somewhat below normal at the end of the experiment and 8 of 21 rats so treated showed weakness, stiffness of the rear legs, tetany, and decreased rate of growth, and in some instances actual loss of weight. Three of these animals died during the experimental period.

Another series of parathyroidectomized rats, which received irradiated ergosterol solution (1000 D) incorpo-

rated into the ration at a 1 per cent level, failed to maintain normal concentration of blood calcium, and 2 of the 21 animals showed loss of weight, general weakness, and stiffness of the rear legs, but no tetany. None of these animals died during the experiment.—Dorothy W. Asher and James H. Jones, *J. Biol. Chem.*, 100:333 (Mar.), 1933.

The Fate of Tartaric Acid in the Human Body—The fate of tartaric acid both in experimental animals and in the human body has been the subject of a great many studies and the view has generally been that tartaric acid is

oxidized in the body. The experiments reported here indicate that tartaric acid (sodium tartrate) is not utilized in the human body, neither is it transformed. When injected intramuscularly, tartaric acid reappeared almost quantitatively in the urine within 10 hours, the major portion being excreted within the first 4 hours. When taken by mouth, only about 20 per cent is eliminated in the urine, but from previous work reported it is probable that this portion of tartaric acid is destroyed in the intestinal tract by bacterial action.—Philip Finkle, *J. Biol. Chem.*, 100:349 (Mar.), 1933.

EDUCATION AND PUBLICITY*

AN absence from the city made it impossible to prepare the usual quota of copy for this department. This offered an opportunity for submitting the article which follows—an attempt to picture the status and some of the relationships of popular health education as practised in the United States and Canada.

Readers are invited and urged to send criticism or correction of facts and ideas, and to point out inadequacies in the presentation. Enlargement of some of the points made would be welcome.

HEALTH Education for Adults and Young People Not in School or College—is directed toward three diverse objectives: (1) improvement of the habits of individuals which affect their health, (2) improvement of family and community conditions which have such an effect, and (3) creation of such understanding of official and voluntary health agencies by the public as will insure the support of their policies and the maintenance of their activities. For the subject of health

education related primarily to the school child see Health Education for Children (in *Social Work Year Book*).

Health education in the classroom may be and usually is more continuous, systematic, and progressive than is possible elsewhere. But popular health education bears part of the responsibility for the school child through its service in teaching the parent and the community. The school activities, moreover, are supplemented by the health education programs, of varying effectiveness, provided by numerous agencies concerned with the interests of boys, girls, and young people. Much is accomplished by practising phy-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ernst G. Reutzahn, 139 East 22d St., New York, N. Y.

sicians and nurses in homes and at clinics, and by other professional visitors to those in need—social case workers, dietitians, or visiting housekeepers, and somewhat systematic instruction is also given in mothers' conferences or classes. The threefold objective must usually be sought, however, through less direct channels.

Types of Participating Agencies—Responsibility for general and specialized programs of health education is widely distributed, national, state, and local agencies, both public and private, sharing in the work. To some extent county and state medical societies carry on active campaigns of education, and the American Medical Association has its capably directed Bureau of Health Education, and *Hygeia*, its popular health magazine. Many mediums are used and coöperative relationships are established for the purpose with many non-health organizations. For several years the Chamber of Commerce of the United States has offered a group of awards annually to cities for their public health work, and effective health education is given recognition in these awards. The General Federation of Women's Clubs and various state federations have promoted campaigns for better personal and community health, and all national and social agencies in the character-building group have health education programs. In fact, almost any of the many types of organizations into which men, women, and young people group themselves may undertake work in this field. Sometimes they are stimulated by their state or national organizations. Frequently an energetic individual, aroused by his experience with some health agency, organizes one or more health talks, the showing of motion pictures, or the distribution of printed matter.

Various types of social agencies, furthermore, have included health edu-

cation with individuals, groups, and the community as an essential means for carrying out their primary purposes. For example, much of the earlier program against tuberculosis was organized in family welfare societies. Business houses, trade groups, and life insurance companies issue some of the best prepared and most attractive health education material that is published. On the other hand, much unsound advice and some that is extremely vicious and disastrous is given by a few firms which use a health appeal in their advertising. The National Better Business Bureau supplies newspapers with information about the fraudulent health claims of advertisers, and the American Medical Association, the Information Bureau of the New York Academy of Medicine, and similar agencies are increasingly called upon by publishers to check the validity of such claims.

Difficulties Faced, and Means Employed—Popular health education faces wide differences in the intelligence of its audience and in the needs or resources of the individuals who constitute that audience. Moreover, a real motivating interest in the subject is lacking, as witness the slow response to the diphtheria prevention campaigns in spite of parental love as an incentive. Though the disease is easily preventable to almost 100 per cent, and adequate provision is made for free treatment where needed. It nevertheless requires intensive campaigns of education, supplemented by aggressive organized efforts, to have children taken to physicians or clinics for inoculation. The patent medicine bill of the United States, according to *Business Week*, was \$472,000,000 in 1929. The total annual expenditure for public health by governments and philanthropy, as given in the final report of the Committee on the Costs of Medical Care, is \$121,000,000.

In health education programs prac-

tically all known methods for getting attention, spreading information, and stimulating action are utilized. The diversity of need implied by the three-fold objective gives opportunity for a wide range of method. The newspapers have served public health education more than any other group of coöperating agencies. They have been the chief reliance of many health departments and many voluntary health agencies, and in numerous times of emergency they have been the main channel for reaching the public.

Next to the newspaper the radio continues as the obvious channel for community-wide efforts, plus the intensive campaign, promoted locally or nationally. Unfortunately there is little check upon what the unscrupulous may urge or claim through radio broadcasts. The early diagnosis campaigns of the tuberculosis associations are nationally promoted, as are the campaigns for promoting safety. See *Safety Education and Tuberculosis*. Health Weeks in various forms are frequently organized locally, and sometimes, as in Illinois, on a state-wide basis. Epidemics and similar emergency conditions usually lead to intensive campaigns directed toward the general public. But there is a growing trend toward planned year-round programs, based on studies of needs and resources. The Public Health Education Section of the American Public Health Association is contributing to this end. On the whole there has not been significant progress in frankly facing the complex situation and working out programs of progressive, cumulative presentation which might make headway in the midst of the competition.

Gratifying progress has been made, however—particularly within the past ten years—in the effectiveness of methods and materials used by health agencies. More and more they have learned to employ the arts and skills

which result in the preparation of readable and effective printed matter. The spoken word is also used more skilfully, and other forms are better prepared and more effectively used. In this development the contributions of modern psychology have been drawn upon, but many workers have been too overwhelmed by the mass of their work to give much thought to the way of doing it.

Evaluation, Leadership, and Training—The weakest point in health educational work today is the lack of evidence as to results, or of means for testing the effectiveness of methods and materials. Two or three carefully controlled tests have been made in the social hygiene field, as reported in publications of the American Social Hygiene Association (*infra cit.*), but adequate and convincing evaluation of methods and results awaits the time when money and personnel are at hand for tests which shall extend over a period of years.

An important unsolved problem is that of leadership for coördinating the many varied educational projects. Nationally, in states, and locally, groups of general and specialized health agencies are spreading health information with little or no coördination of effort. Logically, leadership should rest with governmental agencies, and in a few instances health departments have capably accepted the responsibility. Hopeful developments also, in a few cities, are health councils in which both public and private health agencies of a community unite in organizing a gradually inter-related program of health service, including popular health education. See *Health Councils*.

A notable event in this field in 1932 was the publication of *Community Health Organization* (*infra cit.*) with the fullest presentation yet made of the scope and nature of an effective health education program for city health de-

partments. This book supplies what is possibly the first authoritative recognition of the fact that adequate salaries are needed for health education specialists in public health departments.

At present only a small proportion of health agencies employ staff members who are experienced in using the several technics required for the various forms of public health education. Training opportunities are few. Most of the professional public health training schools recognize health education only to the extent of a session or two in a broad course on public health administration. In the institutes for workers in tuberculosis conducted by the National Tuberculosis Association several sessions are devoted to forms of publicity or health education. At Washington, in October, 1932, the Public Health Education Section of the American Public Health Association enrolled 108 students in a 3-day institute. That section has been a vital factor in improving standards and in-

creasing understanding in the field. Its membership includes persons concerned professionally with public health education, and also health educators in schools and colleges who associate themselves with the public health field. "Education and Publicity," a department of *American Journal of Public Health*, has been useful as a clearing house of ideas and information.

The Social Work Publicity Council serves a large group in this field, particularly persons concerned with the technic of preparing printed and other materials for educational purposes. Of the awards made in 1932 for outstanding examples of publicity, 6 went to health agencies. Though health association conventions and social work conferences provide one of the best available channels for educating executives and staff workers on the job, there is a disappointing lack of consideration of adult health education topics on their programs.—Ewart G. Routzahn, *Social Work Year Book*. Russell Sage Foundation, New York, N. Y., 1933.

PUBLIC HEALTH NURSING*

Public Health Nurses—Ratios to Population in Two States—

Wisconsin—A.P.H.A. Standard applied to Wisconsin—1 public health nurse to 4,400 people. Wisconsin ratio (exclusive of nurses employed by insurance companies and industrial concerns)—1 public health nurse to 8,750 people. Wisconsin ratio (exclusive of Milwaukee)—1 public health nurse to 10,089 people.

A.P.H.A. city of 100,000 population standard—1 public health nurse to

3,200 people. Milwaukee City—1 public health nurse to 4,800 people.

A.P.H.A. standard for cities of 50,000 where morbidity service is given—1 public health nurse to 2,800 people. Wisconsin cities offering preventive and morbidity service—1 public health nurse to 3,630 people.

A.P.H.A. ratio for rural nursing service—1 public health nurse to 6,000 people. Wisconsin ratio for rural nursing service—1 public health nurse to 17,800 people.—*Pub. Health Nurses' Bull.*, Bureau of Public Health Nursing, Wisconsin State Board of Health, 11 (Apr.), 1933.

Indiana—(Visiting Nurses employed

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

by insurance companies, and industrial nurses are counted in with other public health nurses in computing the ratio of nurses to population.)

There is 1 public health nurse to every 8,601 of the general population of the state; 1 public health nurse to every 5,780 of the urban population, and 1 to every 30,496 of the rural population.

Bon Voyage for American Nurses!—American nurses have been saving up their pennies to attend the Congress of the International Council of Nurses to be held in Paris, France, July 9 to 13, and in Brussels, Belgium, July 15 to 19. The last Congress was held in Montreal, Canada, in 1929.

The 23 countries whose nursing associations are affiliated with the I. C. N. are: Belgium, Brazil, Bulgaria, Canada, China, Cuba, Denmark, Finland, France, Germany, Great Britain, Greece, Holland, India, Irish Free State, New Zealand, Norway, Philippine Islands, Poland, South Africa, United States, and Yugoslavia.

Mlle. L. Chaptal of Paris is President of the I. C. N. and Clara D. Noyes of the American Red Cross Nursing Service is First Vice-President.

American Nurses scheduled to be on the program at the Congress are Effie Taylor, Nellie X. Hawkinson, Edith Potts, Stella Goostray, Mary Roberts, Elnora Thomson, Adda Eldredge, Laura Logan, and Shirley Titus.

Thomas Cook and Son—Wagon-Lits, Inc., are the official transportation agents for the Congress. Rates are \$123–\$139 for round-trip third class accommodations, to \$236–\$416 for round-trip first class accommodations, with tourist and cabin rates in proportion.

Many attractive tours are being planned through Europe both before and after the Congress.

Florence M. Johnson, 315 Lexing-

ton Avenue, New York, is the Chairman for the American Nurses' Association Transportation Committee of the I. C. N. and would like to have all nurses planning to attend the Congress, irrespective of the routes or tours they have chosen, notify her, as the French and Belgian nurses are anxious to know as soon as possible how many nurses to prepare for.—*News, Am. J. Nurs.*, XXXIII, 3:278–282 (Mar.), 1933. *Ibid*, XXXIII, 4:386 (Apr.), 1933.

An Opportunity for Public Health Nurses in the Middle West—The American Child Health Association announces that its seventh Health Education Conference will be held at Ann Arbor this year from June 20 to 24 at the invitation of the University of Michigan Summer Session.

Experiences during the last 3 years in all phases of the school health program will be used in the discussions with the expectation of arriving at helpful conclusions for present situations.

Dr. John M. Sundwall of the University of Michigan is general chairman and he and his local committee are making all housing arrangements. Efforts are being made to reduce the living cost to a minimum.

Many public health nurses will be glad to spend this week at Ann Arbor and freshen up on health education problems by discussion and contact with leaders in that field. Nurses planning to attend summer school will have time in most cases to attend this conference before they begin classes.

While discussions in this conference will center around the school child and be of most vital interest, perhaps, to public health nurses working with school children, still all public health nurses are teachers and engaged in health education work and it may be that visiting nurses and infant welfare nurses will learn even more from this conference than school nurses.

BOOKS AND REPORTS

Recent Social Trends in the United States—*Report of the President's Research Committee on Social Trends in the United States, with a Foreword by Herbert Hoover, 2 Vols. New York: McGraw-Hill, 1933. 1568 pp. Price \$10.00.*

In December, 1929, President Hoover appointed a group of eminent scientists to undertake a national survey of social trends in the United States. This report is the result. In view of the nature of its task, President Hoover observes in the foreword that the committee places emphasis on elements of instability rather than stability in our social structure. A summary of the findings is presented in 29 chapters prepared by experts, preceded by a comprehensive statement which represents the collective judgment of the committee regarding the material and its implications.

Modern life is everywhere complicated, but especially so in the United States, where immigration from many lands, rapid mobility within the country itself, the lack of established classes or castes to act as a brake on social changes, the tendency to seize upon new types of machines, rich natural resources, and vast driving power, have hurried us dizzily away from the days of the frontier into a whirl of modernisms which almost passes belief.

The committee has endeavored to portray the bewildering confusion of the problems as the members uncovered the situation, and in contrast with certain national committees, has not attempted to make recommendations regarding future organization except in a general manner.

Along with amazing mobility and complexity, note is made of a marked indifference to the interrelation among the parts of our huge social system.

The outstanding problem might be stated as that of bringing about a realization of the interdependence of the factors of our complicated social structure, and of interrelating the advancing sections of our forward movement so that agriculture, labor, industry, government, education, religion and science may develop a higher degree of coördination in the next phase of national growth.

One of the many values of this report is the assembly and interrelation of the many factors and elements in the social life of America.

Of the great social organizations, the economic and governmental are growing rapidly, but two other historic organizations, the church and the family, have declined in social significance, although not in human values. It is believed that many of the problems of society occur because of the changing rôles of these four major social institutions. The importance of viewing social situations as a whole is emphasized.

Effective coördination of the factors of our evolving society mean, where possible and desirable, slowing up the changes which occur too rapidly and speeding up the changes which lag. The committee does not believe in a moratorium upon research in physical science and invention, such as has sometimes been proposed. On the contrary, it holds that social invention has to be stimulated to keep pace with mechanical invention. What seems a welter of confusion may thus be brought more closely into relationship with the other parts of the national structure, with whatever implications this may hold for ideals and institutions.

The problems affected by social change are considered under three groups: man's physical heritage, biological heritage, and social heritage—or cultural environment called civilization.

The declining rate of population growth and its significance, the distribution and quality of population, are con-

sidered in detail. Relative to practical possibilities of improving a people by conscious selection, it is suggested that in time higher eugenic ideals may emerge from research on this question; but more immediately urgent is the need of preventing individuals with undesired inheritable traits from having offspring.

The amelioration of conditions of poverty, disease, and crime, and other distressing problems occasioned by inequalities of life, such as ignorance, physical defects, family desertion, and unprotected children, is considered a major objective involving technics of modern social science and public welfare. While social insurance does not remove the cause of dependency, it may stimulate preventive measures.

The indications are that the United States in the near future will have to face the problem of providing more certainly and systematically for these ills which at all times, and particularly in periods of depression, have come to be a major task of public and private social work.

The practice of medicine is in a state of transition which is perhaps analogous to the state of industry during the early period of mechanization. There is a marked survival of traditional, individualistic practice, to which many physicians cling as did the early handicraftsmen seeing their independence and their creative skill threatened by the machine.

The serious dearth of physicians in rural districts, the rapid growth of medicine, and the place of the hospital and clinic are discussed. It is observed that medical organization has not changed as rapidly as scientific medical research, and that the concern of social policy regarding medicine is with the extent and direction of the development of different types of organized medicine.

The problem is to make available to the whole people the results of scientific research and experiment at a reasonable cost.

In a brief review, it is impossible to do justice to such a comprehensive re-

port of an exhaustive national study of this important problem. An enormous amount of valuable information has been assembled in a manner to stimulate those in responsible positions to consider carefully their program developments and their place in community life.

IRA V. HISCOCK

Chronic Enteric Carriers and Their Treatment—By C. H. Browning, with H. L. Coulthard, R. Cruickshank, K. J. Guthrie, and R. P. Smith. *Special Report Series, No. 179, Medical Research Council, London, 1933.*

Although the morbidity and mortality rate of the enteric fevers—typhoid and paratyphoid A and B—is at present very low in Great Britain, the authors appreciate the fact that such a fortunate situation is due to the hygienic conditions and that a potential source of danger is ever present in the chronic carrier. Their report, including a thorough review of the literature and results of personal researches regarding this subject, is divided into 3 parts—(1) Classification of Carriers: Incidence and Importance, (2) Methods of Laboratory Identification, and (3) Treatment of Enteric Carriers. An appendix gives the histories and records of tests on the carriers studied in the investigation.

Carriers can only be classified when laboratory records are available for as long as a year after clinical recovery since a considerable number of persons excrete the specific organisms for short periods and become cured spontaneously. In most cases, the individual who excretes bacilli after 6 months will continue to do so, and those who are shown to eliminate the organisms after 1 year are classified as chronic or permanent carriers.

More women than men become carriers, and various states of health are observed. The carrier may harbor a

focus in the intestinal canal, gall-bladder, bile ducts or liver tissue, urinary tract, bone marrow, or tonsils, from which the bacilli are often discharged intermittently. The control of the carrier state, which apparently is not affected by previous vaccination, becomes one of personal and community responsibility.

Positive identification of the carrier depends upon the isolation of the specific bacilli. A combination of direct plating on a differential medium such as MacConkey's or Endo's agar and the use of broth containing brilliant green in varying concentration gives the greatest number of positive results.

Widal tests with a proper consideration of O agglutinins are often informative. Complement fixation reactions, skin tests, and blood studies are sometimes significant.

Non-surgical methods of treatment—chemotherapy, physiotherapy and alteration of intestinal flora—of the chronic carrier have proved ineffective. "Operative treatment has now been carried out sufficiently often to show that it offers high likelihood of cure." Removal of the gall bladder where that organ has been proved to be the site of infection, has yielded highly satisfactory results. Three biliary carriers—one of whom submitted to cholecystectomy and two to cholecystgastrostomy—were cured by such surgical procedures. Urinary carriers who are proved to have an unilateral focus are often cured by operative treatment.

As a whole, the chronic carrier has little assurance of a cure.

ANNA DEAN DULANEY

Housing Objectives and Programs
—*The President's Conference on Home Building and Home Ownership. Washington, 1932. 345 pp. Price, \$1.15.*

This publication of the President's Conference on Home Building and

Home Ownership is a summation of work of the Conference and points toward future activities in behalf of the home owner.

The committee on technological developments concludes its discussion with specific recommendations regarding construction of homes at less cost. Its first conclusion indicates a belief that small houses at the present time do not meet reasonable requirements for cost, safety and comfort, and discusses how these shortcomings may be removed.

The committee on legislation and administration approaches the reports of each of the sub-committees of the Conference with the idea of indicating where additional legislation or rulings might be useful. The committee on standards and objectives of housing sets forth a very complete and interesting resumé of its topics. Much consideration has been given to details of homes and home building. Two others of these major committees concern themselves with indicating generally how the good results of the Conference can be brought to the attention of all those interested and how these results can be crystallized into local and national programs for the advancement of the cause. The section concerning research lays out many fields in which additional effort can be directed and points to the value of a privately endowed housing foundation. ARTHUR P. MILLER

Fungous Diseases. A Clinico-Mycological Text—By Harry P. Jacobson, M.D. Springfield, Ill.: Charles C. Thomas, 1932. Price, \$5.50.

The need for a concise study of clinical mycology and the greater interest in the subject in the United States is indicated by the publication during the last 2 years of several books dealing with fungous diseases. This work is concerned chiefly with clinical

mycology, and is intended primarily for medical students and physicians. Until recently, material in the fields of both medical mycology and industrial mycology has been scattered through various American and European textbooks and periodicals.

The author divides the material on fungus diseases into 3 sections, based on the location of the primary lesion and the frequency of systemic involvement. The first section is preceded by a chapter in which there is a brief historical sketch on the origin of mycology, and a number of definitions pertaining to structures of fungi. Section A considers those dermatomycoses which are "Primary cutaneous mycoses with (usually) no definite systemic involvement." The clinical signs, gross and microscopic appearance of cultures, and laboratory procedures for the diagnosis of saprophytic and parasitic dermatomycoses are described. Information concerning the form of the organism in culture, the appearance of the surface, color, location of human lesion, morphology of organisms from lesions, and pathogenicity for animals is given in tabular form for the *Microspora*, *Trichophyta*, *Epidermophyta* and *Achoria*. The diagnosis, differential diagnosis, therapy, and prognosis of these infections is discussed.

In Section B, "Primary cutaneous and/or mucous membrane infections, with frequent systemic involvement" are discussed. These include moniliasis, maduromycosis, sporotrichosis, blastomycosis, actinomycosis and coccidioides. These infections are discussed under the same headings as are those of Section A, and the pathological changes produced are described. A short history of each disease, as well as its distribution, is included in most cases.

It is unfortunate that the author has adhered so rigidly to the use of some of the older terms in classification, particularly in the use of the generic terms

Blastomyces and *Nocardia*, for the causative agents of blastomycosis and actinomycosis. In the case of blastomycosis, it has been pointed out by others that the term was originally used because the organism was thought to be a yeast, although erroneously. The term *Blastomyces* has also been used by some mycologists for one of the *Fungi Imperfecti*. The causative agent of most cases of clinical "blastomycosis" conforms to the requirements of the genus *Oidium*, and this generic name should therefore replace the older one. Although there may be justification for the division of blastomycosis into different clinical types, it is questionable whether these are caused by different species of *Oidium*. In fact, 3 main types of growth which have been described for *Oidium dermatitidis* can be obtained from a single culture by varying the medium and examining the cultures at different ages.

The use of the generic term *Nocardia* for the causative agent of actinomycosis is unsuitable for several reasons, which were discussed by Breed and Conn in an article published in 1919.

Torulosis and Aspergillosis are discussed in Section C which deals with "Primary systemic infections with occasional instances of skin or mucous membrane involvements." While the author makes no claim for the comprehensiveness of this volume, there are some fungus diseases of interest which are omitted, notably infection with *Mucor corymbifer*. Infections of this type would logically fall in the third section of the text.

There are some inaccuracies. On page 125, the causative organism of sporotrichosis is incorrectly described as being Gram-negative when found in the tissues. In only one place has the author mentioned the industrial relationships of the fungi, and it would probably have been better to have

omitted this reference to the commercial use of *Aspergillus niger*, for it is not generally considered as capable of producing pyrogalllic acid, and is certainly not used commercially for this purpose.

The volume is especially well illustrated and printed on excellent paper. It is well written and will be welcomed by clinicians who will be glad to have the information presented in a single volume.

NEWELL R. ZIEGLER

The Development of Mental Health in a Group of Young Children: An analysis of factors in purposeful activity—By *Elizabeth Skelding Moore*. *University of Iowa Studies in Child Welfare*, Vol. IV, No. 6, 1931. 128 pp. Price, \$1.50.

A unique method of investigation has been applied in this study to determine child behavior under varying conditions of child-child, parent-child, and teacher-child contacts. Five aspects of mental life have been studied, namely, initiative, creative ability, perseverance, poise, and friendliness. Three groups of preschool children were enrolled for this research: the main group, consisting of 20 children of 2 and 3 years of age; a second group, composed of 22 children around 4 years of age, for supplementary data; and a third group, composed of 19 children from 2 to 4 years of age, under observation 5 days a week from 9:00 a.m. to 4:00 p.m.

The methods of approach to the problem are stated as follows:

1. Controlled, experimental conditions were set up wherein each child could be observed for his activities and reactions with certain play materials and the results compared. These conditions were set up for each child twice during the year, a semester intervening.

2. A rating scale, providing for judgments on items of child behavior, was scored twice a year by each adult who was familiar with the children.

3. Daily checking for 22 weeks by 3 teachers of all the activities of each child where

adult assistance was needed, a double entry method permitting the recording of the teacher's method of aiding the child in each instance.

4. Observation of each child for a period of 1 hour during the preschool morning about every 2 weeks until 10 hours of observation were made.

5. Visits to the home of each child over a consecutive period of 48 hours.

Some of the main conclusions to this study may be noted.

1. It is clear that children as young as 2 and 3 years of age have already established very different patterns of behavior.

2. Some children exerted effort to attain their purposes, others little.

3. The creative activity varied as widely.

4. In self-reliance the children also varied.

5. In friendliness the same extremes in individual behavior were found on all of the methods used.

6. This study indicates that there are many differences in the environmental influences reacting upon individual children.

The general conclusion reached is that it is possible, through carefully controlled experiments and observations, to analyze various aspects of child behavior in its interaction with the environment. RICHARD A. BOLT

The New Healthy Living Series—By *Winslow and Hahn*. New York: Merrill, 1932. Price, Books I, II, III—\$.64; Book IV—\$.68.

Four books make up the latest *New Healthy Living Series*, which should prove valuable to teachers because of the excellent presentation of interesting subject matter, attractive illustrations, well chosen diagrams, and apt stories. Suggestive pupil activities in the form of questions, experiments, and problems, as well as tests for measuring the knowledge gained, will also appeal to the teacher.

The first book, *The Game of Healthy Living*, aims to develop a positive interest in or desire for health. Aliveness and growth are stressed, together with the part played by foods, sunlight, and exercise in maintaining them.

The Habits of Healthy Living follows logically as the second book, for the child must fix his health habits firmly at an early age. The approach is clever, being the secret of the successful adventures of Lindbergh, Byrd, and Piccard—careful preparation and control based on habit formation.

The reasons for health habits are brought out in the third book, *The Laws of Healthy Living*, which is perhaps slightly technical in its physiology for the elementary school, but nevertheless very readable and sound.

In the last book of the series, *The Healthy Community*, the emphasis naturally broadens to public rather than personal health and presents a fascinating picture to the reader by showing the contributions of such health heroes as Pasteur, Trudeau, and Walter Reed.

This series is scientifically accurate in subject matter, with the possible exception of one or two overstatements of facts still open to debate, such as the harmful effects of tobacco upon the appetite, digestion, and heart. One or two statements concerning Oriental diet and clothing would also bear investigation. The advice given is in general sane and practical. The books are carefully planned and well executed, so that they should prove decidedly useful to teacher and pupil alike.

MARGARET ROBERTS

Health Section Report of the Denver Meeting—World Federation of Education Associations—Published by the American Child Health Association and the Metropolitan Life Insurance Company, New York, 1932, 300 pp.

This report is similar in nature to those issued from the previous meetings of the Health Section. It contains reports of school health programs or special and distinctive pieces of school health work in Australia, Belgium,

China, Czechoslovakia, England, Finland, France, Germany, India, Italy, Japan, Poland, Sweden, and the United States. Special sections are devoted to (1) nutrition and other phases of the school health program, (2) the integrated health program in elementary and secondary schools, (3) the health program in teacher education, (4) the health service program, (5) technique for developing sound health literature and other materials, and (6) activities promoting home and school coöperation. One of the sessions was a joint session with the Department of Home and School. The continuing program of the Health Section is described.

Through a contribution of funds and services from the Metropolitan Life Insurance Company and the American Child Health Association, this book has been carefully edited, attractively printed, and made available at printing costs. It reflects appreciable progress in the improvement of the school health program and particularly health education in the United States and in the other countries mentioned. It probably presents the best available picture of current school health activities throughout the world. Papers have been reduced to concise, meaty, but readable form.

Only a limited edition has been issued, so workers in health education and other phases of the school health program should secure a copy while the volume is still in print.

C. E. TURNER

The Chemistry of Tuberculosis—By H. Gideon Wells and Esmond R. Long. (2d ed.) Baltimore: Williams & Wilkins, 1932. 481 pp. Price, \$7.00.

This book, which serves as an excellent reference to the vast store of literature in the field that it covers, has been thoroughly revised. The volume is divided into 3 sections dealing with

the chemistry of acid fast bacteria, the chemical changes in the tuberculous host, and the chemotherapy of tuberculosis.

The review of the chemistry of acid fast bacteria is prefaced by a brief discussion of the recognized variations occurring in the typical bacilli usually associated with tuberculosis. The significance of these variants and their relation to the chemical investigation of laboratory cultures is well brought out. The first section has been improved by a more logical arrangement, and a wealth of new data on the composition of the bacillus and its metabolic products is now presented. It includes studies on the nutritional requirements of the tubercle bacillus, the composition of representative organisms of all the principal types of acid fast bacilli, and the chemical composition of tuberculin. A discussion of the factors regarded as responsible for the property of acid fastness forms an interesting chapter.

The second section considers the chemical changes in tuberculous tissues and the chemical properties of the various fluids and excretions of the tuberculous host. The collection and correlation of the information relative to the blood, effusions, sputum, and urine in tuberculous individuals constitutes one of the notable features of the book. The chapter on the metabolism in tuberculosis should be of interest to every physician treating the disease.

The section on chemotherapy has undergone less alteration than the rest of the book—a rather striking illustration of the fact that research directed toward the cure of tuberculosis is seeking other fields. The rôle of calcium as a therapeutic agent is excellently presented and serves to clarify a highly controversial subject.

The excellent summaries at the end of the principal sections are very helpful, but the reviewer feels that the

value of the work would be enhanced by a more pointed evaluation of the various data presented throughout the volume. The student might also wish to find a more thorough review of the chemical aspects of immunity in tuberculosis—a subject which the authors are preëminently fitted to discuss.

The book is comprehensive, lucid, and unusually well edited. It should be a constant companion of every student of tuberculosis.

DONALD E. CUMMINGS

Water Purification Control—By Edward S. Hopkins. Baltimore: Williams & Wilkins, 1932. 131 pp. Price, \$1.75.

This short, non-technical guide in water purification plant control fills a current need. With the exception of one chapter on plant control data, it explains the processes involved in water purification, and the application of the various chemicals used therein.

ARTHUR P. MILLER

Standard Methods for the Examination of Water and Sewage, Seventh Edition—By the American Public Health Association and the American Water Works Association. New York: 1933. 180 pp. Price, \$2.00.

The manual as a whole has been considerably enlarged by the addition of new chapters in chemical and microscopical methods and by the inclusion of a new feature, that of non-standard methods both chemical and bacteriological which have not as yet had sufficient use to warrant their adoption as standard methods. The table of contents with its new grouping of subject material is more concise and more easily available than in previous editions.

In view of the growing tendency to consider microscopic examinations of bottom sediments and plankton a valu-

able source of information as to the sanitary status of a sewage-polluted stream, the revision and enlargement of this section of the manual should prove a timely aid to those interested in stream control work.

In the chemical section a few new methods have been added, a few omitted, and some, such as total hardness, turbidity measurements, and quantitative estimation of chlorine, have been rewritten and revised. The biochemical oxygen demand method has been entirely revised and standardized in accordance with the present accepted procedures as recommended by the joint B. O. D. committee report.

A chapter on rapid methods of boiler water analysis is a step toward uniformity in this field.

Bacteriological standard procedure has been changed but little from previous editions. The brilliant green lactose peptone bile method in conjunction with standard lactose broth has been added for the control of waters in the process of purification. Whether this test, recommended for unfinished waters only, will prove to be a saving in time and a better index of plant conditions than the standard method remains to be reported upon by plant operators.

The printing and arrangement of the manual make for a readable, usable laboratory guide, and on the whole this seventh edition seems to have fulfilled admirably its attempt to revise and standardize the older procedures and to include only the best and most promising of the newer methods.

ALICE EXWORTHY

Farm and Village Housing—The President's Conference on Home Building and Home Ownership—Vol. VII. Washington, D. C., 1932. 293 pp. Price, \$1.15.

This volume deals with the special problems of housing and environment presented by farms and rural communi-

ties in direct contrast with city housing problems.

The book is divided into several parts, dealing successively with existing farm and village housing conditions; existing design and construction with suggestions for improvement and for building new houses; farm beautification; economic and financial aspects, including values of dwellings, financing building and improvements, taxation, and insurance problems, special phases and problems, which include housing and health and migratory labor; educational objectives and methods, needed research programs, and recommendations.

Various appendices give the activities of several rural organizations, housing conditions among the Indians, and a list of references.

The volume brings out forcibly the low value of rural dwellings in different sections of the country and points out that architects in general have overlooked the special needs of farmhouses in designing single-family dwellings. Also, that a lower cost structure is needed compared with prices of city dwellings. Too much territory has been covered in too short a time and consequently parts of the book are rather sketchy. The volume will, however, serve as a starting point from which further studies of rural housing and the peculiar problems attendant thereto may be made.

VINCENT B. LAMOUREUX

The Rheumatic Infection in Childhood—By Leonard Findlay, M.D. New York: Wood, 1932. 187 pp. Price, \$3.50.

Written by a man with long service as physician to the Royal Hospital for Sick Children of Glasgow, this book carries the authority of careful observation and ample experience. The basis of the treatise rests on 701 cases of rheumatism, of which all but 8 have

been completely followed up, some having been under observation for 15 years.

Each of the various manifestations of rheumatism has a chapter to itself and there is a chapter on prognosis and one on treatment. There is a good bibliography at the end of each chapter, particularly in respect to European references.

For the clinician in the public health field this book will be of considerable interest. MERRILL E. CHAMPION

Planning and Building the City of Washington—*Edited by Frederick Haynes Newell. Washington, D. C.: Rensdell, Inc., 1932. 254 pp. Price, \$2.00.*

The planning and building of the city of Washington are presented in this small book, a product of the efforts of the Washington Society of Engineers and cooperating agencies and persons. It is well illustrated and contains much of interest to those desirous of seeing L'Enfant's vision carried through.

ARTHUR P. MILLER

BOOKS RECEIVED

THE EXAMINATION OF WATERS AND WATER SUPPLIES. 4th Ed. By John Clough Thresh, John Foster Beale and Ernest Victor Suckling. Philadelphia: Blakiston, 1933. 824 pp. Price, \$9.00.

TOWARDS MENTAL HEALTH. The Schizophrenic Problem. By Charles Macfie Campbell. Cambridge: Harvard University Press, 1933. 110 pp. Price, \$1.25.

SELECTED RECREATIONAL SPORT FOR GIRLS AND WOMEN. By Julia H. Post and Mabel J. Shirley. New York: Barnes, 1933. 132 pp. Price, \$2.00.

LABORATORY MANUAL. Methods of Analysis of Milk and Its Products. Compiled by International Association of Milk Dealers, 228 North La Salle St., Chicago, Ill., 1933. 461 pp. Price, \$5.00 to members, public health officials and colleges. \$7.50 to others.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Immunization by Clinic and Practitioner—These conclusions are reassuring: "In the 26 communities studied, those showing the highest public immunization rate against diphtheria show also the highest private immunization rate (judged by numbers of ampules distributed to practising physicians). . . . Those communities doing the most . . . immunizations show the greatest improvement over seven years in the incidence of diphtheria."

ANDERSON, G. W. and BIGELOW, G. H. Diphtheria Immunization and the Private Practitioner. *New Eng. J. Med.* 208, 15:781 (Apr. 13), 1933.

Nurses Stimulate Diphtheria Immunization—Diphtheria mortality in Chicago has been reduced by having nurses call on all children's parents urging that the immunization be done by the family physician. The church has proved a potent aid in dealing with foreign-born groups. Literature is a valuable aid to nursing calls. By itself it will not have much effect.

BUNDESEN, H. N. *et al.* Diphtheria Control in Chicago. *J.A.M.A.* 100, 14:1093 (Apr. 8), 1933.

The Statistician Looks at the Heart—Study of 2,000 cases of heart disease revealed an average age of 51, with males younger than females. The causes were rheumatic infection, 27 per cent; hypertension, 20 per cent; arteriosclerosis, 8.8 per cent; syphilis, 4.6 per cent. Other suggestive findings are recorded.

DEPORTE, J. V. Heart Disease in General Medical Practice. *Am. Heart J.* 8, 4:475 (Apr.), 1933.

The Truth about Phage—The reasons for the lack of therapeutic re-

sults following the administration of phage in experimental animals are thoroughly explored. Hopeful phage proponents will get no comfort from this summary.

EVANS, A. C. Inactivation of Antistreptococcus Bacteriophage by Animal Fluids. *Pub. Health Rep.* 48, 16:411 (Apr. 21), 1933.

Possibilities in Rural Sanitation—What has been done to improve community sanitation in Cattaraugus County is recounted in interesting detail.

FULLER, N. M. What a County Unit Can Accomplish in Public Health Engineering. *Municipal Sanitation* 4, 4:119 (Apr.), 1933.

Measles Prophylaxis with Adult Blood—During a measles epidemic the use of 10 c.c. of whole blood, preferably from a parent, will modify but not prevent the disease, reduce the incidence of complications, and the resulting immunity from the attenuated infection will be permanent. Much larger amounts of blood are necessary to protect.

KAISER, A. D. Value of Immune Adult Blood in the Treatment of Measles. *New York State J. Med.* 33, 8:521 (Apr. 15), 1933.

American Experience with BCG Vaccination—"1. Our 5-years' study on 413 BCG vaccinated babies indicates that BCG vaccination is harmless. 2. The vaccinated children show a lower tuberculosis mortality than similar controls. . . . 5. Parenterally vaccinated children become tuberculosis positive in 84 per cent of the instances, whereas the orally vaccinated children become so only in 40-50 per cent of the cases. . . . 7. As a whole, the parentally BCG vaccinated children show the lowest tuber-

culosis mortality of all the groups."

KERESZTURI, C. *et al.* Clinical Study of BCG Vaccination. *New York State J. Med.* 33, 6:375 (Mar. 15), 1933.

Possibilities in Prophylaxis—Brief and timely is this simply written summary of the use of biologicals in the prophylaxis and treatment of diphtheria, scarlet fever, tetanus, meningitis, pneumonia, poliomyelitis, measles and typhoid. It even explains the difference between a vaccine and a serum, which still remains a mystery to many sanitarians.

LONG, P. H. Communicable Diseases. *Am. J. Nurs.* 33, 4:303 (Apr.), 1933.

Dissertation on Spinach of Many Varieties—Spinach is found to contain a large part of the alphabet. Mothers are thereupon made to believe, not that spinach is wholesome, but that it is an indispensable part of the child's diet. The child is goaded into eating an unpalatable mess, or into open rebellion. "There are too many dictatorial statements made about spinach and kindred matters," says the author. "Other matters" in this instance represent the spinach in mental hygiene.

MYERSON, A. Sanity in Mental Hygiene. *Ment. Hyg.* 17, 2:218 (Apr.), 1933.

A Poser for BCG Vaccinationists—Apparently the opinion that infected individuals are protected against tuberculosis must be abandoned, for primary tuberculosis infections which produce allergy to tuberculin do not prevent consumption from developing later. Then, concludes the author, "Active immunization against tuberculosis with attenuated bacilli may not be a safe

procedure if this method immunologically duplicates the changes that accidental human contact infection produces."

STEWART, C. A. Does a Primary Tuberculous Infection Afford Adequate Protection Against Consumption? *J.A.M.A.* 100, 14:1077 (Apr. 8), 1933.

Truth About Toddlers—Candor and good common sense applied to the preparation of the child for life in school set this paper apart. It should be read and pondered over. Vaccination, tonsillectomy, tooth-building, nutrition, handicaps and posture all come in for critical scrutiny. An excellent paper.

ROGERS, J. F. Preparing the Child for School. *Pub. Health Nurs.* 25, 5:257 (May), 1933.

Male Birth Ratio Increases—The male sex-ratio for Canadian births is 105-106. Stillbirths, in which the male sex-ratio is much higher, are declining; hence there is an increasing ratio among the live-births. Other interesting statistical findings are recorded.

WYLLIE, J. Sex Differences in Infant Mortality. *Canad. Pub. Health J.* 24, 4:177 (Apr.), 1933.

Pointing the Main Chance for Infant Mortality Improvement—New York City's infant deaths studied in relation to place, age period, and causes reveal the usual findings and raise the question whether better obstetrics might not be the most potent measure for improvement.

NATIONAL TUBERCULOSIS ASSOCIATION

IN place of the course on Health Problems Involved in the Teaching of Fresh Air Classes, the course which the National Tuberculosis Association has been offering for the past 2 years at Teachers College, Columbia University, New York, a course on Health Problems and Protective Care will be substituted. Every school administrator, supervisor, and teacher is confronted every day with the problem of how to deal with children whose health is below par. It is not possible or practical to segregate in special classes all children needing "protective care," but it is both possible and practical to give these children found in every school, large and small, the "extra lift" needed to help them increase their resistance to infection and to improve their health status. The new course is planned to meet this problem. The course will be given from July 10 to August 18, 1933.

MENTAL HYGIENE MOVEMENT

CELEBRATES

ON May 6, the 25th anniversary celebration of the mental hygiene movement was held in New Haven, Conn., where the movement was founded by Clifford W. Beers, a graduate of Yale, shortly after the publication of his autobiography, *A Mind That Found Itself*. A program was arranged under the joint auspices of the Connecticut Society for Mental Hygiene, which was organized by Mr. Beers in 1908, The National Committee for Mental Hygiene, of 450 Seventh Ave., New York, which he founded in 1909 and of which he is the Secretary, and Yale University.

Among the speakers were the Hon. Wilbur L. Cross, Governor of Connecticut; Dr. James R. Angell, President of Yale University; Dr. C.-E. A. Winslow, Professor of Public Health, Yale University; and Mr. Beers.

National mental hygiene societies are now in existence in 30 countries.

On May 11, the Gold Medal of the National Institute of Social Sciences was presented to Mr. Beers at the annual dinner of the Institute held in New York. In recognition of his work in the international field, the French Government has recently conferred upon Mr. Beers the Cross of Chevalier of the Legion of Honor.

NORTHERN CALIFORNIA ASSOCIATION

ELECTS OFFICERS

AT its recent meeting, the Northern California Public Health Association elected the following officers:

President, Dr. Herbert F. True, of Sacramento; *President-Elect*, Professor Leon B. Reynolds, of Stanford University; *Vice President*, Eleanor Stock-

ton, of San Francisco; *Secretary*, Dr. Walter Brown, of Stanford University; and *Treasurer*, Mary Davis, of San Francisco.

MAX C. STARKLOFF

WE regret extremely to note the retirement of Dr. Max C. Starkloff from the position of Health Commissioner for the City of St. Louis. Dr. Starkloff was appointed first in 1895, and served until 1903. In 1911 he was again appointed, and has served to date. His first appointment was made 38 years ago, and he has actually served the city 30 years.

His administration has been marked by notable advances in the public health idea as well as his efficiency in applying new knowledge as it came forward. Soon after taking office came the disastrous cyclone of May 26, 1897. Within 6 hours after the storm, a vacant institution had been commandeered, equipped with emergency cots; and put into operation. For some 18 years this remained the City Hospital until new buildings were acquired.

Among Dr. Starkloff's notable accomplishments have been his constant fight for vaccination against smallpox. Through his aid, the City Board of Education maintained its rule for compulsory vaccination of all children within the public schools. The record shows that not one child ever contracted smallpox in the public schools.

Among his notable efforts was the fight against quacks, and he was successful in driving many charlatans out of the city. He was responsible for the establishment of 10 dental clinics. In 1914 he succeeded in obtaining an ordinance for the pasteurization of all milk, which failed to be upheld by the Supreme Court after many years of litigation. However, a new ordinance was passed, and at present the pasteurization of practically all milk in the city has been adopted. All milk sold in St.

Louis comes from tuberculin tested herds. St. Louis has the distinction of being the only city which authorizes the Commissioner to furnish dogs to the Medical Society for teaching and scientific purposes.

Under Dr. Starkloff's administration the department has grown from what might be called a small office engaged in the activities looking to the prevention of disease, to 16 bureaus: epidemiology, bacteriology, chemistry, vital statistics, food control, including milk, dairies, child hygiene, prenatal and postnatal work, dental prophylaxis, meat inspection (antemortem and postmortem), tuberculosis, venereal disease clinic and treatment, social service, public health education.

All honor to the veteran of public health who has accomplished so much during his years of public service. Fortunately for the city and public health in general, an excellent successor has been appointed. Further than this, all appointment in the Health Office are being recommended by a Board of Physicians and are made on the basis of quality and efficiency rather than politics.

INDIANA

THE long-awaited program of Governor Paul V. McNutt for the complete reorganization of the Indiana state government into 8 central departments became effective April 15.

With it came the grouping of approximately 100 state boards, commissions, bureaus, and departments into 8 major departments. Some departments that have been in existence for generations will lose their identity, others will be dispensed with, and still others will be merged.

Under the department of commerce and industry will fall the State Board of Health and its allied bureaus.

Many functions of the present board will be shifted to the Indiana University

School of Medicine. Through the discharge of 19 employees in the State Board of Health, Governor McNutt said more than \$33,500 would be saved annually. Among those holding important positions with the old board who will be dropped under the new scheme are Drs. William F. King, H. W. McKane, C. F. Adams, and Ada E. Schweitzer, all four Fellows of the A.P.H.A. Further changes in the health department will account for \$100,000 additional savings, the Governor said.

Dr. John H. Hare, Evansville physician, has been appointed executive secretary of the state board of health. Dr. Hare will succeed Dr. William F. King, who has been associated with the state health board many years as assistant and as secretary since 1925, when he succeeded Dr. William Hurty.

CHILD HEALTH ASSOCIATION CONFERENCE

AT the invitation of the University of Michigan Summer Session, the American Child Health Association will hold its seventh Health Education Conference at Ann Arbor, Mich. The conference will open on June 20 and close on June 24. Dr. John M. Sundwall, Director, Division of Hygiene and Public Health, University of Michigan, will be the General Chairman.

PENNSYLVANIA PUBLIC HEALTH ASSOCIATION MEETING

AT the Ninth Annual Meeting of the Pennsylvania Public Health Association, held at Wilkes-Barre, Pa., May 16 and 17, the following officers were elected:

President, C. B. Crittenden, M.D., Wilkes-Barre; Vice-President, James Smith, M.D., Erie; Secretary-Treasurer, A. J. Bohl, Harrisburg; Executive-Secretary, J. Clarence Funk, Harrisburg.

The Tenth Annual Meeting will take place at Philadelphia in May, 1934.

HEALTH DURING THE WORLD'S FAIR

PRECAUTIONS are being taken by the Chicago Health Department for health of the visitors to the Century of Progress Exposition during the coming summer. Particular attention will be paid to water and sewage disposal, purity of food and milk, examination of employees, and adequate comfort stations and drinking fountains. The department will have complete control over all other health matters.

The fair grounds will be under the same health supervision as the rest of the city. Tourist camping grounds within the city limits will also be under strict supervision, while outside camps will be under the control of state authorities. Tourist camps desiring the sponsorship of A Century of Progress must submit their plans for sanitary facilities and the control of communicable diseases to the Health Department for approval before any action will be taken by exposition officials. Food handlers have already been examined for communicable disease.—*J.A.M.A.* 100, 17 (Apr. 29), 1347.

TEXAS SHORT SCHOOL ON SWIMMING POOLS

THE Fifth Annual Short School was held at San Marcos, Tex., on May 6. It was devoted to the subject of Swimming Pools.

PARENTS-TEACHERS CONGRESS IN SEATTLE

THE 37th Annual Convention of the National Congress of Parents and Teachers was held at Seattle, Wash., May 21-26. The theme was The Child and His Community.

MARYLAND-DELAWARE ASSOCIATION

THE Seventh Annual Conference of the Maryland-Delaware Water and Sewerage Association was held in Baltimore, May 4 and 5.

CLOSING DATE FOR SUBMISSION OF
FELLOWSHIP APPLICATIONS

ALL members desirous of applying for Fellowship are hereby advised that their applications must be transmitted to the Executive Office not later than August 10, if they are to be finally acted upon by the Governing Council at the Indianapolis Annual Meeting.

ACTIVITIES OF LEAGUE OF MENTAL
HYGIENE IN BRAZIL

THE Brazilian League of Mental Hygiene, the tenth anniversary of which was recently celebrated, established in December, 1932, a mental hygiene clinic for children, the first of its kind in Latin America. This clinic, in charge of a physician assisted by psychologists, psychiatrists, and social workers, combines the work of a habit clinic for preschool children with that of a child guidance clinic for school children and emphasizes the prevention of mental disorders. The work with children under 2 years consists in watching their mental development; with children between 2 and 6 the purpose of the work is the formation of proper traits of mentality and personality; and with children between 6 and 12 the purpose is their correction and guidance.

The league is studying, through special committees, mental hygiene of children, social legislation, social aid, prevention of delinquency, and other subjects. It holds an anti-alcohol week every year, and is conducting a very extensive educational campaign through its literature and the daily press.—*Archivos Brasileiros de Hygiene Mental*, Rio de Janeiro, 1932, No. 2.

DEATH

DR. MARTIN DEWEY, former president of the American Dental Association, the Kansas City Dental Society, and the First District Dental Society of the State of New York, died May 14.

PERSONALS

CAREY P. MCCORD, M.D., F.A.P.H.A., of Cincinnati, O., was given his Honorary LL.D. on May 30, by Howard College in Birmingham, Ala., for his services in reducing the occupational hazards in the life of the industrial worker.

MILTON J. ROSENAU, M.D., Fellow A.P.H.A., Professor of Preventive Medicine and Hygiene at the Harvard University Medical School, Boston, will give two courses at the summer session of the University of California at Berkeley.

HENRY C. SHERMAN, Ph.D., Fellow A.P.H.A., in recognition of his research on food and his service in the training of chemists, has been awarded the medal of the American Institute of Chemists at the annual meeting of the institute in New York in May. The award is given each year for outstanding service to chemistry.

DR. WILLIAM B. GRAYSON, of McGehee, Ark., was elected Arkansas State Health Officer and secretary of the Board of Health, replacing Dr. Charles W. Garrison, who has served in the position 18 years.

W. W. PETER, M.D., Dr.P.H., Fellow A.P.H.A., formerly Associate Secretary of the A.P.H.A., has been granted an Oberlaender Trust Fellowship. He expects to sail on June 25 for 6 months in Germany and Austria, to study the visualization aspects of the public health education movement in those countries. In January, February, March, 1934, at the request of the Near East Foundation, he will make a survey of their medical and public health work in Albania, Bulgaria, Greece, Macedonia, Palestine, Syria, and Turkey. On behalf of American physicians in Persia, an invitation has also been extended to him to

visit medical and educational centers in that country in April. He expects to return to the United States by May 1, 1934.

E. S. GODFREY, JR., M.D., F.A.P.H.A., director of local health administration, New York State Department of Health, was elected president of the American Epidemiological Society at their annual meeting in Washington, D. C., on May 8.

HOMER N. CALVER, F.A.P.H.A., Secretary-Treasurer of the New York State League of Savings and Loan Associations, announces that the headquarters office of this League will soon be located at 30 Rockefeller Plaza, New York.

DR. JOSEPH F. BREDECK is the new Health Commissioner of St. Louis, Mo., replacing Dr. Max C. Starkloff, veteran public health officer, and Fellow A.P.H.A. Dr. Ralph L. Thompson has been appointed hospital commissioner replacing Dr. C. H. Lohr.

DR. EDWIN R. VANDERSLICE has been appointed director of the Lansing Health Department. He was for years director of the Michigan Tuberculosis Association.

DR. BYRON L. PAMPEL, of Livingston, Mont., was recently elected president of the Montana State Board of Health.

CONFERENCES

June 2-3, Eighth Annual Meeting of the New England Health Education Association, Cambridge, Mass.

June 5-6, State and Provincial Health Authorities of North America, Washington, D. C.

June 5-6, State and Territorial Health Officers Conference, Washington, D. C.

June 11-17, National Conference of Social Work, Detroit, Mich.

June 12-17, Meeting of the American

Medical Association, Milwaukee, Wis. June 20-24, American Child Health Association Health Education Conference, Ann Arbor, Mich.

June 26-30, National Tuberculosis Association, Toronto, Canada.

June 26-30, Annual Meeting of the American Home Economics Association, Milwaukee, Wis.

June 27-July 1, Convention of the Association for Childhood Education, Denver, Colo.

June 28-July 3, International Hospital Congress, Knocke-sur-Mer, Belgium.

July 1-7, National Education Association, Chicago.

July 3-7, Association for Childhood Education, Denver, Colo.

July 3-8, British Social Hygiene Council Imperial Congress, London.

July 5-9, International Union of the Protection of Childhood, Paris.

July 10-15, International Council of Nurses, Paris, July 10-12; Brussels, July 13-15.

Diphtheria Immunization in Private Practice

GAYLORD W. ANDERSON, M.D., AND
GEORGE H. BIGELOW, M.D., D.P.H., F.A.P.H.A.
Massachusetts Department of Public Health, Boston, Mass.

DIPHTHERIA prevention through mass immunization in public clinics has become so generally accepted as a sound public health procedure that too little attention has been given to the part played by the physician in his family practice. It has been said that these clinics deprived the practicing physicians of the opportunity to carry out such immunization in their practice, inasmuch as the public would not pay the usual office fee for service obtainable free in a public clinic. On the other hand, certain physicians have testified that the conduct of an active diphtheria prevention campaign within a given city stimulated a demand for this service among their clientele. These conflicting views have almost invariably been based on personal opinions, adherents of both doctrines being found in all communities, and neither having anything but the most limited factual data to support the conclusions. In a previous communication* we have given the results of a preliminary study designed to measure the extent to which the public conduct

of diphtheria immunization clinics may stimulate a demand for immunization in the private physician's office. In the present paper we have made further and more complete analysis of these data.

Although figures as to immunization clinics are relatively easy to obtain, it is virtually impossible to learn exactly the number of children that may be immunized in private practice. Lacking such information, we have used in this study the amount of toxin-antitoxin in individual doses supplied to the different communities under observation as an index of immunization in private practice.

In Massachusetts toxin-antitoxin is furnished by the State to all boards of health and physicians free of charge. This is supplied in vials of 20 c.c. for clinic purposes, and in packages of three 1 c.c. ampoules for office use by physicians. It has been assumed in this study that the use of these 1 c.c. ampoules has been limited to private practice. This assumption has been checked in certain of the communities using the greatest amounts, and found to be essentially correct. It is entirely reasonable that it should be, owing to

* *New Eng. J. Med.*, Apr. 13, 1933, pp. 781-82.

the time that would be consumed were the individual ampoules used in a clinic. Thus we feel that within reasonable limits the use of such ampoules constitutes a rough index of the extent of immunization in private practice. There is, of course, the possibility that in some instances the large 20 c.c. vials may have been issued for an individual. Although such use has been denied by those boards issuing such supplies to physicians, it would certainly be a rather constant error from one community to another. To ignore such use, if it exists to an appreciable extent, is simply to underestimate the extent of private immunization and therefore to err on the side of conservatism.

Using the above mentioned assumption as a point of departure, we have studied the distribution of these ampoules for the years 1925-1931, inclusive, in all Massachusetts communities above 20,000 population, with the exception of Boston, Pittsfield, and Framingham. The city of Boston was omitted because its position as a center of a large metropolitan area can only mean that many of the ampoules credited to the city will have been used by Boston physicians for the treatment of children from suburban communities. The converse would hardly be true as relatively few Boston children are cared for by physicians with suburban offices. The number of ampoules taken from suburban distributing centers and used in Boston would then be small and fairly constant for all communities. Similarly constant would be the use of toxin-antitoxin ampoules in a community adjacent to that to which it was charged. The city of Pittsfield and the town of Framingham were likewise omitted from the study, due to the impossibility of obtaining sufficiently accurate figures as to immunization clinics.

There remain for study 35 cities and

towns with a total population slightly in excess of 2,000,000. The figures used in estimating the extent of immunization in public clinics are those furnished each year by the local board of health or school committee to the State Department of Public Health. The figures of toxin-antitoxin are those of recorded distribution from the State Antitoxin and Vaccine Laboratory at Forest Hills.

For purposes of comparison the average clinic immunization rate for each community for the 7 years under study has been computed, using as a rate the number of children immunized per year per 1,000 population. Relative immunization rate in private practice is calculated as the number of ampoules used per year per 1,000 population. Inasmuch as each child immunized means the use of three ampoules, the actual rate would be determined by dividing the relative rate by 3. The rate based on ampoules rather than on children immunized is preferable inasmuch as the differences between whole numbers can be more readily noted at a glance than differences between fractions, making the trend more easily recognized.

TABLE I
AVERAGE DISTRIBUTION OF TOXIN-ANTITOXIN
AMPOULES—ALL COMMUNITIES

| <i>Average Clinic Immunization Rate per Year per 1,000 Population</i> | <i>Average Ampoules T-A-T per Year per 1,000 Population</i> | <i>Weighted Average Ampoules T-A-T per Year per 1,000 Population</i> |
|---|---|--|
| Less than 5 | 4.1 | 3.0 |
| 5-10 | 6.7 | 4.7 |
| 10-15 | 7.2 | 6.8 |
| 15-20 | 7.9 | 7.2 |
| *20+ | 8.5 | 7.0 |

* Many of these rates are of course in excess of the birth rate. This is possible only during the first few years of an immunization campaign.

In Table I is shown the use of ampoules in communities separated into 5 groups, according to public clinic

immunization rates. The average use of ampoules for the several communities comprising each group is shown in the second column, whereas the third column shows the same figures weighted for differences in population of the communities studied. It will be noted that in those communities immunizing less than 5 children per year per 1,000 population the use of ampoules was at a minimum and that as the clinic immunization rate increased there was a progressive increase in private immunization rates. These differences are particularly striking among the communities with the lower rates.

The figures in Table I are as complete as it is possible to obtain. They include, however, several communities, the immunization figures for which are open to considerable doubt, in many cases being in excess of the number of immunizations obtainable from the quantity of toxin-antitoxin in 20 c.c. vials furnished to them. The discrepancies may be due in part to the inclusion of certain children Schick tested and found negative. This inclusion might be fair if all the communities followed this plan, inasmuch as it represents children reached through the immunization program, but the majority do not include the Schick negatives in their reports. Because of the rather

ing which there might be reasonable doubt. This leaves a group of 26 cities and towns with a total of over 1,600,000 population. Table II shows the toxin-antitoxin ampoule distribution in these several communities grouped as in Table I according to the intensity of the immunization programs conducted. It is obvious that in these as in the larger unselected group the demand for immunization in the physician's office, as measured by the distribution of the individual toxin-antitoxin ampoules, varies directly with the extent of clinic immunization under official auspices.

It may be pointed out that in the foregoing figures no account has been taken of inevitable wastage of toxin-antitoxin, and that certain communities may have ordered more ampoules than were actually used. This objection is a valid one as it is well known that certain communities over-order all biological supplies to a far greater extent than do others. In Table III an attempt has been made to correct for this wastage.

The immunizations claimed by the several communities have been compared with the amount of toxin-antitoxin furnished for clinic use in 20 c.c. vials. Although each of these vials contains enough material for $6\frac{2}{3}$ complete immunizations, it has been

TABLE II

AVERAGE DISTRIBUTION OF TOXIN-ANTITOXIN
AMPOULES—SELECTED COMMUNITIES

| Average Clinic Immunization Rate per Year per 1,000 Population | Average Ampoules T-A-T per Year per 1,000 Population | Weighted Average Ampoules T-A-T per Year per 1,000 Population |
|--|--|--|
| Less than 5 | 4.8 | 4.1 |
| 5-10 | 7.2 | 4.8 |
| 10-15 | 7.0 | 6.2 |
| 15-20 | 7.7 | 7.1 |
| 20+ | 12.4 | 10.0 |

TABLE III

AVERAGE UTILIZATION OF TOXIN-ANTITOXIN
AMPOULES—SELECTED COMMUNITIES

| Average Clinic Immunization Rate per Year per 1,000 Population | Average Ampoules T-A-T per Year per 1,000 Population | Weighted Average Ampoules T-A-T Used per Year per 1,000 Population |
|--|--|---|
| Less than 5 | 3.2 | 3.0 |
| 5-10 | 3.9 | 2.6 |
| 10-15 | 4.2 | 3.8 |
| 15-20 | 5.5 | 5.4 |
| 20+ | 7.3 | 6.6 |

obvious discrepancies in the immunization figures of several communities, it has seemed fair to discard those regard-

arbitrarily assumed that in clinic practice only $5\frac{1}{2}$ immunizations per vial can be realized. This allows an ample

margin for the inevitable wastage and has been shown in practice to be reasonable. For example it has been assumed that a community which achieved only 2.75 immunizations per vial supplied has utilized effectively only 50 per cent of the material furnished ($2.75 \div 5.5 = 0.5$). This represents the avoidable wastage due in large part to over-ordering. It is reasonable to assume that a similar wastage has existed with respect to individual ampoules which are used in private practice.

A correction factor measuring the extent of utilization has thus been obtained for each of the selected communities and this factor applied to the number of ampoules supplied to the same community. There has thus been obtained a corrected value for ampoule distribution which probably represents more closely the number of ampoules actually used by the physicians in their private practice. Table III is constructed on the same basis as Tables I and II, except that it utilizes these corrected values. It shows even more strikingly than did the previous tables that the demand for immunization in private practice varies directly with the intensity of the clinic program.

The economic situation in the several communities might logically be thought to be a factor in determining the private immunization rate. Thus it would appear at first glance to be reasonable to suppose that in an economically well-to-do community the demand for immunization in the physician's private office would be greater than in the poorer and strictly industrial city. It might likewise be argued that the better the economic condition of the community the more active a diphtheria immunization program would be conducted and that the private immunization rate was dependent on the former rather than the latter. In Table IV an attempt has been made to evaluate this economic influence. The table shows for the year ending March 31, 1931, the average per capita public welfare expenditures of the communities grouped on the same basis as in Tables I and II. This gives some estimate of the relative economic status of the communities. It is at once apparent from this table that there is no correlation between the relative indigency of the community and the immunization rate. The increase in demand for private immunization demonstrated above cannot, therefore,

TABLE IV

ECONOMIC STATUS OF COMMUNITIES ACCORDING TO CLINIC IMMUNIZATION RATES
Per Capita Public Welfare Expenditures

| Average Clinic Immunization Rate per Year per 1,000 Population | All Communities | | Selected Communities | |
|--|-----------------|------------------|----------------------|------------------|
| | Crude Average | Weighted Average | Crude Average | Weighted Average |
| Less than 5 | \$3.63 | \$3.74 | \$3.56 | \$3.60 |
| 5-10 | 3.83 | 3.94 | 3.29 | 3.70 |
| 10-15 | 3.79 | 3.67 | 3.77 | 3.72 |
| 15-20 | 3.75 | 4.32 | 3.99 | 4.50 |
| 20+ | 3.44 | 3.41 | 2.90* | 2.59* |

* The low figure here is due to an extremely low welfare expenditure in one community which in population exceeded the total of the others in the group. In this city, however, the ampoule distribution and utilization was markedly less than the average for the other communities in the same group. This is not, therefore, inconsistent with the general conclusions that no correlation exists between economic status and immunization rate.

TABLE V

COMPARISON OF IMMUNIZATION RATES AND AMPOULE DISTRIBUTION IN CERTAIN CITIES

| | <i>Average Clinic Immuniza- tion Rate per Year per 1,000 Population</i> | <i>Average Ampoules T-A-T Supplied per Year per 1,000 Population</i> | <i>Corrected Average Ampoules T-A T Used per Year per 1,000 Population</i> |
|--------------|---|--|--|
| Fall River | 16.9 | 9.8 | 7.5 |
| New Bedford | 3.3 | 2.5 | 1.5 |
| Cambridge | 15.8 | 5.0 | 4.5 |
| Somerville * | 0.0 | 1.5 | 1.0 |

* In 1932 Somerville has carried on an active clinic immunization campaign. It will be interesting to study its effect on orders for ampoules from this city.

be explained on the supposition that a less indigent population has demanded a greater private service.

In the foregoing tables no attempt has been made to compare individual cities, all communities that were acceptable for study being compared by groups. When we compare communities which are similar except for their immunization programs, the differences in ampoule distribution are brought out very strikingly. This is shown in Table V for two pairs of communities.

Fall River and New Bedford are perhaps the most closely comparable cities in Massachusetts. Situated less than 20 miles apart, they have almost identical populations, both as to size and racial makeup and both present similar industrial and economic problems. Cambridge and Somerville are adjacent cities of comparable size in the Metropolitan area. Although perhaps they are not so similar to one another as the former pair, they are so similar that the difference in the figures in Table V are of considerable significance. The great differences in the extent of im-

munizations in private practice as measured by the ampoule distribution is hard to explain on any basis other than that the conduct of the public clinics has created a demand for a similar service in the physicians' offices.

Of considerable interest likewise are the figures for the cities of Attleboro and Brookline (Table VI). These are, to the best of our knowledge, the only two of the group studied in which a systematic house-to-house canvass has been made by public health or visiting nurses to urge immunization upon the parents. That they should have shown the highest level of private immunization of any communities studied seems more than mere chance. It might, of course, be objected that Brookline, which is a wealthy suburb of Boston, is hardly a fair selection. The same criticism can certainly not be levelled at Attleboro, which is a strictly industrial community. The conclusion is inescapable that such a program has created an unusual demand for private service even though free service has been obtainable in public clinics.

TABLE VI

COMPARISON OF CLINIC IMMUNIZATION RATES AND AMPOULE DISTRIBUTION IN CERTAIN COMMUNITIES

| | <i>Average Clinic Immuniza- tion Rate per Year per 1,000 Population</i> | <i>Average Ampoules T-A-T Supplied per Year per 1,000 Population</i> | <i>Corrected Average Ampoules T-A T Used per Year per 1,000 Population</i> |

TABLE VII

DIPHTHERIA CASE RATES COMPARED WITH RECORDED IMMUNIZATIONS—ALL COMMUNITIES

| Average Clinic Immuniza- tion Rate per Year per 1,000 Population | <i>Diphtheria Case Rates</i> | | | | | |
|---|------------------------------|-----------|----------------------|------------------|-----------|----------------------|
| | Crude Average | | | Weighted Average | | |
| | 1922-1924 | 1929-1931 | Per Cent Decrease | 1922-1924 | 1929-1931 | Per Cent Decrease |
| Less than 5 | 131 | 105 | 19.1 | 145 | 117 | 19.3 |
| 5-10 | 193 | 104 | 46.0 | 210 | 91 | 56.7 |
| 10-15 | 228 | 82 | 64.0 | 230 | 93 | 59.4 |
| 15-20 | 166 | 54 | 67.3 | 198 | 64 | 67.7 |
| 20+ | 165 | 48 | 70.9 | 193 | 39 | 79.9 |
| State of Massachusetts | 207 | 78 | 62.3 | | | |

Equally significant with the effect of these immunization programs in stimulating a demand for similar service from the family physicians has been the effect on the diphtheria rates. It has been frequently stated that although there could be no doubt as to the value of immunization clinics in preventing diphtheria, statistical evidence on this point was singularly lacking. Some have also advanced the theory that many of the variations listed in the preceding tables might be due to unusual prevalence of diphtheria in the different communities thus creating a demand for private service. In Table VII we have attempted to throw some light upon these two points. Immunization clinics of considerable size began to appear in Massachusetts about 1923 and have been increasing ever since. The diphtheria rate for the years 1922-1924, inclusive, gives, therefore, a fairly accurate measure of the incidence of the disease before immunization had become so extensively practiced as to produce noticeable effects. It also represents the period immediately preceding that covered by the present study. The diphtheria rate for the years 1929-1931, inclusive, represents the situation at the end of the period studied, by which time the effects of the immunization programs should be discernible.

Table VII shows the diphtheria case rates of all the communities grouped as in Table I (35 communities with 2,000,000 population) according to the extent of the immunization programs and the average diphtheria case rates for the two periods.

In Table VIII similar figures are recorded for the selected group of communities studied in Tables II and III.

It is at once apparent that the differences in case rate for the earlier period were entirely fortuitous and determined by chance. They evidently influenced little if at all the relative vigor with which diphtheria immunization programs were to be conducted. On the other hand, the diphtheria case rate for the second period (7 years later) representing the end of this particular study varies directly and strikingly with the intensity of the immunization program. Those cities which have been relatively inactive in providing for diphtheria control through immunization have experienced but slight reduction in case rate, and still are about 50 per cent in excess of the rate for the state at large. Passing from this group through the intermediate groups to that including the cities conducting the most active programs, there is seen a progressive decline in the diphtheria case rate to a level little more than half that for the

TABLE VIII

DIPHTHERIA CASE RATES COMPARED WITH RECORDED IMMUNIZATIONS—SELECTED COMMUNITIES

| Average Clinic Immuniza- tion Rate per Year per 1,000 Population | Diphtheria Case Rates | | | | | |
|---|-----------------------|-----------|----------------------|------------------|-----------|----------------------|
| | Crude Average | | | Weighted Average | | |
| | 1922-1924 | 1929-1931 | Per Cent Decrease | 1922-1924 | 1929-1931 | Per Cent Decrease |
| Less than 5 | 133 | 108 | 18.8 | 156 | 128 | 17.9 |
| 5-10 | 211 | 103 | 51.2 | 222 | 94 | 57.8 |
| 10-15 | 200 | 78 | 61.0 | 197 | 91 | 53.9 |
| 15-20 | 187 | 62 | 66.8 | 205 | 68 | 66.8 |
| 20+ | 184 | 46 | 75.0 | 187 | 47 | 74.8 |
| State of Massachusetts | 207 | 78 | 62.3 | | | |

state. It is hard to draw any conclusion from these figures other than that the diphtheria case rate of the various communities in Massachusetts is directly influenced by the immunization work that has been conducted in clinic and private offices.

COMMENT

In interpreting the foregoing tables it should not be assumed that any one figure has inherent value. At best all of the figures must be mere approximations. Errors may have entered into the recording of children in public clinics. The figures as to private immunization as determined by ampoule distribution are far from precise inasmuch as it is impossible to measure the exact extent to which these ampoules have been utilized. On the other hand, the errors which make these figures little more than approximations are probably fairly constant from one community to another. Inasmuch as the communities are grouped in the various tables the differences in error will to a large degree correct each other. It would certainly be most unreasonable to assume that the errors were all in one direction in communities that had been backward in immunization and in the opposite direction in those that had been active.

Remembering then, that the figures are at best but relative, it is of con-

siderable significance that the trend is so consistent and regular in the various groupings. Table I, which includes all communities over 20,000 (with 3 exceptions noted above) contains the records of several cities and towns which might be challenged. They are included in this tabulation simply to avoid any appearance of so selecting the communities to be studied as to influence the results artificially. It is rather striking that even with the inclusion of these doubtful figures, the trend is so regular and so great.

In the other tables a careful and impartial selection has been made. Only 9 cities and towns have been excluded. The group for study remains so large that the trend which is now even more striking is of unquestionable significance. The same trend is apparent in all the tables. It is the direction and constancy of this trend that is of significance rather than its exact magnitude. The latter will depend on many individual factors and can never be regular for all communities. To the best of our knowledge there is no factor which may have determined this trend other than the different community immunization rates which have formed the basis for the groupings. There appears to be only one explanation for these trends, viz., that the active conduct of a diphtheria immunization clinic program stimulates a demand for such immuni-

zation within the office of the private physician.

It might be supposed that the vast amount of publicity that has been given recently to diphtheria immunization through the newspapers, radio, insurance companies, and magazines for parents would have created such a demand irrespective of a local program. Unquestionably, this has occurred to a slight extent, for during the seven years under study there was a definite though slight increase in demand for private immunization in those communities that have been completely inactive. It is impossible to determine the relative importance of the various factors, or even the extent to which this increase may have been due to an increasing recommendation for immunization by physicians among their patients. These various factors would, however, be constant for all communities, irrespective of the extent of the clinic immunization program. It must be assumed, therefore, that the differences in extent of private office immunization are due to the stimulus attendant upon the conduct of the clinic, and that the stimulus creates a demand on the part of the public for such service in the physician's private office.

Of equal importance with the above considerations are the figures showing

the effect of the clinic programs in reducing the diphtheria rate. It is hard to draw conclusions as to the effect of diphtheria immunization by comparison of individual communities. The age distribution of the children immunized, their uneven distribution over the city in question, and many other factors make such comparisons treacherous and uncertain. On the other hand, when a large number of communities, as above, are studied and the average diphtheria and immunization rates are compared, it is evident that diphtheria decreases as immunizations increase.

CONCLUSIONS

1. The active conduct of diphtheria immunization clinics under official auspices creates a demand for immunization in the office of the private physician.
2. The extent of this demand for private immunization varies directly with the intensity of the clinic program.
3. Without an actively conducted program for diphtheria immunization, the public demand for this service is negligible.
4. Within reasonable limits the incidence of diphtheria in a community varies inversely with the intensity of its diphtheria immunization program.

Children's Code in Costa Rica

THE Children's Code of Costa Rica, enacted late in 1932 by the Congress of that country, announces in its opening paragraph that protection of the mother and child is the function of the State. Practically all the provisions of the code are new in the legislation of Costa Rica. A series of measures on maternal welfare is enumerated in the chapter devoted to that subject; among the measures are provisions for the introduction of ma-

ternity insurance, the establishment of prenatal centers, and the provision of home care and institutional care for maternity cases. The employment of women in industrial and commercial establishments, public or private, is prohibited by this code for four weeks before and four weeks after childbirth. Women in Government service are given leave with full pay during that time; those in private employment are paid one-half of their wages.

The Tuberculosis Movement Today*

DONALD B. ARMSTRONG, M.D., Sc.D., F.A.P.H.A.

*Third Vice-President, Metropolitan Life Insurance Company,
New York, N. Y.*

A BRIEF title to any paper is always an advantage. At the same time it may be misleading. Certainly we are not attempting here a comprehensive or exhaustive analysis of the tuberculosis movement today. Rather, we shall endeavor to point out a few of the more conspicuous features of this program, a few of the principal points of emphasis, with their indications as to how effort may be most promisingly applied in the immediate future. Certain comparisons between the situation today and that of a decade or two ago may also be of significance.

A glance at the tuberculosis program of 15 or 20 years ago, in the light of our interests and objectives today, brings out certain contrasts and certain similarities. In the first place, it is evident that some of the attitudes and slogans of the early period still hold good, though occasionally with a difference in interpretation.

Sixteen or 17 years ago, when the Framingham Tuberculosis Demonstration was initiated, certain experience in connection therewith crystallized in the statement, "The next step in tuberculosis work is the first step, namely, find the cases." To a large extent that is still true today, as evidenced by our Early Diagnosis Campaigns and similar projects. There is, however, some difference in approach. Then, we were mainly in pursuit of the adult, and of the active case, in order to get him into

the hands of the physician, to provide a clinical examination, to arrive at a diagnosis and to secure proper treatment. We are now much more interested in and hopeful about tuberculous infection. We are also much more interested in childhood. The basis of our attack has broadened. We are endeavoring to break the tuberculosis chain further back in the chronology of the typical case of disease. We are interested not only in the active case, especially in young adults, and more particularly in females, where the rates are relatively high, but in infection, and in the so-called latent case in childhood, with the earliest signs of invasion.

We have become aware that roughly speaking there are 3 and sometimes 4 principal periods or episodes in the typical case of tuberculosis: infection, latent childhood disease, perhaps reinfection, and active adult disease.

This change in point of view comes about through our acquisition of greater knowledge of the epidemiology of the disease. The science of epidemiology is at last being effectively applied to the problem of tuberculosis. Our point of view concerning the incidence of tuberculous infection has more or less radically changed. There may have been a time in urban populations when tuberculous infection was practically universal, but this can no longer be assumed. It is true that in certain rather selected urban groups its incidence is still high. Hetherington still finds 90 per cent of adolescent school

* Read before the Annual Meeting of the Indiana Tuberculosis Association in Indianapolis, Ind., April, 1933.

children or pre-adults with positive tuberculin tests in Philadelphia. It is believed, however, that a more representative finding is that reported from Massachusetts where the average for many communities among children between 5 and 15 years of age is 28 per cent. Incidentally, when these are examined by X-ray, 5 per cent show some damage, usually slight, and in about 1 per cent this is serious enough to require continued medical attention. Instances of the opposite extreme in positive tuberculin findings are reported by Broker, in Minnesota, where only 1 in 160 girls and boys was positive, and by McCain, in North Carolina, where only 4 per cent were positive. It may be remembered that in 1917 in Framingham a group of younger-aged school children showed 33 per cent with positive tuberculin reactions. Ten or 12 years later, after the Demonstration, a considerably older school age group showed only 18 per cent positive. These two sets of tests were sufficiently similar in technic to be legitimately compared, even though differences in method may in part account for some of the wider variations among recent findings cited. It would therefore appear that the prevalence of tuberculous infection is diminishing and that it is controllable. It is no longer necessary to assume that infection is inevitable. It is possible to find the foci of infection, whether human or animal. It is worthwhile, therefore, to stress the point that every tuberculosis case comes from another. The search for family foci in particular is profitable. The examination of contacts is advantageous both from the angle of discovering a source of infection and also from that of disclosing possible channels for further dissemination.

All of this represents a rather striking change in point of view—a new attitude that is perhaps the principal feature of the tuberculosis movement

today. The discovery of the child in tuberculosis promises to be a very great contribution, not only to the welfare of children but also to the problem of tuberculosis control at large. This approach has stressed the intensive use of relatively new instruments in the wholesale search for the disease. Fluoroscopy as a screening process, and the use of the tuberculin test with the X-ray have very advantageously supplemented the older clinical procedures. The use of these diagnostic devices tends to become universal among the younger age groups, only the question of cost standing in the way. Here the situation is promising. Experiments are indicating the feasibility of these procedures on a large scale. For instance, the Queensboro Tuberculosis Association in New York, with the coöperation and financial aid of the Metropolitan Life Insurance Company, has been experimenting with the Powers portable rapid X-ray camera and paper films, demonstrating the possibility of making as many as 1,000 chest exposures in a day, at a per capita cost somewhere in the neighborhood of \$.75, including the expense of interpretation. Experiments elsewhere indicate a cost possibly as low as \$.40. In normal times many communities would not find this too great a burden to add to the routine school health and medical examination procedures.

It is true that there is as yet no universal acceptance of the significance of so-called latent tuberculosis in childhood, as to its hygienic or therapeutic indications in all cases; yet on the whole the outlining and defining of this phase of the manifestation of tuberculosis seem to represent a big advance in our concept of the disease and in our methods of detection and control.

In the meantime, while human foci have been more and more frequently detected and eliminated, much progress has also been made toward the elimina-

tion of animal foci and the control of the hazards of tuberculous milk. It is well to realize the progress made in these directions and the necessity for maintaining the position now held. A relaxation in our efforts at control may be costly. One cannot but experience misgivings when one notes serious curtailments, for instance, in appropriations for health department epidemiological activities, or for institutional care of open cases of the disease. It is not reassuring to read of the organized opposition to the tuberculin testing of cattle in Iowa and elsewhere. We are here faced with the dangers of losing the advantages gained in the past, and of restoring certain of the largely eliminated hazards of childhood. There might also readily be incurred serious economic consequences to individuals and families, to the cattle and dairy industries, and to our communities generally.

Still in the general field of epidemiology, it is regrettable to note that while great steps in advance have been taken along the above mentioned lines, little progress has been made toward the artificial immunization of humans against this disease. The Calmette vaccine is, of course, being widely experimented with. Certain observations reported by foreign experimenters seem promising but are accepted with reservations here. European statistics concerning the effectiveness of the vaccine are viewed with doubt by statistical authorities in this country. Perhaps the most basic work in the field is being done by Park in New York, with the coöperation of the Metropolitan Life Insurance Company and other agencies. Here the vaccine is being used with careful controls, and with results that are considered encouraging. However, most authorities feel very definitely that this procedure occupies a controversial position and cannot as yet be endorsed for routine or wholesale application.

On the other hand, more strictly in the field of treatment, but of public health as well as therapeutic significance, it is very encouraging to note the increasing success with which the lung collapse, rib resection, and other forms of thoracoplasty are being employed—procedures that with increasing frequency are proving advantageous to the patient, as well as helpful in decreasing human foci of infection. These certainly represent outstanding advances in treatment methods of the present and recent past, and may be of sufficient significance to account in part for the continued improvement in tuberculosis mortality.

This suggestion seems to be borne out by available records. As is well known, in the treatment of advanced cases with extensive cavitation prior to the days of thoracic surgery, the early mortality following diagnosis was extremely discouraging. In a study by Sprungmann, based on 626 cases, there was found a total mortality of 78.2 per cent in 16 years, and a death rate of 61.7 per cent in the first 2 years. Barnes and Barnes, in 1,450 cases, found a mortality of 80 per cent within 1 year, and 90 per cent within 5 years. In contrast to this, as Fischel recently pointed out, a study by Neuberger based on cases treated with thoracic surgery indicates that after 1 to 5 years, over 61 per cent had regained and retained their working and earning capacity, and only 17 per cent had died, the remaining being in the incapacitated group. Chadwick, from the experience of the Herman Kiefer Hospital in Detroit, referring to the period 1929 to 1932, states that "The number discharged with favorable results has increased from 45 per cent to 69.8 per cent, and the number of deaths has decreased from 25 per cent to 6.5 per cent. The marked reduction of deaths and the improvement in discharged patients have been due in a large

measure to the general use of collapse therapy." When one realizes the increasing extent to which this great contribution to tuberculosis therapy is being applied by institutions throughout the land, the above assumption concerning its probable relationship to mortality seems justified.

On the statistical side we are all aware of the progress that has been made as measured by the death rate from tuberculosis. With the disease now ranking 7th or 8th, we have come a long distance since the time when it occupied the first position as cause of death. However, it must be recognized that mortality is by no means a complete measure of the situation. Furthermore, deaths at all ages are sometimes not as significant as deaths in particular age groups, as has been frequently pointed out. This is especially true of tuberculosis, which still stands first as the cause of mortality and disability in the productive period of life from 20 to 40 years. Nevertheless, the mortality rate presents a gratifying picture. Among Metropolitan industrial policy holders, who constitute a group of many millions, the death rate for 1932 reached 70.1 per 100,000, contrasted with 114.2 in 1922, and 224.6 in 1911. This improvement in 1932 seems to have been characteristic for the country at large, so far as records are available. Here in Indiana, with the rate of 88.1 in 1922, and 61.1 in 1931, the rate was 59.9 in 1932, which represents 16 fewer deaths than in 1931. In the Metropolitan experience the drop in 1932 is 8.6 per cent under the previous year, which is the biggest percentage annual decline in a decade. Thus far, 1933 seems to be reflecting this downward trend, the cumulative rate to date being 66 as compared with 69.2 in 1932. There seems to be no reason as yet to doubt Dublin's earlier forecast of a rate of 40 for Metropolitan industrial policy

holders by 1939, and a rate that may fall between 28 and 37 per 100,000 for the original registration states by that year.

On all hands considerable surprise has been expressed that there has been thus far no effect upon the death rate coincident with the depression. While this is evidently a fact, of course no one can yet estimate the ultimate effects of the depression, and no one can say what may or may not follow the underfeeding and malnutrition and other physical and mental characteristics of the depression period, especially as they bear upon childhood. Certainly undernutrition is by no means negligible, as shown by the fact that in New York City alone, in 1932, 32 deaths were reported by the Division of Medical Records as resulting from starvation, including no cases of refusal to eat, inability to eat, or cases of deficiency disease. The prospects are considered by many to be disturbing, yet thus far, in addition to the mortality picture, there have been reported no very significant or definite signs of an increase in the incidence of latent or active tuberculosis in any age group.

Indeed, 1932 was the best year thus far in the general mortality experience of Metropolitan industrial policy holders, and probably also of the population at large. It seems probable that a combination of circumstances may be responsible for this favorable situation. In the first place, health departments and voluntary health agencies have operated effectively, even with curtailed resources. In the second place, relief, even though on a minimum basis in many communities, has nevertheless been organized and administered with thoroughness. In the third place, our public at large was fairly well informed concerning disease prevention and health conservation, and has drawn upon the reserve of education built up

in the pre-depression years, contributed to by public and private agencies alike. Finally, and perhaps most important, climatic and epidemic conditions were most favorable during 1932. In particular, we were relatively free from outbreaks of acute respiratory disease, particularly influenza. When influenza and pneumonia incidence and mortality are low, deaths from other causes, including tuberculosis, tend to remain at a minimum. By way of contrast, we have the experience of 1918, and indeed the minor influenza outbreak in the early part of 1933, when deaths from many causes showed a tendency to increase, although, fortunately, this set of circumstances in this latter instance has appeared not to have affected the tuberculosis mortality to a serious degree.

Looking back over the remarkable decline in tuberculosis mortality in the last several decades, it must of course be admitted that many forces and factors have been at work, including economic and social improvement, general sanitation, occupational hygiene, etc. Nevertheless it has been definitely established that the antituberculosis campaign in which we have all been engaged has contributed materially to this very concrete accomplishment. There is every reason to hope that the campaign, if continued along present lines, with such modifications in emphasis as new knowledge and circumstances may dictate, will lead us—providing we meet with no serious setback such as might be associated with the sequelae of the depression—to man's ultimate conquest of tuberculosis that will place this disease, alongside of typhoid fever, yellow fever, and diphtheria, in the

museum of fast disappearing causes of death.

Hopeful signs that augur well for the future are the coöperation of forces and the integration of effort that seem to be more and more characteristic of our general health program. There is, I believe, a greater mutual understanding of aims, and mutual aid between health and medical organizations than ever before. This applies to tuberculosis associations, to physicians, to health officers, and to civic and industrial units. The leadership of health authorities is becoming more conscious, more liberal and more constructive. Our present joint efforts to maintain appropriations and personnel for public health work are an encouraging sign of the times. In addition, as stated above, the public is better informed than ever before, as a result of the activity of such organizations as the Indiana Tuberculosis Association.

All this leads us to hope that in spite of the present serious handicaps, we may be successful in holding the gains of the past, in experiencing only a temporary curtailment in our resources, and in making a wisely balanced use of such facilities as we now have for the promotion of the most essential services. We can also hope to see the most effective integration of the tuberculosis movement into the general health program, recognizing its relation to administration, to sanitation, to education regarding nutrition, health examinations, and similar health promotive activities in the field of personal hygiene. The realization of those hopes, in which I know you all share, will carry forward the control of tuberculosis to a triumphant termination.

Smoke Abatement at Low Cost*

MORRIS M. COHN, M.Sc. IN C.E.

Sanitary Engineer, City of Schenectady, N. Y.

HEALTH activities are no more immune from amputation than are the municipal markets or the ornate fleets of limousines. Old services fight to endure. New services are whispered about behind closed doors and then pigeonholed to await a more auspicious day of birth. It is in such a world of indefinite values that the infant, Smoke Abatement, finds itself.

The whole problem of air hygiene is comparatively new in civic progress. The cities that have pioneered in smoke abatement have merely scratched the surface of the difficult task. In many cases, smoke abatement laws were enacted during the days of municipal munificence, and even then enforcement of the new regulations was made impossible because of lack of organization. In the present financial stress, a new service like smoke abatement is likely to fare poorly. Many cities not engaged in atmospheric cleansing will find themselves with the vehicle of air hygiene and no motive power, while for those proposing the inauguration of smoke abatement campaigns, there is discouragement ahead.

Even the most ardent proponent of smoke abatement will admit that the most rigid anti-smoke ordinance, the most intelligent boiler installation control, and the most vigilant smoke detection cannot produce an unhazed skyline. What is first needed is a smoke-conscious citizenry. To whom does

smoke abatement appeal? The general public? They can get little satisfaction from the statistical fact that their city's smoke costs each citizen \$15 a year, when they know that every dollar they have had in the past year has gone for food and clothing—the bare necessities of life. The merchant? The argument that smoke ruins his merchandise falls upon deaf ears when he realizes that business is poor and the most frequented spot in his shop is the bargain counter of soiled goods. The property owner? While the smoke official recounts the sooting effects of smoke and the destructive action of stack fumes, he is mentally computing his tax bill and wondering where he can raise the money to pay it. The ultraviolet ray addict? He is too busy basking in the radiance of his sunshine lamp and eating irradiated foods to worry about the sun-robbing effects of smoke.

Who else? The building superintendent? While he listens to the scientist explain that smoke means poor combustion and money wasted, he is deciding to buy a cheaper grade of fuel and use the porter for fire stoking, thus enabling him to discharge the expensive fireman. The civic leader? Talk to him about the dangers of the smoking factory stack and he raises his hands heavenward and fervently prays for more smoking industries.

This is rather a pessimistic picture for a smoke abatement proponent to paint. Fortunately, the pitfalls have been exaggerated for the sake of emphasis.

Smoke abatement efforts must not

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

cease, even in the face of depleted budgets. There are certain services which must be provided whether the public wills it or not. Smoke abatement is one, though it is less recognized as a health policy than are the others which control environmental conditions. A let-down in this work may destroy much of the progress made by the pioneers. It is the duty of existing agencies to keep going, somehow, some way, until financial conditions permit other cities to take up the work. Now is the time for all sanitarians to talk price; bargains in smoke abatement will become mighty popular.

SCHENECTADY PLAN

It is interesting to review the smoke abatement policy of Schenectady, N. Y. The control methods and accomplishments of that community's campaign are worthy of attention, not as examples of what a good smoke abatement program should be but what it has to be to meet present financial conditions.

Schenectady, a manufacturing city of 97,000, has regulated its growth in accordance with a zoning code since 1927. In setting forth the areas available for certain types of commercial and industrial activity, the zoning law designated 3 zones of unrestricted manufacture, these being in the areas occupied by the General Electric Company and the American Locomotive Company, the two leading industries.

The original smoke ordinance went into effect in 1927. It contained all of the approved provisions. Smoke of greater density than No. 3 on the Ringelmann chart was not permitted for more than 75 seconds of any one hour, except when fires were being started or cleaned. A 6-minute smoke production was permitted per hour under such conditions. The 3 zones of unrestricted manufacture were designated as zones of unrestricted smoke, no control being maintained over the

industries. Smoke was restricted from all structures, tugs, locomotives, rollers, etc., but smoke from any residence was not a violation of the law. The Bureau of Engineering was designated as the enforcing agency. Smoke production became a misdemeanor subject to fines of from \$10 to \$100, each day of smoke production being a separate violation. Permits were required for the installation of new boiler equipment or major repairs to existing units.

For a period of a year and a half, Schenectady found itself with a cumbersome ordinance, difficult to enforce in its entirety, and without a staff to serve as the enforcing agency. One man, a heating engineer, was charged with the task of reviewing plans for boiler installations, inspecting installations for conformity with the plans, issuing permits, and observing smoke violations. In his spare time he designed the heating and ventilation systems for a rather extensive group of city buildings then under construction. Even sweet Charity could class this type of smoke abatement as nothing more than a low-class activity at low cost.

In 1928, a simplified abatement ordinance was adopted, the old one being retired from the books. It made no provision for control over boiler installations or repairs. Smoke from residences was brought under control and all other smoke provisions of the old ordinance were retained.

It is characteristic of the general bargain-hunting spirit that the enforcement of the new ordinance was again delegated to one man, the writer, who served as engineer of sewage treatment and director of the city's material testing laboratory, and utility man on general municipal sanitation problems. Located at the treatment works—and all sanitarians know where that is in relation to the business district—the smoke abatement official was in a

poor position to act as a smoke spotter. The work consisted of investigation of specific smoke complaints, observation of points of potential smoke production as time permitted, and a slow methodical all-city survey of stacks that was planned to take 6 months. A program of friendly contacts with smoke violators was inaugurated although little time was available for the study of troublesome installations for the purpose of improving combustion.

In this campaign of hit-or-miss smoke control, some improvement was noted. What benefits were reaped, however, were neutralized by the general dissatisfaction produced by the sporadic activities. The one-man campaign was filled with embarrassments for the municipality. A call upon the owner of a smoking stack was certain to end in a denunciation of a policy that attacked his humble building and left dozens of others to go scot-free. Each violator could enumerate an imposing group of other violators; it was impossible to obtain coöperation under such conditions. Furthermore, persistent complaints from some neighborhoods could not be verified by the inspector in the short periods he could devote to the nerve-racking job of watchful waiting. It became whispered about among a group of disgruntled housewives that the inspector was in league with the owner of a troublesome laundry and that no smoke would ever appear until the official took his leave. This group took pictures of the smoke from this stack and presented the evidence to the writer with ill-concealed sarcasm.

Here is a lesson for any community that proposes to set up a one-man organization to control smoke, unless that man becomes a mere spotter located in a crow's-nest with field glasses trained upon the sky-line. No active campaign can be waged until the smoke abatement organization comes out into the

open to wage battle and offer assistance to property owners. It can be established as an axiom of smoke abatement that "the more visible the staff, the more invisible the smoke."

It became evident in Schenectady that smoke abatement would die a well-wished death unless violators were assured that stack control was universal rather than individual. This required an increased staff. Even in the more generous days of 1930, no funds for this purpose were forthcoming. It was found, however, that the Fire Prevention Division of the Fire Department was doing work akin to smoke abatement. The inspectors of this division were checking up on oil burners and were often instrumental in obtaining stack extensions made in the interests of safety.

An appeal to the Commissioner of Public Safety met with willingness that the Fire Prevention inspectors should assist in the smoke abatement program in the capacity of smoke inspectors. At one stroke, a non-technical inspection force became available at no cost to the city. This group, while unversed in smoke abatement procedure, was especially well trained in city inspection work. The unit consisted of a fire marshal, an assistant fire marshal, a chief inspector and 6 inspectors. These men had been chosen from the Fire Department when the division was formed. The city had been divided into 6 districts ranging in size from small areas in the congested business section to larger areas in the outlying sections. One inspector was put in charge of each district, the business and secondary business territories being covered by the inspector daily and the residential sections every 2 to 4 days, depending on the locations. Each inspector knew his territory "like a book," and knew likewise the owners of the principal business and commercial establishments like the characters in that book.

Here was an inspection force that with proper training could be made into a splendid smoke detection staff. A course of instruction was arranged. At a series of informal chats, the firemen were informed about the dangers of smoke, the abatement activities of other cities, and what could be expected in their own city. A non-technical explanation of the theory of combustion was also presented. A special effort was made to show the relation between the improper combustion conditions that produce smoke and fire hazards. The men were taught to gauge smoke densities by means of the Ringelmann chart and every opportunity was taken to point out smoke from the windows of the lecture room and have the men guess its color density. A splendid picture of a No. 3 smoke was duplicated and a copy mounted in a pocket folder presented to each inspector for use during the training period.

The men were sent out for a probationary period of smoke observation, during which they made notations of all smoke observed, regardless of density or period of duration. The men entered upon the work with vim and derived great pleasure from their new accomplishments. Within a short time the firemen were sufficiently acquainted with their tasks to warrant placing them on the streets as official smoke inspectors. For almost 2 years, these men have vigilantly observed all smoke violations in the city. They have done their work well; it is a mighty infrequent smoke plume that gets by the inspectors.

All smoke violations are recorded on small report forms of file-card size which are turned in to the fire marshal each day. The firemen are instructed to call the attention of each violator, as quickly as possible after the smoke is observed, and to urge remedial measures. No technical advice is offered. If the property owner asks for advice, the case

is referred to the engineer who calls upon the owner and makes suggestions for improved combustion. Where possible, the firemen or the chief inspector is in attendance at this time and he attempts to check up, during subsequent inspections, to determine if the advice is being followed.

Weekly conferences are held during the heating season, at which the engineer and the inspectors discuss the findings of the previous week. If any inspector has experienced trouble with a violator, the case is discussed. It is interesting to note that other inspectors usually know the individual and something of his property and can offer suggestions on how the person can best be handled. Letters are frequently addressed to such violators, suggesting in a friendly vein that steps be taken immediately to correct the smoke violation. A copy of the smoke law is attached. Similar letters are sent to those violators not visited by the inspectors.

Several innovations have been introduced in Schenectady for the purpose of making possible the low cost control. The city has made an appeal to all coal dealers handling bituminous coal to supply their customers with the lowest volatile fuel consistent with their price limitations and combustion conditions. Several installations have changed from bituminous to small-size anthracite coal as a result of this activity. Others have changed to non-smoking types of bituminous fuel, and smoke conditions have improved as if by magic.

A coöperative campaign was waged by the city and the fuel economy officials of the two railroads that serve the community. One line went to the expense of posting notices of Schenectady smoke regulations at their division points and having their locomotive inspectors obtain the signature of each engineer and fireman to a statement that they had seen the notices.

Several careless firemen and their engineers were called before the superintendent and reprimanded. As a result, the locomotive that stands at the station and paints the city with a bituminous brush is the exception.

No control is maintained over the installation of new or the repair of old fuel burning equipment. The Schenectady policy has been, "If the stack is right the boiler must be right." Discontinuing this control with the enactment of the new smoke ordinance has made enforcement much simpler. At the same time, it has removed but little of that valuable regulation which the city previously had over the equipment that was to make smoke in the future. In the case of Schenectady, little new boiler work was being carried out and that being done was a small portion of the total fuel burning equipment in the city. Since no control was possible over existing equipment, the loss of control over new units was not a serious matter. More important, however, is the fact that the city has maintained an invisible control over new boiler work, without actually seeming to do so. It has become customary for property owners, architects, and contractors to require the boiler manufacturers to

guarantee that their equipment would comply with the existing smoke law. Requests for copies of our ordinance are often received from manufacturers.

The Schenectady plan is full of corner-cutting schemes, which, I fear, will not endear it to the hearts of those who take air hygiene as a scientific problem for scientists. The inspectors are not technically trained to solve combustion problems. Their findings cannot, therefore, be used to force compliance with the law by strong arm methods. The Schenectady program is planned, of necessity, to be politely persistent rather than belligerently bossy.

The low cost smoke abatement plan is not an aggressive, speedy method of giving a community its place in the sun. It can, however, provide the means of keeping an existing program from complete extinction and may even enable new cities to inaugurate atmosphere sanitation in the face of economic odds. The Schenectady plan makes use of a fire prevention inspection staff. Other cities may make use of some other official or non-official group. The keynote of successful smoke abatement is coöperative effort. It is on the foundation of concerted effort that low-cost smoke abatement can be built.

German Health Center for Mental Disorders

A HEALTH center for mental and nervous disorders, excluding feeble-mindedness, is functioning in a suburb of Berlin. The work of the center is concerned with both adults and children. Some children are brought voluntarily by their parents, but the great majority come from the public schools, the Children's Bureau of Berlin, the child health centers, and other welfare agencies. At the child health centers, all children above the

age of 3 are examined as regards language, habits of cleanliness, and behavior while at play, and those deviating from normal are referred to the center for mental and nervous disorders, where the necessary treatment is provided. In this way it is hoped to introduce a general system of psychological testing of young children in order to detect early any deviations from normal. — *Gesundheitsfürsorge für das Kindesalter*, Berlin, 7, 6, 1932.

Bacterial Content of Frosted Hamburg Steak*

LAURENCE P. GEER

Massachusetts Institute of Technology, Cambridge, Mass.

WILLIAM T. MURRAY AND ERNEST SMITH

Birdseye Laboratories, Gloucester, Mass.

THE increasing popularity of foods preserved by the quick freezing process is causing attention to be focused upon the numbers of bacteria which may be expected in such foods. How does the total count compare with the total count of food of the same kind and grade unfrozen? Will the freezing process and subsequent cold storage kill an appreciable number of the bacteria originally present?

In the case of fish products, Birdseye¹ has shown a marked reduction in total numbers during the process of preparing, freezing, and storage. Berry² has shown a reduction of 90 to 99 per cent in berries after freezing and storage, for 1 year at 15° F.

This paper is concerned with hamburger steak, since this product is subjected to considerable manipulation, and is known to yield a high count of bacteria.

Several investigators studied the plate count of hamburger steak as an index of its sanitary quality. Marxer³ suggested that a sanitary limit of 1,000,000 bacteria per gm. be set, but in 1914 Weinzirl and Newton⁴ found this standard too low and suggested 10,000,000 as fairer. In 1917 Lefevre⁵

made counts on 22 samples of hamburger steak in Washington, D. C., and his results checked closely with those of Weinzirl and Newton, but he concluded that 1,000,000 bacteria per gm. was not an unreasonable limit.

The present investigation includes counts upon 10 samples of fresh, unfrozen hamburger steak as bought in the markets, and 10 samples of Birdseye Frosted Hamburg Steak, bought from retail stores. The frosted hamburger steak was purchased in 1 lb. Peters type cartons in which it was offered for sale. The cartons were not opened until they reached the laboratory, but in each case the contents were still solidly frozen when opened.

The unfrozen hamburger steak was bought in clean, first class meat markets. In the case of 7 of the samples the meat was removed by the market attendant from an already ground batch on display in a refrigerated case. The other 3 samples were ground at the time of purchase. The purchaser of the meat in each instance insisted upon "highest quality."

The purchases were all taken to the laboratory as quickly as possible and sampled within 1½ hours. For each specimen of hamburger steak, 3 check samples were taken from different portions of the mass. Six plates were

* Read before the Food and Nutrition Section of the American Public Health Association, at the Sixty-first Annual Meeting in Washington, D. C., October 22, 1932.

counted for each of the 3 check samples, and the average was taken as the count for that particular sample. The average of the counts of the 3 samples was then taken as the count for the batch of hamburger purchased, making an average of 18 plate counts for each figure given in the tables which follow.

In the literature reviewed no reference to a standard method was found, and little was said of the method followed. It is evident that in work dealing with materials of the class here reported on, the technic of preparing the sample is of utmost importance. The more thoroughly the tissue is disintegrated, and the clumps of bacteria broken up, the nearer the plate count will approach the actual number of living organisms present. This will mean, with the present technic, a somewhat higher count than some of those recorded by earlier observers. The procedure adopted in the present investigation was originally described by Dr. P. K. Bates, director of the bacteriological laboratory of the Frigidaire Corporation, and modified by the authors in conjunction with H. C. Needle of the Massachusetts Institute of Technology. It is as follows:

Ten c.c. of a rather coarse white sand (20-40 mesh), and 90 c.c. of distilled water are placed in a 300 c.c. Ehrlenmeyer flask, which is then plugged and sterilized, and, before using is cooled to 35° F. The plug is removed, the neck flamed, and the flask weighed. Approximately 10 gm. of the sample are placed in the flask, which is then reweighed. All weighings are made to the nearest 0.1 gm., and the calculations are made upon the basis of the actual weight of the sample. The hamburger steak should be thoroughly mixed with a sterile spoon, and the samples added to the flask with sterile forceps, picking pieces from various portions to obtain a representative sample. The flask is

then tightly closed with a sterile rubber stopper and placed in a refrigerator at 35° F. for 1 hour. Experimental evidence has shown that bacteria will not increase materially at that temperature during this period, and the water works its way into the interstices of the meat, weakening its structure and allowing better maceration upon shaking. The flask is then placed in the shaking apparatus, which has a stroke of 6 inches (1 foot per revolution) and makes 180 revolutions per minute. The flask is shaken for 5 minutes, after which it is removed and allowed to stand for 5 minutes. During this time the sand and larger particles separate out, but most of the bacteria remain in suspension, and the solution can be pipetted readily.

The solution in the flask is now considered 1:10 dilution: that is, the number of bacteria per c.c. is 0.1 of the number per gm. in the hamburger steak. Dilutions 1:1,000, 1:10,000, 1:100,000, and 1:1,000,000 were made as a routine, and plated upon Difco nutrient agar. All plates were incubated at 25° C. for 72 hours.

The results of the examinations are shown in Tables I and II, and show a definitely smaller number of bacteria in the frosted hamburger steak than in the fresh. No sample of the frosted hamburger steak showed a count as high as the lowest of the fresh, and the average count of the frosted is 89 per cent less than the average of the fresh.

The above facts led to a consideration of why the frosted meat contained relatively so few bacteria. Ten packages of the unfrozen hamburger steak were obtained from the establishment which had packed the frozen samples used in the first experiment. From each of the 10, 3 samples were taken according to the method described, the packages were then frozen in a Birdseye multiple plate froster, according to regular commercial procedure, and 3

TABLE I

TEN SAMPLES OF UNFROZEN HAMBURG STEAK

| Market | Bacteria per Gram |
|-----------------------|-------------------|
| No. 1 | 24,300,000 * |
| 2 | 43,700,000 |
| 3 | 6,000,000 |
| 4 | 6,700,000 |
| 5 | 18,300,000 |
| 6 | 16,200,000 |
| 7 | 8,500,000 * |
| 8 | 10,100,000 * |
| 9 | 27,100,000 |
| 10 | 20,100,000 |
| Average of 10 samples | 18,100,000 |

* Freshly ground at time of purchase.

samples again taken from each package. A third series of 3 samples was taken after 1 month's storage at 0° F. The results are given in Table III.

The quick freezing process causes a material reduction in the numbers of bacteria and, in general, the greatest reduction comes in those samples having the highest initial count. The per cent reduction varies from 66.6 to 87.9 per cent, the average being 79.5 per cent. A subsequent period of storage of 1 month at a temperature of 0° F.

TABLE II

TEN SAMPLES OF FROSTED HAMBURG STEAK

| Dealer | Bacteria per Gram |
|-----------------------|-------------------|
| No. 1 | 1,100,000 |
| 2 | 2,600,000 |
| 3 | 2,400,000 |
| 4 | 1,500,000 |
| 5 | 2,400,000 |
| 6 | 3,200,000 |
| 7 | 2,100,000 |
| 8 | 2,300,000 |
| 9 | 1,900,000 |
| 10 | 700,000 |
| Average of 10 samples | 2,000,000 |

still further reduces the numbers of viable bacteria, the average reduction under these conditions being 24.5 per cent. The over-all average reduction due to freezing plus storage for 1 month is 84.1 per cent.

A sanitary standard considerably below 10,000,000 per gm. seems warranted for this type of product, and bacteria counts of properly frosted and stored hamburger steak may be expected to be consistently lower than those of the best grade of the fresh product for sale in high class meat markets.

TABLE III

BACTERIAL COUNT BEFORE AND AFTER FREEZING, AND AFTER ONE MONTH'S STORAGE AT 0° F.

| Sample No. | Bacteria per gm. | | Per Cent Reduction | Bacteria per gm. | | Per Cent Reduction | Total Per Cent Reduction During Freezing and Storage |

The Doctor and His Business

NO, the doctor in the past has not been good at business and most of those who happen to possess that talent soon leave the profession for fields where they more properly belong.

Why he should refrain from forcible collection of his unpaid bills; why he does not patent some of his prescriptions, inventions and discoveries and make a fortune; why he should continue to counteract the spread of diseases he has painfully and at great educational expense learned how to diagnose and treat; why he should so strenuously oppose year after year the efforts of antivivisectionists and antivaccinationists with their Christian Science allies to cripple research and to annul statutes already on the books, knowing his calls would increase did they have their way; and why at the same time he should continue to work longer hours for less pay during a shorter life of activity than most people is an enigma to a hard-headed business man.

To be sure, business is now recognized as one of the professions in certain educational circles, but whether this will elevate the ethics of business which is fundamentally competitive

rather than fraternal, or whether it will undermine the code of medicine remains to be seen. . . .

And since everyone is doing it, how long will the doctors continue as a class to resist? When they no longer do, and adopt the advertising methods of those parasites of the profession, the quack and the patent mediciner, God help the man of modest means and everyone else, whether below him or above him in the social scale, who may some day need a doctor.

The explanation of the doctor's seeming want of business acumen lies partly in the restraining influence of his time-honored precepts of conduct, partly in his preference to hold the respect of his own kind rather than of the financial world, and partly because inherently he's that kind of person else he wouldn't have gone into medicine in the first place. He's already done a great deal not only for the poor, but for the man of modest means as well, and it is offensive to be told by a board of lay people that he's neglecting them.—Harvey Cushing, M.D., Medicine at the Crossroads, *J.A.M.A.*, May 20, 1933, page 1571-72.

A Plan to Obtain More Accurate Records of Infant Hygiene Field Work*

C. A. SARGENT, M.D., F.A.P.H.A.

*Director, Division of Child Hygiene, Delaware State Board of Health,
Dover, Del.*

WHEN a study of the causes of high infant mortality in Delaware was undertaken it was found that the nurses' records were of little value as a source of information. This was due to lack of uniformity, omissions, and masses of meaningless data.

All nurses were interviewed individually regarding the method of recording. In most instances it was their opinion that the records were used as a check-up on the amount of work done rather than the type of field work or the conditions found. For the most part, they had only a vague idea of the number or causes of infant deaths, the number of breast or bottle fed babies, and, with the exception of a few outstanding cases, the conditions in general.

Formerly the plan of operation was as follows. A state law requires attendants at birth to report the birth by post card within 24 hours. From the post cards a list of births in each nurse's district was made up and sent to that particular nurse. This was done before the attendant had issued the birth certificate. From 2 to 6 months later the birth certificate would be sent to the nurse for delivery. The original object in issuing the birth certificate by means of the nurses was to give them a means of entry into the homes, yet by the above mentioned plan the nurse had, in

many instances, visited the home so that the delivery of the birth certificate reverted to the plan of taking a day or two each month simply to go from one home to another to leave the certificate.

In 1930 a different plan was adopted in one county and extended to the entire state in 1931.

The program now in vogue is as follows: All original birth and death certificates go directly to the office of the director of the division of child hygiene. As soon as they are received, the birth certificate is issued, a 5" x 8" child record card for each birth, and an infant death card for each death under 1 year of age and each stillbirth, are typed. All are sent directly to the particular nurse from whose district the reports were received. The clerk in the county unit files the birth cards in the nurse's file. Printed paper duplicates of the child record cards are supplied on which the clerk types the information from the original cards. These duplicates and the birth certificates are given to the nurse. The certificate is delivered when the nurse makes the home visit, and while in the home the nurse writes all data on the duplicate record. These records are then given to the unit health officer who inspects each one carefully to see that the necessary information is given and makes a note on the record when the case is to be seen again, at which time another duplicate record form is given to the nurse. The clerk types the information on the

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27, 1932.

At times the nurses find unreported births. When this occurs a duplicate birth record sheet is made out, and from this an original card, and from the original record a request is forwarded to the State Board of Health for a certificate. The State Board of Health then sends a request to the attending physician for the birth certificate. This is an additional reason for having the father's and mother's names as well as the child's name, and address of the family, "registered" and "attendant" included on the record card. Under "Remarks" the nurses have been instructed to include conditions in the home, coöperation, financial conditions, and all things which in their opinion have direct influence upon the health of the child.

The nurses also include such information as suspected or known cases of tuberculosis, so-called children's diseases, prenatal cases or unreported births in the home or in homes closely adjacent.

The age of the mother is included because a study of the records for the past few years has been carried on to determine whether age of mother at child birth is changing. It is obvious that many items have been omitted. An attempt has been made, however, to obtain as much information as possible having direct bearing upon conditions as found, with a minimum of clerical work.

Several things have been accomplished. The nurses, unit health officers, and the director of child hygiene now have a better idea of conditions existing in each nurse's district. More accurate records are being kept. The infant mortality rate is calculated for each district and causes of infant deaths are discussed with each nurse and a definite program is being formulated. Several unreported births have been found. Without additional personnel, information is being obtained

pertaining to other phases of public health work. Efforts are being made to establish more prenatal and venereal disease clinics.

For the first 6 months each nurse was required to visit the home of every baby twice before the child was 6 months of age, to give the unit officer an idea of conditions. Recently the program has been revised so that to wealthy families the certificate and literature are sent by mail, and the nurse is not required to visit the home unless requested to do so. The nurse visits the homes of the families of moderate means once, at which time she determines whether it is practical or advisable for her to visit the family again. All white families in poor financial circumstances and all colored families are given as much attention as the unit officers think necessary, but all are seen at least twice before the babies are 6 months old. After the first visit, if the mother becomes a regular attendant at the health center the home is not visited unless there is some particular reason for so doing.

Formerly it was the custom of the nurse to devote Saturday mornings and about an hour at the end of each day to clerical work. Under the present plan the nurse is allowed only a short time each day in the office to receive instruction unless a conference is to be held. The clerk has complete charge of the files and they are all kept in uniform order so that a representative from the State Board can obtain a reasonably accurate idea of conditions in any and all districts in a minimum of time.

The nurses are now more keenly interested in preventing as many infant deaths as possible and in finding unreported births, so that the infant mortality rate may be as low as possible in their districts. They are not devoting as much time to work not pertaining to their own field of activities as formerly.

More effective work of the infant hygiene nurses and better records alone will not solve all of our problems in this field, but at least it seems to be a step in the right direction.

Under the present plan of operation we have a better idea of the conditions prevailing and a better basis upon which to construct the infant hygiene program.

Sweden—Prenatal and Infant Health Work

THE first report on the prenatal and infant health work started by the National Government of Sweden on October 1, 1931, mentions the success of the work and quotes requests from many localities for its continuation. A special committee of experts recommended in 1929 the organization throughout the country of a system of prenatal and infant health work. As a result it was decided to begin the work by way of experiment in four Provinces; the national legislature appropriated the money, and the beginning was made on October 1, 1931. Some time in advance a preparatory campaign was instituted by the Government for the purpose of familiarizing the public with the importance of preventive health work. Notices were printed in the press, literature was distributed, and talks were given by the public health nurses, midwives and others.

The work was of a preventive nature and was concerned with expectant mothers and young mothers and their infants. It was performed by the health officers of the Provinces, who were physicians, with the assistance of the district nurses and district midwives, and was under the supervision of two experts who made inspection tours through the different places. Most of the work was done in rural communities, although a few cities were also included in the territory. Expectant

mothers were given thorough physical examinations and instruction in the proper care of their health by the health officers. Home visits were made by the district midwives. The post-natal care was carried out by the health officers assisted by nurses who also visited the mothers and children at their homes. A certain amount of follow-up work was also done.

The reports for each of the four Provinces where the work was done show that 40 per cent of the expectant mothers and 50 per cent of the newborn infants received preventive care; this, although admittedly not a high percentage, is considered a good showing for a new undertaking, particularly in view of the cold weather, long distances, and bad roads. In general, the public showed great interest in the work and were particularly appreciative of the preventive care, although in some cases the value of the work was underestimated. Some immediate results of the work have already been observed; for instance, greater attention on the part of the mothers to the cleanliness of the infants and of their beds and clothing. On the whole, the experiment is considered sufficiently satisfactory to warrant good expectations for the future.

The National Government has extended its appropriation to July 1, 1933.—*Tidskrift för Barnavård och Ungdomsskydd*, Stockholm, 7, 5, 1932.

Nonspecific Flocculation of Diphtheria Antitoxin, Toxin, and Toxoid, and Its Bearing on the Lf Titer

JOHN F. ANDERSON, M.D., F.A.P.H.A., GEORGE F. LEONARD, M.D., AND AUGUST HOLM, Sc.D.

Biological Laboratories, E. R. Squibb & Sons, New Brunswick, N. J.

THE titration method by flocculation of diphtheria antigen and antitoxin, has been suggested as an evaluation of the antigenic and antitoxic properties.

The flocculation test has been termed "rigoureusement spécifique" by Ramon,¹ and the idea has gradually developed that animal tests are unnecessary for the determination of antigenicity and antitoxin unit content, and that the much easier flocculation method can be substituted without loss of accuracy.

DEVELOPMENT OF THE FLOCCULATION TEST

Early work by Calmette and Massol² showed that toxin and antitoxin would flocculate in a test tube when mixed, and a method was developed for the measurement of the antitoxic value of anti-venom by flocculating it in increasing amounts with a constant volume of cobra venom.

Nicolle, Césari and Debains³ described the flocculation of diphtheria toxin and of tetanus toxin by their homologous antitoxins, but their method of titration involved concentration of the toxin by sodium sulphate, admixture of the concentrated toxin with gelatin, and a ring test with varying dilutions of antitoxin.

Ramon⁴ developed a simple method

by which he determined the number of antitoxic units of diphtheria immune sera, and the antigenic value of diphtheria toxins and toxoids. Serum and antigen were mixed in different proportions in test tubes, and the tube which flocculated first was selected as containing a neutral mixture of antigen and serum—Ramon's "flocculation initiale."

Ramon's work was soon confirmed by Schmidt,⁵ Scholz,⁶ Glenny and Okell,⁷ Bayne-Jones,⁸ and many other investigators, and the flocculation (Lf) value was defined as the amount of toxin, equivalent to one unit of antitoxin as determined by flocculation. The Lf value of a toxin or a toxoid is frequently referred to as "antigenic value" or "immunizing value."

RELATION OF FLOCCULATION TO PRECIPITIN TEST

Soon after Ramon's publication, several workers, however, raised the question whether the flocculation reaction really was different from the well known precipitin reaction, which generally takes place between an antigen and its homologous antibody.

Bronfenbrenner and Reichert⁹ studied botulinus toxin and came to the conclusion that the amount of flocculation and the width of the flocculating zone varied approximately with the esti-

mated amount of bacterial protein in the toxic filtrate, and that the flocculation of toxin with antitoxin was a specific bacterial precipitation phenomenon.

Moloney and Weld¹⁰ found that there was "no obvious relation between the agglutination titer of a serum and its antitoxic content."

Schmidt¹¹ also observed that the precipitate which forms when antibacterial precipitin is added to diphtheria toxin does not remove the toxin nor interfere with its subsequent flocculation with antitoxin. A new flocculation occurs when the toxin, from which precipitable bacterial residues have been removed, is added in equivalent proportions to the antitoxin. After removal of the precipitate formed by antitoxin in the "indicating tube" showing the "flocculation initiale," no further flocculation occurs when more antitoxin is added. Bayne-Jones¹² has confirmed these experiments and demonstrated the independence of the toxin-antitoxin flocculation with reference to bacterial proteins.

DISCREPANCIES IN THE FLOCCULATION TEST

Glenny,¹³ and Glenny and Wallace¹⁴ state that the flocculation reaction sometimes would give widely diverging values when compared with animal tests. For example, the flocculation value of a serum was 160 units, while animal tests showed that the serum contained 260 units.

The authors of the present paper have repeatedly made similar observations on titrations of trial bleedings. For instance, the flocculation value for one horse was 550 units, while the guinea pig tests showed more than 1,100 units.

Another source of discrepancies is the zone phenomenon, where flocculation occurs in two or more zones with the same amount of toxin, but with

different amounts of antitoxin. This phenomenon is especially prevalent in the flocculation of mixtures of tetanus toxin and antitoxin,¹⁵ on account of which the tetanus flocculation has not been accepted as a measure of antigenic and antitoxic units; but the zone effect is occasionally met also in the flocculation of diphtheria antigen and antitoxin.¹⁶

Povitsky¹⁷ relies almost entirely upon the Ramon flocculation test for the titration of toxoid, and she states that since 1924 this test has been used in all phases of toxin, toxoid, and antitoxin production for the determination of antigenic and antitoxic units. She is of the opinion that the discrepancies between guinea pig and Ramon test noticed usually are due to the wrong proportions of toxin and antitoxin, and explains it as follows:

When a serum gives a reaction at the usual temperature with the standard toxin in 2, 3, or more hours, when it should give it in 1 hour, we know that the amounts of toxin and antitoxin are not proportionate. The test is repeated several times until the reaction is obtained within the proper time. The Ramon test, when the amounts of toxin and antitoxin are proportionate is, in the opinion of the author, one of the most reliable we have. The reactions which occur later on either side of the indicating tube are not specific and may lead to wrong calculations.

In this connection it may be stated that some horses may give antitoxic sera that flocculate in 2 hours,¹⁸ 3 hours, and 6½ hours,¹⁹ and that flocculation time is greatly influenced by the temperature of the water bath in which the flocculating tubes are immersed.

Linderström-Lang and Schmidt²⁰ prepared a purified antitoxin by alcohol precipitation and ether extraction which did not flocculate, but had retained its avidity and neutralizing power for toxin.

Jensen²¹ calls attention to investiga-

tions carried on at the State Serum Institute at Copenhagen, according to which the correctness of Ramon's contention, that the flocculation value is an expression of the immunizing power, must be considered questionable.

Bächer and Kraus²² caution against the identification of flocculation with toxin-antitoxin binding, and have prepared antigenic diphtheria toxins which did not flocculate.

In the concentration and purification of diphtheria toxin and toxoid, this lack of power to flocculate is often encountered, although the antigenicity is retained or only somewhat diminished.^{16, 23} This is, for instance, the case in the purification by alcohol, by acids, and by combined acid and alcohol precipitation.²⁴

On the other hand, Gross,²⁵ and later Ecker and Weed,²⁶ purified diphtheria toxin by adsorption to magnesium hydroxide and colloidal magnesium, but although their purified product contained about 32 "antigenic" (flocculation) units per c.c., which value was determined by Povitsky, the purified toxin was completely lacking in antigenicity, being incapable of immunizing rabbits and guinea pigs.

Not only absence of ability to flocculate, with retained immunizing power, and high flocculation values with lacking antigenicity are found, but non-specifically increased flocculation values are also encountered.

When toxins and toxoids, which have been purified by adsorption to aluminum hydroxide,²⁴ are eluted by a solution of disodium phosphate and the elution is made up to the original volume, the flocculation value will in some instances be increased to much more than 100 per cent, while the flocculation time is considerably decreased. Figures on record show that a toxoid which originally flocculated 12.4 units per c.c. in 2 hours and 6

minutes increased its flocculation value to 17 units in 25 minutes, although it was evident from animal experiments that the recovery of the toxoid from the precipitate by elution was far from complete.

It has always been the object to produce as strong a toxin as possible for the production of antitoxin, and the increasing use of toxoid of high antigenic value for immunization against diphtheria has stressed the demand for strong toxin. A toxin containing 10 to 15 flocculation units was until lately considered a strong toxin, but it is now possible to make toxins of 60 flocculation units²⁷ or even more,²⁸ and concentrated toxins and toxoids of several hundred units.

The chemical composition of the floccules which are formed when diphtheria toxin and antitoxin are mixed in suitable proportions has been investigated by Flössner and Kutscher²⁹ who found that the floccules consist of 86.36 per cent magnesium ammonium phosphate, 10 per cent alcohol-insoluble protein, 1.1 per cent alcohol-soluble protein, and 2.52 per cent lipid.

The organic constituents of the floccules have been attributed to bacillary lipoprotein and serum precipitins, and Moloney and Weld¹⁰ suggested that the toxin-antitoxin complex merely was carried down by adsorption. Hartley³¹ proposed that the toxin-antitoxin compound was adsorbed upon lipoids which became flocculated from the serum during the reaction, and Friedberger and Ikeda³² were of the opinion that the toxin-antitoxin complex was largely a lipoidal aggregate.

It may be mentioned in this connection that Lohmann³⁰ has demonstrated the presence of pyrophosphates in striated muscle, in yeasts, and in bacteria. Pyrophosphates will react with magnesium compounds and form precipitates which are soluble in an excess of pyrophosphate solution, as well as in

TABLE I
FLOCCULATION DETERMINATIONS

| 2 c.c. of | Amount of Antitoxin etc. in 0.001 c.c. | | | | | | Time | Antitoxin etc. | Indicated Units |
|--|---|-------|-------|-------|-----|-----|-------------|-------------------|--------------------|
| Saline with 0.1% Sod. Pyroph. | 2,000 | 1,500 | 1,000 | 750 | 500 | 250 | 2 m. | 1,389 | >400 |
| Saline with 0.025% Sod. Pyroph. | 2,000 | 1,500 | 1,000 | 750 | 500 | 250 | 3 m. | 1,389 | 300 |
| Saline with 0.0175% Sod. Pyroph. | 1,200 | 1,100 | 1,000 | 900 | 800 | 700 | 12 m. | 1,389 | 180 |
| Saline with 0.01% Sod. Pyroph. | 2,000 | 1,500 | 1,000 | 750 | 500 | 250 | 25 m. | 1,389 | 150 |

(b) Copious flocculation.

an excess of the solution of the magnesium compound. By using pyrophosphate and magnesium in colloidal suspensions, or as compounds where they are chemical components of pro-

tein, and employing them according to the Ramon flocculation method, flocculations take place especially in the presence of ammonia salts which are indistinguishable from flocculations of

toxin and antitoxin. There is the same "flocculation initiale" as demonstrated by Ramon, with an "indicating tube," and a supernatant liquid which after removal of the precipitate is free for flocculation producing compounds.

EXPERIMENTAL

Non-specific Flocculation—The general application of the flocculation test in the production of toxin and antitoxin, makes it necessary to know as much as possible about factors which may cause non-specific reactions and consequently erroneous calculations, so that these irregularities may be detected or guarded against.

Observations at this laboratory show: (1) that the flocculation value of a 2½ year old toxoid does not always correspond to the value established by animal tests, but may give a low flocculation value and yet be of satisfactory antigenic activity; (2) that the flocculation of a fresh toxin also occasionally may show irregularities with high flocculation value and lower toxicity than expected according to the flocculation test; (3) that precipitation of extracts of diphtheria bacilli readily takes place with homologous serum, often simulating a true flocculation; and (4) that toxin broth, which accidentally had become contaminated during the production of diphtheria toxin showed higher flocculation values than the uncontaminated flasks.

In view of these facts, and as elutions of toxoid precipitates by disodium phosphate gave too high flocculation values, as floccules largely consist of magnesium ammonium phosphate, as pyrophosphates are present in meat and bacteria, and as pyrophosphates will flocculate with magnesium compounds, a number of flocculations were carried out to determine the influence of the pyrophosphates on the flocculation values. Diphtheria toxins, toxoids, and antitoxins, and different proteins have been

mixed with sodium pyrophosphate, with magnesium sulphate and with colloidal magnesium, and flocculated according to Ramon's method.

Technic—The volume of toxin in each tube was 2 c.c. The test tubes were 10 cm. long and 0.73 cm. in diameter. The pipetting was done with 0.1 c.c. pipettes, which are graduated in 0.001 c.c., and the pipettes were wiped off with moist cotton after each immersion into the antitoxin. The water bath was kept at 50° C., and the amount of water in the bath adjusted to cover half of the column of fluid in the tubes.

Some typical flocculations are recorded in Table I and the following reagents were used:

Saline was a 0.85 per cent solution of sodium chloride.

The peptone is "Proteose Peptone" from Digestive Ferments Co., Detroit, and was dissolved in saline.

The bacterial protein solutions were neutral, acid and alkaline saline extracts.

The toxoid 14,957 was made from infusion free medium.⁵³

All antitoxins used contained 400 units.

DISCUSSION

It is apparent that pyrophosphates may simulate a true flocculation, and that the addition of pyrophosphates to diphtheria toxin and toxoid can modify the flocculation values.

Since analysis of the floccules in the ordinary flocculation of antitoxin by toxin shows that the floccules mainly consist of magnesium ammonium phosphate, it does not seem improbable that the true flocculation of mixtures of toxin or toxoid and antitoxin is in some way connected with phosphate-magnesium precipitation in the presence of ammonia. Phosphates are present in all media used for the production of toxin, magnesium is a constituent of antitoxin, and ammonia is a metabolic product of the diphtheria bacilli.

It seems therefore as if the flocculation reaction might consist of three different but interlocking reactions: first, a phosphate-ammonium-magnesium reaction; secondly, a bacillary lipoprotein-nucleoprotein-precipitin reaction; and, thirdly, a neutralization of toxin or toxoid by antitoxin. Flocculation, therefore, may be a simple neutralization of toxin or toxoid and antitoxin, or it may be a combination of neutralization and a non-specific reaction, or a non-specific reaction alone.

Since the avidity of a toxin or a toxoid may be changed and considerably lowered by purification, which also removes most of the inorganic constituents, or may be increased as shown by decreased flocculation time, for example, in the case of phosphate elution of toxoid precipitated by aluminum hydroxide, the avidity phenomenon may be more complex than is usually considered. It may, to a certain degree, depend also upon inorganic compounds, which possibly are present as integral parts of the toxin and the antitoxin.

SUMMARY

1. The Ramon flocculation test of diphtheria toxin or toxoid and antitoxin has been claimed to be rigorously specific. Certain non-specific flocculations are, however, encountered, as for example by bacillary proteins, by phosphates and pyrophosphates.

2. Phosphates and pyrophosphates may under certain circumstances enhance the flocculation reaction of diphtheria toxin and antitoxin. This enhancement is expressed by increased flocculation value and decreased flocculation time.

3. The flocculation reaction consists possibly of interlocking reactions of inorganic constituents of the toxin and serum, of bacillary lipoproteins or nucleoproteins and serum precipitins, and of toxin and antitoxin.

Flocculation may be a simple neutralization of toxin or toxoid and antitoxin, or it may be a combination of neutralization and a non-

specific reaction, or a non-specific reaction alone.

4. The flocculation reaction is not always specific and, therefore, is not always a true measure of the antigenic value.

5. The flocculation time is not always a true measure of avidity, as determined by flocculation.

Prevention of Lead Poisoning in Industry*

G. H. GEHRMANN, M.D., F.A.C.P.

Medical Director, E. I. du Pont de Nemours & Co., Wilmington, Del.

THE discussion of this subject, which is probably one of the oldest, if not the oldest, of known industrial hazards, hardly calls for an introduction dealing with its history. No one will dispute the fact that prevention is the only remedy that can be considered as practical.

I propose to present the methods of prevention which have been in actual operation in our company since 1926, as devised by our own Medical Department with the assistance of Dr. Robert A. Kehoe, of Cincinnati, Ohio, in the manufacture of tetra ethyl lead. I have chosen this particular operation because it represents the manufacture and handling of one of the most dangerous lead compounds in industry, being highly toxic by all 3 avenues of entrance, viz., the gastrointestinal tract, the respiratory tract, and the skin. This is the only known lead compound to enter the circulation by the latter route in sufficient quantities to cause poisoning. Since the adoption of preventive measures as formulated in 1926 this operation has been conducted up to the present time without a single case of lead poisoning, and in only a very few instances sufficient absorption to warrant the removal of a man from work. I do not mention these facts in an attempt to glorify our records, but simply to call to your attention that, no matter how toxic the substance,

it can be produced and handled safely under the proper precautionary measures.

Preventive measures are divided into two major classes—those applicable to the workmen, and those of operation. All methods of both classes must be carefully planned, rigidly enforced and maintained with the utmost care.

The methods and rules applicable to the workmen are the most detailed and the most difficult to maintain. They begin with a physical examination before the workman is allowed to enter the plant. The examination must be made with great care, and sufficient time allowed to cover intimate and essential details. I do not propose to enter into a detailed description as to how a physical examination should be made; but I wish to point out a few details that require careful analysis.

The first essential is a complete history of the applicant's previous industrial life, covering his entire working period from the beginning and up to the time of his examination. This history must be very carefully taken and any previous exposure to lead is a definite contraindication to acceptance unless the examiner can assure himself that the exposure was insufficient to have caused appreciable absorption or the industry in which he was employed gave sufficient protection to prevent absorption. Both of these questions are difficult to answer satisfactorily, and I simply mention them as possible qualifications to acceptance. It is unsafe, and decidedly dangerous to the appli-

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

cant, and a potential hazard to the employer, to accept an applicant who is already leaded to any degree.

There are certain characteristics which if recognized should be sufficient to exclude the applicant. For example, the lead worker must be amenable to the teachings of cleanliness and sanitation, and the individual whose appearance indicates chronic slovenliness is always a difficult problem and may, in spite of your best efforts, succeed in getting himself into serious difficulties. The irresponsible and, to use the common expression, the "wise guy," will invariably fail to follow instructions and often take keen delight in disobeying them. It is often impossible to impart understanding to one who has insufficient powers of absorption and retention. I refer to those whom we classify as decidedly below normal intelligence. These facts are decidedly pertinent to successful continuance of the operation, because the rules and regulations are numerous and are the very foundation of successful prevention of lead absorption, and each employee must carry out his own particular rôle with exact precision at all times.

Females, and all applicants under 21, are recognized as decidedly prone to lead poisoning, and should be excluded. Also, I feel that applicants over 45 should be eliminated.

After ascertaining these facts, and before making the actual physical examination, the applicant should have carefully explained to him (1) the danger of the operation for which he is being considered; (2) that he will have to work under definite rules which are for the protection of his health, and failure to obey them will mean the possibility of his own illness or dismissal; (3) that the Medical Department is operating for his protection and he is free at any time to present to it complaints of any nature relative to his own personal health, and always on the

company's time. This last point is extremely important, as I have found it very difficult and almost impossible to get workmen to sacrifice even a few minutes of their own time.

Immediately following this explanation of danger, the applicant should be asked whether or not he is desirous of working under such conditions, and he is dismissed from further consideration if his answer is negative or if he expresses fear. Employees who are afraid of lead work are very liable to be constantly presenting subjective symptoms with no objective findings, and soon become a problem to the examiner.

The personal history should bring out certain facts, such as the presence of chronic gastrointestinal disorders, gastric or duodenal ulcer, bowel habits and appetite, with special reference to breakfast. The average workman eats a good breakfast, and one of the early subjective symptoms of lead poisoning is a lack of early morning appetite. Sleep and its nature should be recorded, as insomnia and dreams are early symptoms of lead poisoning. The particular point that I am trying to make is this—if you record a complete history at the time of employment, it is easy to check any alleged changes later, but without the initial record you will find it extremely difficult to arrive accurately at definite conclusions.

The actual physical examination is conducted in the usual complete manner, and bearing in mind the general toxic effects of lead there are many conditions that necessitate rejection of the applicant, such as circulatory disturbances of any nature, nephroses, acute or chronic infections, syphilis, diabetes mellitus, neurological disturbances of any kind, anemias, and carious teeth until repaired. It is our policy to have the teeth of our men, after acceptance, examined, cleaned and repaired by our own dentist, who

operates at our plant on a full-time basis.

A complete blood count must be made at this time with a careful search for stipple cells, for future comparison. We have often found applicants showing numerous stipples who have denied previous lead exposure, usually intentionally. The presence of stipple cells is sufficient cause for rejection.

The applicant who has passed this physical examination must be in good physical condition, and from this point on it is the moral and legal obligation of the employer to exert every possible human effort to maintain and protect his health by (1) careful and frequent medical examinations, (2) rigid rules of conduct during working hours, and (3) installation and maintenance of proper mechanical protective and operative devices.

MEDICAL EXAMINATIONS

The frequency of medical examinations is, in all industrial hazards, determined by the toxicity of the material being handled, the possibility and rate of absorption, and the minimum time in which physical signs and symptoms may appear. We made our lead examinations weekly for several years, and by virtue of our experience have now changed the schedule to every 3 weeks.

Each examination consists of a careful search for subjective and objective signs of lead absorption, including a complete blood count, with a careful search for stipple cells. In our stipple cell counts we examine 50 oil immersion fields, and consider the presence of these cells as indicative of lead absorption, but regardless of the number, in no way indicative of the degree of absorption. The degree or severity of lead absorption must be decided by the presence of subjective or objective symptoms and signs, either one or both, together with blood changes as deter-

mined by a reduction in the hemoglobin, a reduction in the number of red cells and the presence of any number of stipple cells.

The periodic lead examinations must be conducted on a regular schedule and in the event of any doubt or suspicion as to the presence of even very slight signs or symptoms, the patient should be immediately subjected to daily observations until his condition is definitely determined. It is most difficult to set up any definite standard for determining when a man has absorbed sufficient lead to warrant his removal from the work, in order to prevent the appearance of symptoms. In general, I believe it safe to say that when a worker begins to show even a slight digestive change, has lost a little weight, lacks a noticeable degree of his original stamina and shows stipple cells with some reduction in the number of the red cells and hemoglobin, he should be removed. To some this might seem like the actual presence of lead poisoning rather than lead absorption, but regardless of the degree, this type of worker can be changed to a lead-free occupation without any loss of time and in a relatively short period be entirely symptom free. In other words, he has not been poisoned to the point of invalidism, has not suffered any lasting effects and can be eventually returned to his original work. The occurrence of absorption in sufficient degree to warrant removal indicates faulty operative methods or failure to follow working rules, and calls for immediate investigation to determine the real source of the trouble and the application of proper remedies.

I should say something about the estimation of lead in the urine and feces. We do not make these estimations as a routine because we are convinced that our examining technic is sufficiently thorough to detect any appreciable degree of lead absorption, and

there are too many details and too much time is involved in making these tests properly to warrant the expense. The amount of lead in the feces is not a true indication of the amount absorbed as it is impossible to determine how much has passed directly through the intestinal tract and how much has been excreted. Lead in the urine must necessarily represent lead that has been absorbed, but before a worker is excreting sufficient quantities to denote lead poisoning he should have been eliminated by the physical examination.

RULES OF CONDUCT

Before stating any rules that govern the daily conduct of lead workmen, I wish to call your attention to the fact that before these can be properly enforced, each worker must be carefully instructed in each individual rule, and must be supplied with certain necessities that will enable him to follow out every detail. He cannot take a bath unless provided with the proper means, neither can he put away his street clothing if there is no place to put it, and unless provided with a lunch room he is apt to eat in any convenient place. I have seen factories where the rules of conduct were quite adequate, but the management had made no provision for the equipment necessary, thus making them a mere gesture toward precaution.

The first necessity is a proper change house, and I strongly recommend that the house have two locker rooms, one for the street clothing and the other for the working clothes, and adjoining or between them washing and bathing facilities. Shower baths should be attractive and sanitary in construction, and above all should be kept clean and orderly. A lunch room in the change house is the ideal location as it gives each worker the opportunity of storing his lunch in his own locker and provides the necessary washing facilities which he must use before eating.

Rules which each lead worker in our employment must follow are:

1. Before going to work each man is given two clothing lockers located in different rooms, one to be used for street and the other for working clothing.

2. Each day before reporting for work he must remove all street clothing and put on a complete working outfit. We supply these outfits, 2 to each man, and they are washed in our laundry twice a week, at company expense.

3. At the end of each day every man must take a shower bath.

4. No food of any kind may be taken into or consumed in the lead buildings. All lunches must be eaten in rooms provided for this purpose and each man must wash his face and hands before eating.

5. Each worker must carefully obey all the rules of operation and immediately report the faulty operation of any equipment.

6. Every worker must report to the Medical Department when sent for and at any time when he does not feel well.

7. Anyone who is unable to report for duty for any reason whatsoever, unless previous arrangements have been made, must communicate with his foreman on the day of his absence and give his reason for failure to report. This rule keeps us in constant contact with every worker and when he reports sick his case is immediately investigated by our Medical Department.

The adoption of working rules and the institution of employment and periodic examinations may be safely considered as essential in all lead operations, but must always be supplemented by factory control methods of operation. I have frequently heard it said that sanitary rules are sufficient to control any lead operation, and I very definitely deny this assertion. The most rigid examinations and the most elaborate sanitary working rules will not prevent lead absorption and lead poisoning in a dirty operation, and by this I mean one where lead dust or fumes are constantly in the air.

A great deal has been written relative to the exposure necessary to produce lead symptoms and it is generally accepted that the absorption of from

1 to 2 milligrams per day will cause lead poisoning in from 9 months to 1 year, while the absorption of 10 milligrams per day will cause acute poisoning in a few weeks. However, when we take into consideration certain unknown factors such as personal susceptibility, rate of absorption and tolerance together with the amount of air contamination, as carefully measured by chemical analysis, it is impossible to state definite figures in milligrams per cubic meter which may be considered safe for any group of workmen. This being the case, the only safe method of operation is the one in which the lead content of the air is reduced to the absolute minimum. I question the possibility of absolute freedom of lead dust and fume in certain types of operations, at least with the present available equipment.

There has been much discussion as to the comparative toxicity of various lead compounds and here we are dealing, not with the toxicity of the actual material, but with the amount that is being absorbed, and the safest method is to consider them all toxic and institute measures that will give minimum absorption.

The two major industrial problems are elimination of dust and fumes. Dust problems have two main points of origin—the method of handling materials, and process machinery. The handling of dry, dusty lead compounds can be controlled to a certain degree by instituting a careful method, but these measures tend to slow up the operation and are always dependent upon careful supervision at all times, as the human element of carelessness is certain to become troublesome. The use of respirators is fairly satisfactory provided the respirator is efficient, comfortable to wear, and is worn at all times. Anyone who has had experience with respirators must admit that under the most favorable circumstances they

leave much to be desired. This narrows the field down to the most efficient and satisfactory method of dust control at the point of origin, which is exhaust ventilation.

Exhaust ventilation, properly designed and properly maintained, will reduce dust hazards to the absolute minimum. The type of hoods, the rate of exhaust, and all other problems in connection with the operation can be readily solved by ventilating engineers. The consideration of these details is an engineering problem, not a medical one. Our own experience has proved that although the initial installation is somewhat expensive, the final results amply justify the cost. Exhaust ventilation not only controls the dust problem but also the fumes. In our lead ethyl operations we have surrounded practically every piece of equipment and, in addition, force fresh, clean air into all workrooms in sufficient quantity to make two complete changes each minute.

I realize that there are a great many companies handling various lead compounds at present whose operations are hazardous to the employees and who because of present business conditions cannot spend the necessary money to install either new equipment or exhaust ventilation. Such operations should be cleaned up in so far as possible by tightening up all equipment, instituting careful methods of handling materials, careful rules of sanitation for the workmen, and competent medical supervision.

Cleaning and keeping clean all factory workrooms is extremely important. Dry sweeping should never be allowed. Floors and equipment should be washed down whenever possible; and under circumstances which do not permit of the use of water, vacuum cleaning is the method of choice. A few dry sweepings can soon undo all the good accomplished by months of careful observation

and sanitary control. Rafters, beams, windowsills, and all dust collecting parts must be kept free from dust to prevent air contamination by draughts and jarring caused by the vibrations of the equipment.

Chemical analyses to determine the lead content of the air should be made very frequently at all parts of the work-rooms; must be conducted by a trained individual; and a record of each test supplied to the Medical Department, as they indicate those operations or sections of operations where trouble is most likely to occur. They also make it possible to pick out the workmen who are subjected to these conditions and watch them more carefully for lead absorption. Such tests act as a check upon the efficiency or lack of efficiency

of machinery and exhaust ventilating devices, and indicate the necessity for immediate improvement. I cannot lay too much stress upon the real value and the urgent necessity of air analyses in any lead operation, and I am convinced that the expense incurred is many times compensated for by the actual benefits which result by following up and stopping the leaks that are detected.

In conclusion, I would say: Pick your workmen carefully by complete examinations; instruct them thoroughly in the rules that must be followed all during their working hours; and eliminate dust and fumes at the source. If you do all these things properly, lead absorption will be reduced to a minimum and you should eliminate all cases of lead poisoning.

Antituberculosis Work Among Children in Italy

IN a recent circular to the local anti-tuberculosis committees, which in compliance with the law on compulsory insurance against tuberculosis have been organized throughout Italy, the Minister of the Interior urges the application of preventive measures, particularly to children who have tuberculous parents or who live with tuberculous persons.

Preventive action must begin as early as the prenatal period. It is necessary to search for expectant mothers affected with tuberculosis and to provide for them the necessary treatment, whether in a hospital or, if advisable, in their homes. The infant living with a tuberculous mother or in the same home with another tuberculous patient must be supervised either by the family

physician or by a physician from the public tuberculosis clinic. Visiting nurses must teach these mothers proper care of their infants. In a case in which it is not advisable to leave the infant in his own home, he should be placed in an appropriate public institution; the local branch of the National Children's Bureau should then be asked to coöperate with the local official anti-tuberculosis committee.

The Minister also calls the attention of the authorities to the importance of providing physical examinations for all school children and treatment for all active cases of tuberculosis among them and of establishing open-air schools for undernourished children and those suspected of tuberculosis.—*Le Assicurazioni Sociali*, Rome, 8, 5, 1932.

Agglutination in the Diagnosis of Enteric Disease*

RUTH GILBERT, M.D., F.A.P.H.A. (*Life Member*),
AND MARION B. COLEMAN

*Division of Laboratories and Research, New York State
Department of Health, Albany, N. Y.*

POLICIES adopted in 1913, when the New York State Department of Health was reorganized and Dr. Hermann M. Biggs was appointed Commissioner of Health, have resulted in the development of a highly efficient laboratory service throughout the state. A unique opportunity has thus been provided for the evaluation and establishment of standards, through the coöperation of directors of laboratories approved by the State Commissioner of Health with the staff of the central laboratory in Albany.

One of the most difficult procedures to standardize has been the agglutination test for evidence of typhoid fever. Microscopic tests with living organisms made in 2 laboratories where the same technic is employed and the same strain of *B. typhosus* is used may furnish different results with portions of the same blood specimen, even though the cultures are maintained under the most carefully controlled conditions. Moreover, the value of this type of test as an aid in diagnosis is limited, since similar reactions may be obtained with the

blood of persons who have typhoid fever, who have received typhoid vaccine, or who have a febrile disease other than typhoid fever.

The substitution of a carefully

Read before the Laboratory Section of the American Public Health Association, at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

standardized suspension of killed bacteria would lead to greater uniformity and could be recommended if reliable results could be obtained with it. Cultures killed with formalin have been extensively studied and their use has been advocated by a number of investigators. The findings obtained in our laboratory indicated that such suspensions were not satisfactory for the microscopic test.¹ Also, in macroscopic tests, occasionally sera from patients with typhoid fever failed to agglutinate suspensions killed with formalin when reactions were secured in tests with a living culture.

The importance of 2 types of agglutination which can be demonstrated with many species of bacteria was not fully appreciated for a number of years after Theobald Smith and his collaborators² had demonstrated, in 1903, that a nonmotile strain of the hog-cholera bacillus agglutinated in the form of a "granular precipitate," while motile strains of the same species agglutinated as a "fluffy precipitate." In 1917, Weil

and Felix³ investigated these properties of *B. proteus* and later they,^{4,5} as well as a number of other workers, made similar studies of species belonging to the enteric disease group. It was learned that data of greater diagnostic value could be secured by a method differentiating the granular from the floccular type of agglutination than by the microscopic test with living culture.

In view of these reports, during the last 3 years the microscopic test with living culture has been supplemented in our laboratory by a macroscopic test with an alcohol treated suspension, which agglutinates in a granular form, as well as one with bacteria killed with formalin, which agglutinates in a floccular manner.⁶ Last year, the New York State Association of Public Health Laboratories, an organization which has been most influential in the maintenance of high standards of laboratory service in the state, undertook a joint investigation of this problem. Sera from cases of enteric disease, from patients with various other types of febrile disease, and from typhoid carriers are included

| 1:80 | 2 | 5 | 1 |
| 1:40 | 6 | 0 | 2 |
| 1:20 | 0 | 3 | 1 |
| No agglutination | 1 | 1 | 2 |

in the study. Series of specimens from each patient are tested if they can be secured. The technic, in so far as possible, is the same in all of the cooperating laboratories. The central laboratory in Albany is furnishing the suspensions of *B. typhosus* treated with alcohol and with formalin so that identical antigens will be used. Our experience has indicated that both types of antigen remain satisfactory for at least 6 months.

The results obtained with specimens received in the Division of Laboratories and Research at Albany from January 1, 1931, to September 1, 1932, have been tabulated (see Tables I-VI). On the whole, they correspond with those reported by Felix and his coworkers. The findings indicate that agglutination in a 1:80 or higher dilution with a formalin treated antigen suggests one of 3 alternatives: that the patient has typhoid fever, has had such an infection in the past, or has received typhoid vaccine, while a similar reaction with an alcohol treated suspension usually in-

dicates that the patient has typhoid fever or an infection incited by a species of bacteria antigenically related to *B. typhosus*. Occasionally, as has been noted by Gardner and others,⁷ granular as well as floccular agglutination is obtained with sera from some persons who have received typhoid vaccine. Our findings suggest that at times the granular form of reaction may be the stronger of the two. However, a much smaller percentage of unexplained reactions is obtained with this procedure than with the microscopic test with living culture. Also, both granular and floccular types of agglutination have very rarely been observed in high dilutions of sera other than those from typhoid fever patients.

If the results of the joint investigation in which the Laboratory Association is participating confirm our findings, a means will be available for standardizing the agglutination test for evidence of typhoid fever, by the use

Italian Traveling Maternal and Child Health Centers

TRAVELING maternal and child health centers are now being organized in those places of Italy where no permanent centers are in existence. According to a recent circular of the Chief of the National Bureau of Maternal and Child Welfare of Italy these centers are to have as their main function the teaching to the mother of the proper care of herself and her child; treatment of illness will not be provided. The circular emphasizes the importance of inducing the mothers to attend the centers. The centers are

under the general supervision of the National Bureau of Maternal and Child Welfare and must coöperate with the local branches of the bureau. Accurate reports must be presented daily, weekly, and monthly to the provincial branch of the bureau. The centers must also report to the local branches of the bureau all cases of mothers who are in need of aid.—

Bollettino degli Atti Ufficiali dell'Opera Nazionale per la Protezione della Maternità e dell'Infanzia, Rome, Jan.-Feb., 1933.

Relationship Between Health Officer and Nurse*

Points of View of a Health Officer

JACOB C. GEIGER, M.D.

Director of Public Health, San Francisco, Calif.

THE aims of the public health nurse must be identical with those of the health officer if effective work is to be done. Harvey Cushing has said, "There is only one thing that can effectively bind people, and that is a common devotion."

Very simply stated, the common devotion or basic aim of all health workers is the prevention of disease. To accomplish this object is the task of the health officer. He must assemble the necessary machinery consisting of workers, materials, knowledge, skills, and laws. To make the machinery work is administration.

In the administration of a health department the health officer's first responsibility is to define policies and formulate programs. In this he is greatly helped by his bureau chiefs on whom he relies for technical expert advice. Because they serve both in the capacity of advisers and of executives, on whom rests the responsibility of getting the job done, these first lieutenants of the health officer assume great importance in the administration of a health department. Their ideals as professional public health workers must be of the highest, their loyalty unquestioned; particularly they must

possess the ability to execute wholeheartedly policies and orders which, though they may have been instrumental in forming them, they have not themselves set. In addition they must possess training and knowledge in their own special fields and must keep in step with progress. Here, in the caliber of his chief executives, the administrator finds his strongest tool.

Important among these lieutenants of the health officer is his chief public health nurse. Where questions of public health nursing are involved the health officer naturally turns to her for aid and advice. To her he gives the responsibility of translating the policy of the department into public health nursing routines and methods which will lead to practical accomplishment. She works out the details of *how* the thing is to be done and brings back to him the report concerning *what* has been done. In matters of staff administration such as assignments, working conditions, staff education and discipline, the widest authority is usually delegated to her by the health officer. She in turn keeps him informed of developments and accomplishments and often seeks his counsel and approval. The relationship between health officer and chief nurse must be founded on mutual trust and respect and, as has been stated before, their aims in public health work must be identical.

* Read at a Joint Session of the Health Officers and Public Health Nursing Sections of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27 '1932.

To arrive at complete understanding it is necessary that there be a feeling of free communication between the administrator and his executives. The health officer, busy and hard pressed for time though he be, holds himself accessible to his chief nurse practically at all times, and she should feel that any troublesome question or any doubt about policy or even a particularly vexatious case may be brought to him for help in its solution.

The health officer likes to feel that not only the heads of staff, but all staff members, look to him for counsel in certain individual matters. Though the staff nurse is expected to take up all matters of policy and discussion of individual cases with her immediate superiors she should also always feel welcome to see the health officer when unusual and important questions concerning herself in relation to the department arise.

To attend an occasional staff nurses' meeting is a pleasant duty of the health officer. It gives him the opportunity of becoming acquainted with some of his field representatives at first hand, and serves to establish a spirit of friendliness. In large organizations particularly the personal contact of staff worker with health officer, which is only afforded by his attending staff meetings, is invaluable in maintaining a feeling of unity and solidarity within the department. Though his purpose in attending may have been to bring encouragement and perhaps the knowledge of new developments to the field nurses, he often is himself stimulated by the interested response shown by an alert and enthusiastic group of public health nurses who are eager to hear of new developments and new knowledge in the field of their endeavor, and on whose devotion to the common cause he knows he can depend.

Since public health nursing is not an isolated activity but is intimately in-

terrelated with practically every aspect of modern public health, the public health nurse is expected to understand, in addition to her nursing technics, something of the principles, procedures, and objectives of every phase of public health.

Often, indeed, it is the nursing personnel who must carry out the program of related divisions. A bureau of child hygiene or a bureau of tuberculosis control is inconceivable without the public health nurse; yet it is generally recognized that good administrative practice requires a separate nursing division in a public health organization from whose personnel assignments are made to other divisions. To keep things running smoothly a friendly and understanding spirit of coöperation and mutual esteem between the nursing staff and other department workers must prevail.

The health officer as an administrator is vitally interested in qualifications and professional standards for all health workers. It is becoming more and more generally recognized that the nurse in public health requires special training and study. There are in the United States about 16 universities or schools of recognized standing which offer courses to graduate nurses in public health nursing. We have emerged from the time when each organization had to train its own personnel, though it is still true that many of the most excellent nurses in the field today got their public health training in the school of experience. The time has pretty well arrived when no nurse should be accepted for public health assignment without practical academic training in a recognized school. To foster this movement toward better trained public health nurses is an obligation of every health administrator.

The relationship between health officer and public health nurse is one of interdependence. She is his arm which

reaches every individual in the community, even the most humble. But for her many of the most important functions of the public health movements would fail. On the other hand, the public health nurse has a right to look to him for leadership, for program, for support. There is a common devotion to human welfare.

SUMMARY

1. The aims of the public health nurse and the health officer must be identical for good work; on the health officer rests the responsibility of setting the aims and policies of the department.

2. In planning a public health nursing program he is aided by his nursing staff, which carries to accomplishment, as far as possible, the policies and plans of the health officer.

3. The detail of public health nursing methods and routines as well as most details of staff administration are responsibilities delegated to the chief nurse.

4. The health officer should be easily accessible to the chief nurse and, when occasion warrants, to other members of the nursing staff.

5. His attendance at an occasional staff meeting is stimulating both to him and to the nurses.

6. A close feeling of understanding and mutual helpfulness must exist between the nursing division and all other branches of the health department.

7. The administrator in public health recognizes his obligation to support and further the movement to elevate the professional standards of public health nurses.

8. The relationship between health officer and public health nurse is one of interdependence.

Textile Work and Normal Childbirth

TWO studies were made recently, each in a separate district of Bavaria, of the relation between textile work and normal childbirth. The studies were concerned with 3,300 women and about 7,400 pregnancies. Two-thirds of the women were selected among textile workers and one-third for the purposes of comparison from other industries. The women textile workers showed a greater frequency of abnormal births, particularly premature births; anemia, rickets, and pelvic disorders were also more frequent among them. These differences were attributed to the effects of occupation because the general circumstances of the women in the two groups of cases were very similar. Among the occupational fac-

tors in the textile industry that were considered harmful to the women, the report mentions the posture and certain movements during the work, such as bending, lifting of weights, overstretching; the general strain of the work, particularly harmful during the second half of pregnancy, and the continuation of employment almost up to the time of childbirth were other factors. It is considered that this last fact may very well produce premature birth. Therefore, the author of the report recommends that the work be discontinued not later than 4 weeks before the expected birth, and that a rest period of at least 6 weeks be given after confinement.—*Soziale Praxis*, Berlin, 52, 1932.

Frozen Vegetables*

ROBERT P. STRAKA AND LAWRENCE H. JAMES, F.A.P.H.A.

*Food Research Division, Bureau of Chemistry and Soils,
U. S. Department of Agriculture, Washington, D. C.†*

IN a previous report¹ the writers recorded results obtained with tin containers and cardboard boxes (Peters' Type) containing frozen peas, some of which were inoculated with *Clostridium botulinum* spores. In those studies 14 tin and 9 cardboard containers were shown to have botulinus toxin after defrosting and holding at room temperature (80-90° F.) for 3½ days. No toxic materials were obtained in containers which had been immediately defrosted or in those placed in an ice box (50-60° F.) and held for 3½ days. This report deals with a similar study of hand-shelled peas which had been frozen in 16-oz. commercial glass jars.

A detailed discussion of the preparation of the raw materials, the technic of inoculation and packing, the methods of handling, freezing, transportation and storage, the laboratory examination, and the technic for the final identification of the toxin are contained in the previous report.

Each test condition included at least 16 containers. More than 320 glass containers were prepared.

Buffer suspensions of a mixture of dried spores** of 4 strains of *Cl. botulinum*, 2 Type A and 2 Type B,

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

† Food Research Division Contribution No. 162.
1. Straka, R. P., and James, Lawrence H. A Health Aspect of Frozen Vegetables. *A.J.P.H.*, 22, 5:473-492 (May), 1932 (any reference to "previous report" refers to this publication).

** The dried spores were prepared by Elizabeth W. Sommer, William Hooper Foundation for Medical Research, San Francisco, Calif.

were used in the inoculations (for details, see p. 476-477, previous report).

Each series was prepared in triplicate. The first, not inoculated, served as controls; in the second, each filled container was inoculated with less than 100 botulinus spores; and in the third with approximately 100,000,000 spores.

Although the filled, inoculated and sealed jars of peas were frozen slowly in a refrigerated room at 10° F., not one was cracked or broken.

While holding the containers at room temperature under the various test conditions, it was often found advisable to make a small opening in the metal lid as pressure developed, similar to the procedure sometimes followed with the tin containers (see previous report). The temperature in the ice box used for defrosting and holding some of the jars ranged between 50° and 60° F.

Before discussing the results in detail it should be emphasized that toxin was obtained only in the defrosted samples of peas that had been held at room temperature, and that all of these were definitely spoiled. No toxin was obtained from containers defrosted and examined immediately or from containers defrosted and held in an ordinary ice box. In these respects the results obtained with the glass jars are identical with those obtained with the tin and cardboard containers.

Seventy-two glass containers of frozen peas were examined; 24 had received no inoculation, 24 the dilute inoculum, and 24 the concentrated.

TABLE I

BOTULINUS TOXIN AND CULTURES FOUND IN THAWED PEAS PREVIOUSLY FROZEN
IN GLASS CONTAINERS

| Jars Examined | | Jars Containing Toxin | | | Jars Containing Cultures | |
|------------------|--------------|-----------------------|----------|---------------|--------------------------|----------|
| Total Containers | Inoculation | Number | Per Cent | Type of Toxin | Number | Per Cent |
| 24 | None | 1 | 4.16 | Type B | 8 | 33.3 |
| 24 | Dilute | 3 | 12.5 | Type B | 11* | 45.8* |
| 24 | Concentrated | 5 | 20.8 | Type B | 24* | 100.0* |

* Presumptive. The cultures isolated from these containers have not been identified or typed, since such information would add little to the results obtained.

Each of these lots was subdivided so that samples were defrosted according to each of the 4 methods described.

During the holding and thawing period at room temperature, 9 containers which showed definite signs of spoilage, became toxic. These included 1 uninoculated control, 3 that had received a dilute inoculation, and 5 that had received a heavy inoculation. Seven other uninoculated containers yielded *Cl. botulinum* cultures. The results are summarized in Table I.

In the previous studies the results showed that the method of defrosting and holding in a thawed condition materially influences the development of the toxin. The results when the glass containers are considered from the standpoint of different methods of defrosting and storage are also interesting. The 72 containers referred to in

Table I are classified in Table II according to their treatment following defrosting. As in the tests with the tin and cardboard containers, toxin was obtained in some of the samples held at room temperature, whereas no toxin was present in those defrosted and examined immediately, or in those held in the ice box after defrosting.

The tests for total anaerobic bacteria and total anaerobic spores showed that in almost all containers the cells far outnumbered the spores. The length of the period of holding at warm temperatures after defrosting, of course, influenced these counts. Table III shows the results obtained on the uninoculated glass containers. Studies so far have not covered those blanched in brine.

Duplicate containers for each test condition have been examined. Each

| 31 H | water | 5.8 | 1,000,000 | 10 | ? | A |
| 43 G | Blanch hot water | 6.2 | 1,000,000 | 0 | | .. |
| 43 H | Vacuum packed | 6.0 | 10 | 1,000 | 1-100 | † |

* Demonstrated in anaerobic count tubes, not spore count.

† Culture isolated was Type A, while the toxin in the container was Type B.

container number has received a letter in accordance with the method of defrosting and storage, as follows:

1. Water bath—2 hrs. (109.4° F.), A and B
2. Ice box—3½ days (50-60° F.), C and D
3. Room temperature—3½ days (80-90° F.), E and F
4. Water bath—boiled—held room temperature (3 days), G and H

As indicated in the previous report, botulinus isolations from the uninoculated containers were made from the spore count series of beef tubes, where possible, otherwise from the anaerobic count series.

Of the 24 uninoculated containers examined, cultures of *Cl. botulinum* were obtained from 8. The relation between the type of cultures present and the methods of preparation and defrost-

ing of these are shown in Table IV. Cultures were isolated from 3 in which the peas had not been blanched and from 5 in which they had been blanched.

It is significant that 7 of the 8 cultures obtained were type A, while, as given in Table I, all of the 9 containers showing toxin had Type B.

Table V shows the relation of type and strength of toxin to inoculation and methods of preparation and defrosting. It is interesting that toxic samples were obtained in peas which had been blanched in hot water as well as in those that had only been washed in cold water. The majority of the toxic containers were samples that had been stored at room temperature without cooking.

TABLE IV

TYPES OF CL. BOTULINUM CULTURES OBTAINED FROM UNINOCULATED GLASS CONTAINERS
DEFROSTED BY VARIOUS METHODS

| Sample Number | Method of Preparation | Method of Defrosting | Botulinus Cultures Isolated | |
|------------------|------------------------|-----------------------------------|--------------------------------|----------------|
| | | | Type | Dilution Count |
| 28 A | Washed cold water | Water bath 110° F. | A | 10* |
| 28 B | Washed cold water | Water bath 110° F. | A | 10 |
| 28 D | Washed cold water | Ice box | B | 10* |
| 31 A | Blanched hot water | Water bath 110° F. | A | 10* |
| 31 H | Blanched hot water | Boiled brine, room temperature | A | 10 |
| 43 A | Blanched-vacuum packed | Water bath 110° F. | A | 10* |
| 43 F | Blanched-vacuum packed | Room temperature | A | 10* |
| 43 H | Blanched-vacuum packed | Boiled brine, room temperature | A† | 100 |

* These cultures obtained from a tube in the anaerobic count series, not from spore count series.

† This container also showed Type B toxin.

TABLE V

RELATION OF TYPE AND M.L.D. OF TOXINS FROM SPOILED PEAS IN GLASS CONTAINERS TO
INOCULATION AND METHODS OF PREPARATION AND DEFROSTING

| Inoculation | Sample Number | Method of Preparation | Method of Defrosting | Toxin | |
|--------------|------------------|--------------------------|-----------------------------------|-------|--------|
| | | | | Type | M.L.D. |
| None | 43 H | Blanched hot water | Cooked brine, room temperature | B | 2 |
| Dilute | 32 E | Blanched hot water | Room temperature | B | 10 |
| Dilute | 44 E | Blanched hot water | Room temperature | B | 10 |
| Dilute | 44 F | Blanched hot water | Room temperature | B | 1 |
| Concentrated | 30 E | Washed cold water | Room temperature | B | 20 |
| Concentrated | 30 F | Washed cold water | Cooked brine, room temperature | B | 2 |
| Concentrated | 33 H | Blanched hot water | Room temperature | B | 5 |
| Concentrated | 45 E | Blanched hot water | Room temperature | B | 3 |

SUMMARY

1. Seventy-two glass containers of frozen peas, 24 uninoculated, 24 lightly inoculated, and 24 heavily inoculated, were examined.

2. No toxin developed in peas which were examined immediately after defrosting, and none developed in those defrosted and held for 3 days in the ice box.

3. Toxin was obtained from the spoiled peas in 1 of the 24 uninoculated containers, and botulinus cultures were recovered from 8.

4. The spoiled contents of 3 of the 24 lightly inoculated containers were toxic and cultures were obtained (presumptive identification) from 11.

5. The 24 heavily inoculated containers showed 5 to be toxic after spoilage and the organism was recovered (presumptive iden-

tification) from every container.

6. All the toxic containers showed Type B toxin.

7. Of the organisms recovered from uninoculated containers, 7 were Type A and 1 was Type B.

ACKNOWLEDGMENTS—The authors are greatly indebted to Drs. F. C. Blanck, K. F. Meyer, and J. R. Esty for helpful suggestions and criticisms throughout this work. The assistance of the Glass Container Association and the Hazel-Atlas Glass Company in furnishing equipment, and the generous coöperation of the Seattle Laboratory, Food and Drug Administration, and the Port of Seattle, are gratefully acknowledged.

Mineral Analysis.—Qualitative examination showed the following elements absent, As, Cu, Al, Zn; a trace of iron Ca, Mg, K, Na, present. Also considerable PO_4 .

The most common comparison concerning which we have inquiries is as to milk. Sherman gives 314 calories to the pound of milk. It will be seen by the above that 6 beers average 191 calories to the pint; that is, not quite $\frac{2}{3}$ the value of the pint of milk so far as calories go.—Walter H. Eddy, M.D., Teachers College, Columbia University, New York, N. Y.

A TRIUMPH FOR PUBLIC HEALTH

THE City and County of San Francisco proudly chalks up another victory for the modern concept of public health. The question of a safe milk supply has been settled by the passage of a model milk ordinance.

In 1928 the Board of Health, at that time an executive body, passed a resolution setting January, 1933, as the time when all milk coming into the City and County of San Francisco should be from tuberculin tested herds. In November, 1932, an ordinance was presented to the Health Committee of the Board of Supervisors to make this resolution effective. In addition to requiring all milk to be from tuberculin tested cattle, the ordinance required all milk which was not certified to undergo pasteurization, and further that milk used for cream separation should comply with the specifications for Grade A market milk.

Since 1912 compulsory pasteurization has been in effect for 98 per cent of the milk supply, the few exceptions being certified and guaranteed raw. Certified milk is produced under the supervision of the Milk Commission of the San Francisco County Medical Society. Guaranteed raw milk is tuberculin tested and has a bacterial count of not over 10,000 per c.c. but is not certified. In the opinion of the Director of Public Health the inspection service given this guaranteed raw was insufficient. It did not measure up to the certified standard of inspection and the guarantee was in name only.

Dealers in certified milk had reduced the price from \$.25 to \$.17 per quart, but guaranteed dealers had not followed suit and were getting more than was originally charged for certified milk. One of their principal objections to submitting to certification was the increased cost of production.

The milk supply of San Francisco comes from 340 dairies and amounts to 50,000 gallons per day. This entire supply was pasteurized with the exception

of 500 gallons certified under the Milk Commission of the County Medical Society and 455 gallons from the guaranteed raw milk dealers.

The Health Committee voted against the ordinance 2 to 1 but a minority report by the chairman of the committee brought the ordinance before the Board of Supervisors as a whole. For 20 weekly meetings, over a period of 5 months, arguments for and against were heard. Various protests and arguments were heard from the National and the California Natural Milk Producers Associations. These long-drawn-out and often inaccurate dissertations were fortified by personal accusations against the integrity of the Director of Public Health and his staff of milk inspectors. A mythical milk trust was painted as a *bête noire* threatening the future price of milk. This threat was based on the plea of one man who produced 50 gallons a day and who alleged that the elimination of his product would inevitably produce a monopoly. Women's clubs, civic organizations, the County Medical Society, and the Health Advisory Board, now an advisory committee, were all solidly behind the ordinance when finally the opponents of the measure gave up trying to wear down its sponsors and permitted a vote to be taken. The measure passed and the opponents had not gained a single vote.

On May 1 the measure passed its second reading and became effective May 15. The clause in reference to milk for cream separation has a 60-day delay before becoming operative.

San Francisco is to be congratulated on the fact that its Board of Supervisors is willing to listen to expert advice, and recommendations not based on commercial motives in passing laws which safeguard the health of the citizens and the children of San Francisco.

DIFFERENTIATION OF HUMAN FROM BOVINE TUBERCLE BACILLI

A TIMELY warning concerning the use of the rabbit as an animal for the differentiation of the bovine and human types of the tubercle bacillus has been given by Cobbett.¹ It will be remembered that in Koch's memorable address at the London Congress on Tuberculosis, in 1901, he said that the proper method of differentiation was inoculation of the bovine animal, and in the first experiments, those done at the State Live Stock Sanitary Board of Pennsylvania, a grown cow and calves were used. Necessarily the expense was heavy, and it was a great relief to bacteriologists to find that the rabbit was almost as good an animal for the differentiation of these two types of organism as cattle. Since that time, the work, as far as animal inoculation goes, has been done largely with rabbits. Dr. Cobbett considers that we have assumed too much regarding the immunity of the rabbit toward the human type of the tubercle bacillus, and points out that general infections do take place, and the animals sometimes die. The immunity is therefore only relative.

He gives an interesting description of the two types of tuberculosis seen in rabbits following inoculation with the human strain of the bacillus, and ends by warning experimental workers that they must recognize " (a) an extensive mild type of tuberculous peritonitis with some degree of miliary tubercle of the lungs in rabbits which have been injected intraperitoneally with human strain, and

(b) occasionally severe progressive lesions in various organs, particularly testes and joints but sometimes also lungs." If any doubt should arise, further inoculation experiments may be necessary to arrive at a definite conclusion.

This work has raised certain interesting questions. The extensive work of Villemin in 1865 was done with tuberculous material from various sources, the bacillus not having been isolated at that time. In other words, it is almost certain that mixed cultures were used, and there are certain diseases, tetanus for example, in which often a mixed culture produces more decided effects than a pure one. However, Villemin unquestionably produced tuberculosis in rabbits by the use of human material, and decided from his experiments that tuberculosis in whatever form or in whatever animal found, was one and the same disease. In his first experiment he inoculated 9 rabbits with human material, and produced tuberculous lesions in all. Later and more extensive experiments confirmed his results, but he found that bovine material was much more virulent for rabbits than human. He even said that bovine tubercle was virulent for rabbits, human for guinea pigs.²

In 1882, Koch gave his memorable address on the etiology of tuberculosis, using pure cultures for his inoculation experiments. In Experiment 11,³ he obtained generalized tuberculosis in rabbits by the injection of cultures from several sources, one obtained from human lungs, and one from spontaneous tuberculosis in a monkey, which was probably of human origin. The injections were made by several methods.

The question arises "How did these infections take place?" There can be no question that the observations were accurate. Did Villemin and Koch accidentally obtain organisms of the human type of greater virulence than usual, or had the subjects from which the material, in the one case, and the cultures in the other, were obtained been originally infected with tuberculosis of the bovine type? It is an interesting question for you to speculate upon.

CONSERVATION OF WATER

WITHOUT proof, we accept the fact that good water is essential to the individual and the community. We must have it to maintain life and habitable surroundings; therefore, it is proper that such water procurement plans as are deemed necessary should be carried through to successful conclusions. Yet, how often have municipalities been forced to go great distances at large expense for an adequate supply of good water when a much closer source would have been available if only it had been preserved and protected in such manner as to keep it suitable for consumption! Quite a number of instances of this kind can be recalled.

Misuse of a supply of good water today may mean regret tomorrow. Changing conditions sometimes bring about sudden growth in cities which forces the augmenting of the public water supply. Hence, today is the time to look ahead to

future needs. Such foresight and the good effects usually resulting therefrom will often save a good water supply which later would have to be allotted to lower uses on account of earlier misuse.

This country has been criticized as being a profligate one. In our use and misuse of our great natural resource—water—this is probably just criticism. It is strange that this is true for we have had the benefit of the experience in other countries, such as England.

Today, when the keynote is economy without sacrifice of real efficiency, it behooves us to stop and take stock of our water resources. Maryland, a state which in the past has given but little attention to the quantity of water flowing out of and over its territory, has recently created a Water Resources Commission to study the underground and surface supplies with a view to formulating plans for their preservation, allocation, control, and regulation. Other states have been working on such a program for some years but many have done nothing. In those states, now is the time to act—before denser populations with more extensive use and abuse further complicate the problems.

We must have good drinking water. Why not preserve and protect what is now available?

THE WESTERN BRANCH MEETING

THE Fourth Annual Meeting of the Western Branch of the American Public Health Association was held in Pasadena, Calif., May 29, 30 and 31. It was the largest meeting held up to date, there being more than 500 registrations, and almost as many visitors in attendance. Unfortunately very few of the eastern members could be present.

The scientific program was full and well selected, more than 30 papers having been presented. A resolution was passed unanimously asking the parent society, the American Public Health Association, to meet in Southern California in a joint session in the fall of 1934. It is about time for the Association to meet in the West again and it is to be greatly hoped that this plan can be carried out.

Dr. J. L. Pomeroy, of Los Angeles, was inducted as President, and Dr. Walter H. Brown, of Palo Alto, was made President-Elect.

Sixty-second Annual Meeting of the American Public Health
Association, Indianapolis, Ind., October 9-12, 1933,
Headquarters, Claypool Hotel

*Indiana World War Memorial as Seen from the Top of the Federal Building
in Indianapolis*

ASSOCIATION NEWS

INDIANAPOLIS—OCTOBER 9-12

SOME OF THE PLACES OF SCIENTIFIC INTEREST WHICH DELEGATES
TO THE ANNUAL MEETING WILL VISIT

THE local Committee in charge of arrangements for the Association's Sixty-second Annual Meeting is planning an extensive program of inspection trips, since there is much to interest health workers in Indianapolis.

Everyone will wish to spend some time at the Indiana University Medical Center. This occupies a 40-acre tract of land, and includes the following units: The School of Medicine, the Training School for Nurses, the Robert W. Long Hospital, the James Whitcomb Riley Hospital for Children, the William H. Coleman Hospital for Women, and the School of Dentistry, the building of which is under construction at the present time. In November, 1931, the Indiana Rotary Convalescent Home

for Children was opened and is regarded as a unit of the James Whitcomb Riley Hospital for Children. All of the above hospitals are state hospitals under the control of Indiana University.

The Indiana University School of Medicine was organized at Bloomington in 1903. In 1907 the Indiana University School of Medicine and the State College of Physicians and Surgeons united under the name of the Indiana University School of Medicine. In 1908 negotiations were completed whereby the Indiana Medical College was united with the Indiana University School of Medicine under the name of the latter and in 1909 an act was passed by the legislature authorizing the Trustees of Indiana University to

conduct a Medical School in Marion County at Indianapolis. The first year of the four years' medical course is given only at Bloomington and the last three years are given only at Indianapolis. The enrollment in the past few years has averaged approximately 100 in each class.

The Indiana University Training School for Nurses is housed in the Ball Nurses' Home. Including affiliate and post-graduate students, the enrollment is approximately 200.

The Robert W. Long Hospital, opened in 1914, is a general hospital built especially to serve patients of the rural and small town districts of the state where hospital facilities are not available. The normal capacity of the Long Hospital is 107 beds, 18 of which are in private rooms. An extensive

out-patient service is conducted. Private cases, full-pay ward, part-pay ward, and charity cases are accepted at the hospital. The Long Hospital is maintained by means of a state appropriation and by patients' fees.

The James Whitcomb Riley Hospital for Children, opened in 1924, accepts patients from the state whose parents are financially unable to provide for hospital care. Each child admitted to the hospital must be committed to the hospital by the Judge of the County in which the parents have established legal residence, and the cost of the care and treatment of the patient is paid by that County. The hospital

also receives a small state appropriation. An extensive out-patient service is extended to those patients not requiring hospitalization. Two major additions have been made to the Riley Hospital since its opening: In January, 1930, the Kiwanis Wing, the gift of the Kiwanis Clubs of the state, was opened to patients. This ward has a

capacity of 50 beds and is devoted to the care of orthopedic cases. In November, 1931, the Indiana Rotary Convalescent Unit, the gift of the Rotary Clubs of the state, was opened for patients. The Convalescent Unit, having a capacity of 60 beds, is located adjacent to the Riley Hospital and offers a most beneficial service to the patients of the Riley Hospital.

The William H. Coleman Hospital for Women, opened in 1927, is devoted

Obelisk and Illuminated Fountain in the Indiana World War Memorial Plaza, Indianapolis, Ind.

to the care of obstetrical and gynecological cases. The service of this hospital is extended to the state, and private cases, full-pay ward, part-pay ward, and charity cases are accepted. The normal capacity of the Coleman Hospital is 103 beds, which includes 35 bassinets. Twenty-seven of the adult beds are in private rooms. An out-patient department is conducted. In addition to the regular clinics, a Well-Baby Clinic is conducted. The maintenance of the Coleman Hospital is provided by a state appropriation and patients' fees.

If the cordial invitation of the Indianapolis Water Company to inspect

its various plants is accepted, delegates will see the unusual picture of a slow sand and a rapid sand filter plant handling the same raw water.

Both the main filter plant and the main pumping station of the Indianapolis Water Company are located close to the downtown section of the city and can be reached by motor within 15 minutes.

Indianapolis pioneered in the United States with filter plants. In 1904, when the slow sand filters were placed in service, filter plants had not been installed in St. Louis, Detroit, Washington, Philadelphia, Pittsburgh, and many other principal cities. Now entering the 30th year of their continuous service, all 6 units of the slow sand filter are giving very satisfactory operating results.

The rapid sand filter plant was installed in 1926. Each of the 6 units has an area of 721 square feet. Both the rapid and the slow filters handle water that has undergone preliminary treatment.

Public health engineers and members of the Laboratory section will find especially interesting:

The method of unloading, storing, and feeding of coagulants, involving the use of conductivity recording equipment.

A new plant for handling liquid chlorine in ton containers.

Equipment for applying ammonium sulfate in taste control.

Many unusual devices in the control laboratory.

The laboratory at the company's filter plant was started in 1903. At present the routine involves the handling of about 50,000 samples of water annually, ranging from the raw water through all stages of treatment to various points in the distribution system.

Since 1904, when the present system of safeguarding the city's public water supply was completed, the U. S. Public

Health Service has never failed to certify Indianapolis water.

An inspection of the sanitary district of Indianapolis will prove interesting to delegates.

The Sewage Treatment Plant was put into service in 1925. It consists of the following units or processes:

1. Grit Chambers. One main, three-channel, one two-channel and two three-channel grit chambers all fitted with bar racks and, the larger ones, with grease skimmers. They are located ahead of inverted siphons at river crossings and deliver, through conduits, to a common channel entering the clarification plant.

2. Clarification Plant. The fine screens have $1/16"$ x $2"$ slotted openings. Three screens operate in each channel. Sewage entering them is discharged at the end. Solids, larger than the openings, are left behind in the channel and carried out to sedimentation basins by one-third of the sewage flow, two-thirds of it having passed through the screens. The screens act as concentrators, none of the material being removed on them. The sludge from the rectangular settling basins is pumped to the digestion pits.

3. Activated Sludge Plant. The first spiral circulation in America was at Indianapolis. Since the Indianapolis plant went into service, it has been general practice to include this feature. The settlers are circular. The mechanism was designed by the engineer without the use of patented features. The plant treats about 70 per cent of the sewage flow. At the time of construction, insufficient money was available to build a larger plant. Its completion has been under consideration for some time. Unusual methods of operation have been used to relieve the river as much as possible.

4. Sludge Disposal. Both primary and activated sludge are digested in open pits about 300 feet square and 10-14 feet deep. No drying beds are provided. The wet sludge is used on market gardens, being applied in the winter so that freezing disintegrates it. The partially equipped dehydration unit was operated for six months in 1931 but is idle on account of lack of money to complete and operate it.

5. The Garbage Disposal Plant is operated by the same Board and is located adjacent to the Sewage Plant. Garbage is collected weekly in winter and bi-weekly in summer in motor drawn trailer trains and delivered to a receiving pit at the plant. Conveyors deliver it to the pressure cookers in which it is cooked

for 2.5 hours at 80 lb. pressure. The free grease is drawn off and the mass drained and dried in the cooking tank under vacuum. The finer, lighter part of the dried tankage is separated by the use of an air current and sold for feed. The residue is percolated to recover the grease, after which it is sold as fertilizer. The grease is sold for soap making and represents the most valuable part of the by-products.

Members will have the opportunity to visit the extensive laboratories of Eli Lilly and Company. The group of 25 major buildings covers several city blocks and comprises scores of departments. In addition, biological laboratories, with commodious horse stables and comfortable quarters for small animals, are maintained on a farm 20 miles east on the National Highway.

Research primarily directed to the discovery of new and better therapeutic agents or the improvement of those now

in use is conducted throughout the year at the Indianapolis laboratories of the company, and the biological plant. The personnel of the scientific division has grown, since it was first organized in 1886, until now it includes over 70 research workers trained in chemistry, biology, bacteriology, physiology, pharmacology, and experimental medicine. Approximately 40 of this corps devote their entire time to research problems. The Lilly research staff is in constant coöperation with investigators in universities, clinics, and hospitals in the United States and in many foreign countries.

The above represents only a few of the interesting possibilities in Indianapolis.

The Local Committee will have further plans to report in the next issue of this Journal.

ANNOUNCEMENT OF THE 1933

Inter-Chamber Health Conservation Contest

THE CHAMBER OF COMMERCE OF THE UNITED STATES hereby announces the fifth inter-chamber health conservation contest in conformity with a resolution adopted at its 17th annual meeting.

The PURPOSE of this contest is to interest the business man in public health and thereby assist in the intelligent fostering and promotion of sound public health practices.

The ENROLLMENT procedure consists of the filling out of the attached entry blank by the secretary of the local chamber of commerce and the forwarding of it to the Insurance Department of the Chamber of Commerce of the United States at Washington, D. C.

The only REQUIREMENT for enroll-

ment is that a community's local chamber of commerce be affiliated with the National Chamber.

The FACT-FINDING SCHEDULE is the form upon which cities are graded and this is due in Washington on or before March 1, 1934.

Further data on the Contest are available either from the Insurance Department, Chamber of Commerce of the United States, Washington, D. C., or the Committee on Administrative Practice, American Public Health Association, New York City.

May 25th, 1933.

Early Enrollment Preferably by July 1 will be to the Advantage of Your City!

HOTEL RESERVATION BLANK FOR INDIANAPOLIS MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION

450 SEVENTH AVENUE, NEW YORK, N. Y.

OCTOBER 9-12, 1933

To
(Name of Hotel)

Please reserve for merooms for.....persons
for the A.P.H.A. Meeting.

Single room.....Double room.....

Maximum rate per day for room \$.....Minimum rate per day for room \$.....

I expect to arrive..... If date of arrival is changed I will notify
you at least 24 hours in advance.

Please acknowledge this reservation.

Name

Street address

City..... State.....

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- Hubert M. Heitsch, M.D., Pontiac General Hospital, Pontiac, Mich., Director of Public Health
 George M. Little, M.D., D.P.H., Red Deer, Alta., Canada, Medical Officer of Health
 Harry L. Richardson, B.S., Daytona Beach, Fla., Health Officer

Laboratory Section

- Clinton F. Brown, Chemical Laboratory, City Hall, Trenton, N. J., Assistant City Chemist

Public Health Engineering Section

- Charles H. Capen, Jr., 8 Florence Pl., West Orange, N. J., Sanitary Engineer, Water Filtration Plant
 Bryant W. Richardson, 17 King St., Painesville, O., Design of Sewage Disposal Plants
 Carl J. Scheldrup, B.A., City Hall, Albert Lea, Minn., City Health Inspector

Child Hygiene Section

- Garner M. Byington, M.D., W. K. Kellogg Foundation, Battle Creek, Mich., Associate Medical Director
 Emory Morris, D.D.S., W. K. Kellogg Foundation, Battle Creek, Mich., Director, Dental Education
 Lulu St. Clair, R.N., W. K. Kellogg Foundation, Battle Creek, Mich., Director, Health Education

Food and Nutrition Section

- Samuel Weiss, M.D., 57 W. 57 St., New York, N. Y. (Assoc.)

Public Health Education Section

- James M. Anders, 250 S. 17th St., Philadelphia, Pa., Member, Board of Health

- Etta E. Giddens, R.N., 31 Audubon Rd., Boston, Mass., with City Health Department

- Theda L. Waterman, R.N., 905 Garland St., Flint, Mich., Executive Secretary, Genesee County Tuberculosis Assn.

Public Health Nursing Section

- Lovina R. Chase, R.N., P. O. Box 322, Fishers Island, N. Y., Public Health Nurse
 Violet S. Hoar, R.N., W. K. Kellogg Foundation, Battle Creek, Mich., Health Teacher
 Florence B. Ryan, R.N., 54 E. Myrtle St., Orange, Mass., Public Health and School Nurse

Epidemiology Section

- Roy F. Feemster, M.D., Dr.P.H., Dept. of Public Health, State House, Boston, Mass., Assistant Director, Division of Communicable Diseases
 Huldah E. Thelander, M.D., 822-39 Ave., San Francisco, Calif., Assistant in Communicable Disease Department, Children's Hospital

Unaffiliated

- James V. May, M.D., Room 109, State House, Boston, Mass., Commissioner, Mass. Dept. of Mental Diseases
 John E. Runnells, M.D., Bonnie Burn Sanatorium, Scotch Plains, N. J., Superintendent

Sustaining Member

- Life and Casualty Insurance Company of Tennessee, Life and Casualty Bldg., Nashville, Tenn.

DECEASED MEMBERS

- Leon C. Havens, M.D., Montgomery, Ala., Elected Member 1920, Fellow 1931
 James R. McClintock, B.S., New York, N. Y., Elected Member 1919, Fellow 1922
 Lydia Clark, Columbus, O., Elected Member 1928
 H. L. B. Coote, M.D., Michigan City, Ind., Elected Member 1915
 F. C. E. Mattison, M.D., Pasadena, Calif.,

- Elected Member 1910, Fellow 1930
 William C. Cotton, Atwater, Calif., Elected Member 1931
 G. Webster Hallett, Osterville, Mass., Elected Member 1929
 Dr. Ernest A. LeBien, McHenry, N. D., Elected Member 1931
 Irving D. Williams, M.D., New York, N. Y., Elected Member 1919.

APPLICANTS FOR FELLOWSHIP

HEALTH OFFICERS SECTION

John W. Brown, M.D., C.P.H., Austin, Tex.
Joseph Howard Hickson, M.D., New Haven, Conn.
Arthur D. Knott, A.B., M.D., D.P.H., Parkersburg, W. Va.

LABORATORY SECTION

Conrad Kinyoun, A.B., Savannah, Ga.
Walter Leroy Kulp, M.S., Ph.D., Storrs, Conn.
Newton W. Larkum, B.S., Ph.D., Lansing, Mich.

VITAL STATISTICS SECTION

Lloyd Rolland Gates, M.S., D.P.H., Ann Arbor, Mich.
Jessamine S. Whitney, A.B., New York, N. Y.

PUBLIC HEALTH ENGINEERING SECTION

Albert E. Berry, M.A., C.E., Ph.D., Toronto, Ont., Canada
William Roscoe Berry, Norfolk, Va.
Harold Stephens Hutton, C.E., Montclair, N. J.
W. Scott Johnson, A.B., M.S., Jefferson City, Mo.
Willis Taylor Knowlton, B.S., Los Angeles, Calif.
Charles Lundy Pool, S.B., Providence, R. I.
Frank Russell Shaw, C.E., Chicago, Ill.

CHILD HYGIENE SECTION

Mary Ella Chayer, B.S., New York, N. Y.
Joseph F. Paulonis, Ph.G., M.D., Brooklyn, N. Y.

Charles Joseph Prohaska, M.D., Hartford, Conn.
Eldred Victor Thichoff, M.A., M.D., Cleveland, Ohio

FOOD AND NUTRITION SECTION

Ferd. A. Korff, B.S., Baltimore, Md.
Bernard Emerson Proctor, S.B., Ph.D., Cambridge, Mass.

PUBLIC HEALTH EDUCATION

Mrs. Bertha M. Ashby, B.S., M.S.P.H., Norman, Okla.
George A. Dundon, B.J., Milwaukee, Wis.
Baxter Key Richardson, A.B., Springfield, Ill.
John P. Sullivan, A.M., Ph.D., Boston, Mass.
Carl A. Wilzbach, B.S., M.D., Cincinnati, Ohio

PUBLIC HEALTH NURSING

Ruth P. Carroll, A.A., B.S. in Ed., R.N., Houston, Tex.
Netta Ford, R.N., York, Pa.

EPIDEMIOLOGY

H. Jackson Davis, A.M., M.D., Dr.P.H., Albany, N. Y.
Kenneth Fuller Maxcy, B.A., M.D., Dr.P.H., Charlottesville, Va.

UNAFFILIATED

Bertram Feuer, M.S., Ph.D., Chicago, Ill.
George Henry Roth, M.D., Los Angeles, Calif.
Nicholas Francis Williams, D.V.S., Fort Worth, Tex.

VITAL STATISTICS INSTITUTE PROPOSED FOR 1934

THE Vital Statistics Section of the American Public Health Association, at the suggestion of the Committee on Meetings and Publications, has been studying the desirability of a Vital Statistics Institute at the annual meeting. The Section Secretary, Dr. A. W. Hedrich, has sent a list of proposed subjects to a large number of Vital Statistics Bureaus with a view to determining which were of greatest interest to the membership. The replies were thoughtful and illuminating, and

indicated a pronounced interest in the project. For various reasons it has been deemed best to hold the Institute at the 1934 annual meeting.

Meanwhile, the officers are completing plans for a successful annual meeting at Indianapolis, in preparation for which the Section Council has held two meetings thus far. An outstanding feature of this year's meeting will be a joint session with the Health Education Section on the use of vital statistics in health-education.

FREDERIC POOLE GORHAM, 1871-1933

FREDERIC POOLE GORHAM died in the garden of his summer home at Glocester, Rhode Island, on June 4. A member of this Association since 1899 and one of its original Fellows, his passing leaves in his associates a sense of the deepest loss.

His influence, exerted unostentatiously in countless directions, has left its permanent impress upon the science of his chosen profession, Bacteriology. Identified with the inauguration of Standard Methods for Water Analysis and Shell Fish Examination, he has been associated with all of their subsequent revisions.

Forty years ago he was appointed to the Faculty of Brown University as a Zoölogist. He soon added to his duties the development of courses in Bacteriology which comprised some of the earliest formal instruction in this subject in this country. At the time of his death he was Professor of Bacteriology and head of the Department of Biology. In the opinion of his colleagues he was one of the great teachers of his generation.

As one of his former pupils, I would add a personal tribute. We were fond of "the Prof.", but, in student days, not cognizant of his effective service in our behalf. We did not then know, as we now perceive, that he was continually working upon his boys and bringing out what might be in them. There was little of "spoon-fed" pedagogy in his graduate courses. Without our knowledge, we were being taught to stand on our own feet, and only in after years has it become apparent with what friendly artistry he did that thing which it is so difficult to do for students.

His interest in his fellow men colored his every activity. Thirty-five years ago he took the first smears for the diagnosis of diphtheria in patients of the health department of his native city, Providence. Dr. Chapin has styled this

as the beginning of practical bacteriology in his department. The association of these two scientists in this work was continued until interrupted by death. For the State of Rhode Island he saved the failing shellfish industry by the planned and supervised investigations which resulted in the necessary sanitary reforms. When the milk situation in his community needed scientific attention, Gorham was prevailed upon to take over the work, and he accomplished results which won for him the praise of all concerned. Mosquito eradication he directed successfully; hospital and community welfare projects benefited by his sound judgment and advice; in a truly remarkable way he discharged the civic duties of the individual and exemplified the service of science to the community.

As would be expected of a scientist of such wide interests, Professor Gorham was a member of many learned societies, among which the Society of American Bacteriologists benefited by his services as secretary, vice-president, and president.

It is a fine thing so to have lived that even after death has come one lives on in the affection and esteem of his fellow men. Professor Gorham possessed so many admirable qualities that it is difficult to know which most to admire. Be it his genial smile, his pithy eloquence, his great adaptability, his indefatigable industry, his unfailing interest in mankind, his skill as administrator, organizer, teacher, his keen analysis of problems and equally keen formulation of methods for seeking their solution, his tremendous volume of quiet accomplishment, each and every one of these was a manifestation of his friendliness, enthusiasm, competence and integrity. What more can any man possess and share with his generation? JOHN W. M. BUNKER

EARL MAX PICKENS

EARL MAX PICKENS, A.M., D.V.M., Fellow and Secretary, Food and Nutrition Section, American Public Health Association, succumbed to a heart attack on June 13th, 1933. Dr. Pickens was Professor of Bacteriology and Animal Pathology and Head of the Department at the University of Maryland, College Park. He was 44 years old.

He had long been active in public health work, particularly as related to

milk and animal diseases. He was known as a capable investigator, a successful teacher and one who gave much time and thought to state and national health problems. He has been honored by election to responsible offices in several scientific organizations to which he belonged.

The Association has lost an influential member and an ardent supporter. Dr. Pickens' wife and three children survive him.

A NATION'S INVESTMENT IN HEALTH

DR. FRED O. TONNEY, of Chicago, for many years head of the research staff of Chicago and also radio advisor to the Association, is introducing on June 28 a series of radio broadcasts through the facilities of the National Farm and Home Network of the National Broadcasting Company sponsored by the American Public Health Association. The program has been arranged by a committee under

the direction of Dr. Louis I. Dublin, past president of the Association, Dr. John A. Ferrell, Dr. Haven Emerson, Dr. Kendall Emerson, and Dr. Fred O. Tonney, together with the active coöperation and help of Mr. Frank E. Mullen of the National Broadcasting Company. The speakers have been carefully selected and the program arranged is as follows:

| <i>Date 1933 - Subject</i> | <i>Name</i> | <i>From</i> | <i>Time (Daylight saving)</i> |
|--|------------------------|-------------|-----------------------------------|
| June 28 Introduction | Dr. Fred O. Tonney | Chicago | 12:35 P.M. C.D.T. |
| July 5 Water Control | George W. Fuller | New York | 1:35 P.M. E.D.T. |
| July 12 Protection of Milk Supplies | Dr. Chas. E. North | New York | 1:35 P.M. E.D.T. |
| July 26 Reduction in Public Health Budgets | Dr. Kendall Emerson | New York | 1:35 P.M. E.D.T. |
| Aug. 2 To be selected | Dr. Herman Bundesen | Chicago | 12:35 P.M. C.D.T. |
| Aug. 9 Safeguarding Child Life | Dr. George Palmer | New York | 1:35 P.M. E.D.T. |
| Aug. 23 Epidemiology | Dr. George B. Ramsey | New York | 1:35 P.M. E.D.T. |
| Aug. 30 Laboratory Chats | Dr. Fred O. Tonney | Chicago | 12:35 P.M. C.D.T. |
| Sept. 6 Tuberculosis | Dr. Lawrason Brown | New York | 1:35 P.M. E.D.T. |
| Sept. 13 To be selected | Dr. Louis I. Dublin | New York | 1:35 P.M. E.D.T. |
| Sept. 27 Safeguarding Infant Life | Dr. Alfred E. Hess | New York | 1:35 P.M. E.D.T. |
| Oct. 4 Causes and Results | Prof. C.-E. A. Winslow | New York | 1:35 P.M. E.D.T. |

The committee wishes to take this opportunity to thank Dr. Tonney for the work he has done in arranging and handling the details of this broadcast with the Broadcasting Company and to thank Mr. Mullen for the opportunity

given us by the National Broadcasting Company to bring before the public many of the problems of public health and to present them in a scientific and authoritative manner.

PUBLIC HEALTH ADMINISTRATION

Salem, Mass.—This city with a population of 43,353 (1930 census) reports a death rate of 10.9 for 1932. The infant mortality rate has consistently declined from 189 in 1900 to 64 in 1930 and reached a new low figure of 43 per 1,000 births in 1932. Diphtheria prevention clinics have been conducted in the schools but the Board of Health reports that diphtheria is more prevalent than it should be. There were 54 cases with but one death. The Health Department personnel includes, in addition to the Health Officer, one clerk, one physician, one dentist, one inspector of animals, two public health nurses and two sanitary inspectors.

Lynn, Mass.—This city of 102,320 individuals (1930 census) reports a death rate of 10.2 for 1930, slightly higher than that for the preceding year. The health department budget was \$51,562.00. There were reported 57 cases of diphtheria with 3 deaths.

Indiana.—The State Board of Health of Indiana, which recently celebrated its fiftieth anniversary and could boast of only 5 health commissioners during that period, has been reorganized and Dr. John H. Hare, a member of the old State Board of Health, has succeeded Dr. William F. King, as Secretary. The work of the maternal and child welfare division has been discontinued except in its strictly educational phase. Laboratory service has been transferred to the University School of Medicine. State support for venereal disease clinics has been withdrawn. The new form of organization provides for closer relation between the State Board of Health, the State Uni-

versity and the State Medical Association.—*Month. Bull.*, Indiana State Board of Health, Apr. 1933.

Venereal Disease Clinics.—The New York State Department of Health states that a community should have a clinic when such "community can care for its indigent syphilitics at less cost by providing clinic service than by paying physicians a nominal fee per visit for the medical supervision of such cases." There is need of economic consideration for the care of indigent persons afflicted with syphilis who are apparently applying for medical care in ever increasing numbers. Responsibility for treatment of such individuals rests upon the local boards of health and health officers.

The social hygiene division of the State Health Department is assisting in presenting the need for clinics to county medical societies and county boards of supervisors.—*Health News*, New York State Dept. of Health, May 15, 1933.

Knoxville, Tenn.—This city with an estimated population of 111,930 in 1932 spent \$.51 per capita for public health purposes. The per capita expenditure has shown a decrease from \$.64 in 1930. The death rate of 12.1 is the lowest on record. A very encouraging report is made of the reduction in the so-called filth-borne diseases including diarrhea and enteritis, which causes have long been prominent in the leading causes of death. Diarrhea and enteritis now stands tenth on the list and is responsible for but 2.4 per cent of all deaths. The annual health report which is multigraphed is very attractively edited and contains numerous

valuable charts, tables and diagrams. The Health Officer has well demonstrated what can be done with the limited appropriation and facilities.

Schenectady, N. Y.—This city reports a death rate of 10.65 for 1932. There has been a general reduction in the number of reported cases of communicable diseases with the exception of mumps, which showed some increase and whooping cough which showed a marked increase. The infant mortality rate was 80 and the birth rate 16. Two deaths were attributed to diphtheria. The annual report contains statistical tables and tabulations on inspections and services rendered in the various divisions of the Department.

Chicago, Ill.—In May, 1914, a comprehensive ordinance was passed creating a Board of Health of 5 members. For many years prior to 1932, according to the ruling of the State Supreme Court, Chicago had been without a legally authorized health department; one which possessed the necessary authority to enforce the health laws and protect its citizens in case of epidemic or emergency. With the advent of the new Board, there has been developed a complete reorganization of the functions and personnel of the department. With a general death rate of 9.8 a new low record has been established. This means that 953 fewer persons died in 1932 than in 1930, the year of previous lowest record. The diphtheria death rate has dropped from 6.2 in 1931 to 1.9 in 1932, a decrease of 71 per cent. During the same time

the infant mortality rate has been lowered from 56.4 to 48.8. Chicago continues its unique record for a low typhoid fever rate, that for 1932 being 0.4.

A special educational program was carried on to increase the per cent of preschool children protected against diphtheria. A publicity program included the release of nearly 2,000,000 pieces of literature dealing with diphtheria protection. Field nurses were employed to urge parents to take children to the family physician. The "Birthday File," which now contains nearly 300,000 names, was used effectively, as were the infant welfare stations and the public and parochial schools. One of the special features was a motorized diphtheria prevention clinic which travelled to various areas in the city where the per cent of protection was low.

Prior to the end of the school year in June, 25 physicians and 25 nurses were paid by the Municipal Tuberculosis Sanatorium for school health service but since that date this work has been transferred to the Department of Health and there are now 35 school health officers in the Bureau of Child Welfare. In this bureau there has been an average of 300 nurses engaged during the last 3 months of the year.

There were 565 health talks given during the year by the personnel of the Board of Health, of which 75 were devoted to diphtheria, 47 on child hygiene, 64 on dental hygiene, 16 on food control, 25 for milk control, 112 on laboratory topics and 84 on general sanitation.

LABORATORY

THE USE OF GLYCEROL AS A PRESERVATIVE FOR MILK SPECIMENS TO BE EXAMINED FOR HEMOLYTIC STREPTOCOCCI

RUTH GILBERT, M.D., F.A.P.H.A. (*Life Member*), and M. E. CLARK
Division of Laboratories and Research, New York State Department of Health,
Albany, N. Y.

WHEN epidemics of septic sore throat are investigated, samples of milk submitted for laboratory examination may be in transit several days. During this time, in summer particularly, saprophytic strains of bacteria may multiply so rapidly that hemolytic streptococci, if present, are difficult to isolate. The efficient preservative action of glycerol on material containing microorganisms of the enteric disease group¹ and on milk to be examined for *B. abortus*² suggested its use also in milk to be examined for hemolytic streptococci.

A one-third volume (approximately 30 per cent) of glycerol of tested purity was added to samples of milk which had been recently collected. The specimens were then inoculated with strains of hemolytic streptococci from cases of septic sore throat. After 7 days at room temperature or 10 days in the refrigerator, the microorganisms could be easily isolated, while they were recovered with difficulty after 24 hours at room temperature from similarly inoculated portions of the milk samples which contained no glycerol. An equal volume of glycerol—50 per cent—proved less satisfactory since, under these conditions, the colonies of strep-

tococci which developed on the plating medium were slightly fewer than those from specimens containing a 30 per cent concentration; 20 per cent of glycerol has usually sufficed to preserve the specimens for 2 days only, when they were kept at room temperature.

During the past 2 years, approximately a one-third volume of glycerol has been added to samples of milk sent to be examined for streptococci; green-producing as well as hemolytic streptococci have been easily isolated from such specimens.

A simple outfit containing a measured amount of glycerol of tested purity is used. By means of a label pasted on the container to indicate the level to which the milk should be added, a 30 per cent concentration of glycerol is secured. After collection, the specimen container should be well shaken to insure thorough mixing of the glycerol and the milk.

A STUDY OF THE BROM-THYMOL-BLUE REACTION IN FRESHLY DRAWN MILK*

C. S. BRYAN

*Section of Bacteriology, Michigan Agricultural Experiment Station,
East Lansing, Mich.*

THE use of indicators in the detection of abnormal milk began with the investigations of Van Slyke and Baker.¹ It was primarily their purpose to detect abnormal or altered market milk and not the detection of milk from diseased udders. The following year Baker and Breed² studied various indicators in milk for the detection of mastitis. Within the past few years Stableforth,³ Rosell,⁴ Udall and Johnson,⁵ and Hucker⁶ have used the brom-thymol-blue reagent in the detection of milk from udders affected with mastitis. Sharp and McNery⁷ found the brom-thymol-blue indicator gave such a large error as to make it practically useless. Stableforth³ in his studies of pH of milk samples as affected by fat content reports, stated that

From the extract, of the results given in Table II, it can be seen that, taking 3 per cent as a standard, although a variation of 0.5 per cent makes little difference, a variation of 1 per cent so alters the color as to interfere considerably with the accuracy of the test; while one of two per cent makes the test nearly valueless, because a sample might be regarded as normal, doubtful, or abnormal merely according to the percentage of fat.

"Thyromol" outfits, for the detection of milk from quarters affected with mastitis, have recently appeared on the market. These are merely convenient field apparatus using brom-thymol-blue indicator to determine the pH of freshly drawn milk. There has been

wide adoption of these outfits by large milk companies in their inspection work and also by a large number of veterinarians in private practice. The present study was made to determine the significance of unexplainable variations of this test, which had been brought to our attention.

The technic used in this work was that recommended by Udall and Johnson,⁵ which was adopted by the commercial concerns for their "Thyromol" outfits. The tests were made on the freshly drawn milk from the individual quarters and were recorded as either positive (+), doubtful (\pm), or negative (-). Positive reactions represent milk of pH 7.0 or alkaline, doubtful approximately pH 6.9, and negative pH 6.5. These groupings were based on the work reported by Hucker.⁶

DATA AND DISCUSSION

The data present the brom-thymol-blue reactions as obtained, over a period of 5 to 6 months at monthly intervals, under three different conditions. These are: (1) The normal or physiological variation of the pH of the milk of mastitis-free animals. All of the infected animals in this herd had been slaughtered 4 years previously; (2) the constancy of positive reactions in naturally infected animals; and (3) the variation from a negative reaction of non-infected animals that are present in an infected herd.

The study of normal variation of the pH of non-infected animals was carried

* Journal Article No. 157 (n.s.) from the Michigan Agricultural Experiment Station.

out in a disease free (mastitis, tuberculosis, and abortion) herd. Four years previously a complete cleanup was made and all infected animals were slaughtered; this was followed by disinfection and renovation of the barn. During the past 4 years there have been no udder disturbances whatsoever. Very few animals have been purchased and placed in this herd. Bacteriological examinations of the milk and physical examinations were made of the milk and udders, at several weekly intervals, before such animals were released from the quarantine barn.

The results of the brom-thymol-blue reactions of the milk from these mastitis-free animals are presented in Table I. Of the 33 lactating animals there were 7 that showed a variation in reaction of the milk during this study. The reactions of the 26 animals which gave consistently negative (—) tests are not recorded in the table. The data show that a definite and pronounced variation is obtained in the pH of freshly drawn milk from these mastitis-free animals. These positive or doubtful reactions occur sporadically and may change from quarter to quarter in the same cow, e.g., a positive or doubtful reaction may be obtained and then not recur in the same quarter or cow during the period of this study. These variations occurring from time to time in mastitis-free animals demonstrate the limitations of a diagnostic test based on the pH of freshly drawn milk.

To determine the constancy of positive reactions in the milk of infected animals several naturally infected animals were chosen. The results are given in Table II, cows A and B. It will be noted that at each examination streptococci of mastitis were cultured from all four quarters of cow A. The pH reactions showed a progressive reaction and became more positive throughout the period of this study. In only

TABLE I

BROM-THYMOL-BLUE REACTIONS OF FRESHLY DRAWN MILK FROM INDIVIDUAL QUARTERS OF COWS IN A MASTITIS-FREE HERD. THE 7 COWS INCLUDED IN THIS TABLE GAVE VARIATIONS FROM A NEGATIVE REACTION; THE 26 COWS NOT INCLUDED GAVE CONSISTENT NEGATIVE TESTS.

front quarters at each examination. In studying the brom-thymol-blue reactions it will be observed that in the infected right rear quarter the reaction tending to shift from a positive to a doubtful reaction and did not seem to be settled at any time. In the case of the infected left front quarter the re-

sults were very inconsistent, characterized by continually changing from positive to negative. On only two occasions did the two non-infected quarters change from a negative to a doubtful reaction.

The variation from a negative reaction of non-infected animals that were present in an infected herd proved rather striking. Such conditions are found in animals C, D, and E in Table II; these were picked at random from a large number of similar cases in two large herds. During the time these cows have been under the writer's observation no streptococci were isolated from their milk and they were furthermore devoid of any indications of mastitis. Definite positive and doubtful reactions were obtained in testing the milk of these cows; such reactions are misleading unless other tests or examinations are made to assist in making a definite diagnosis.

It is these variations of the pH of freshly drawn milk, using brom-thymol-blue indicator, that have caused concern to the veterinarian and milk inspector in detecting cases of mastitis. To insure confidence on the part of the dairyman in the veterinarian and the milk inspector it is necessary that any test used in the diagnosis of mastitis should not give wide unexplainable discrepancies or variations. Such discrepancies in diagnosis, particularly if they affect the economic condition of the dairyman will cause suspicion and immediate lack of coöperation.

According to the early workers the test is based on the fact or supposition that there is an alkaline exudation or transudation of blood or lymph constituents into the milk due to an injury. Specifically in mastitis the positive reaction is attributed to injury caused by the streptococci of mastitis. The interpretation of a positive reaction becomes less definite and more general when it is noted that apparently physiological

conditions cause a positive reaction. Frequently the abnormality of milk due to infection of mastitis can be detected upon physical examination of the milk as early as by the brom-thymol-blue reaction.

SUMMARY

The data presented seem to indicate that:

1. Apparently there are normal physiological factors that are responsible for a variation in the pH of freshly drawn milk.
2. The test cannot be used alone to detect cases of mastitis, since positive reactions were obtained in animals that were always free of mastitis. No definite cause is given for these positive reactions. The work of Hucker *et al.*, was confirmed, indicating that a negative brom-thymol-blue reaction does not assure freedom from mastitis.
3. The brom-thymol-blue reaction is of value as an aid in determining the relative disease or freedom from mastitis of a herd.

If a large number of positive reactions are obtained it is a good indication that something is wrong in the herd but the individual cases cannot be detected.

LETTER FROM GREAT BRITAIN

SOLVING THE SLUM PROBLEM

As ever, housing continues to occupy a great deal of the time and attention of all concerned or interested in health matters in this country. Further legislation in regard to it is in process of finding its way through Parliament into the statute book, and from time to time the Ministry of Health issues circulars and memoranda calling upon or urging local health authorities to take action.

The question of slum clearance, always serious, of late appears to have been taken more seriously. A call for the problem to be tackled vigorously has come from many quarters, many of them of a class in which the slum has been something more than merely a platform subject, with which applause could readily be obtained, and the reputation of being a sociologist of some profundity and an authority on housing easily gained.

Since he took office, Sir E. Hilton Young, the Minister of Health, has earned the reputation of being of those not unwilling, in the political phrase, to explore all avenues to their end, to omit no stone from the process of turning and, in short, to take strong action as and when required. His most recent demonstration of this willingness has been in relation to the slum.

From his department there has come within the last few weeks a manifesto in the shape of a circular addressed to local government bodies as housing authorities, indicating the necessity for abandonment of the *festina lente* policy, and for actually making haste to solve the slum problem. Legal provisions, it is pointed out, are adequate for the purpose, and of this there is no doubt, most governments over a considerable period having taken a hand at legislating in

regard to housing, and seeking to provide local authorities with encouragement, financial and moral, to clear away the property of the slum owner, compensating him on the lowest possible scale, and erecting new and more sanitary buildings on the site.

For years the expenditure on housing has been a terrible strain upon the finances of this country, the amount contributed to housing schemes out of State funds alone between 1919 and 1931 being in the neighborhood of £98,000,000. In spite of this, one of the inducements offered to local authorities to tackle the problem of slum clearance now is that the State contribution is at present on a particularly generous scale! In addition, it is pointed out that at the moment there are other favorable considerations, among them that money is cheap and labor costs low.

Conceivably these temptations may operate to induce the authorities to redouble their efforts to set about preparing a program under which at the end of 5 years the face of the land will no longer be disfigured by slums, and the erstwhile slum dwellers will be living happily and healthily in the new and sanitary accommodation provided for them.

GOOD HOUSES OR GOOD FOOD?

Unfortunately, so far as living happily and healthily is concerned, it appears that there is some possibility of doubt. That there might be a chance that there was a doubt that it might not be for the slum dweller transplanted to improved dwellings all that fancy painted has been suspected for some time by members of the health service and others.

At society meetings and elsewhere it has been mentioned that on new housing estates some of the people seemed not to be flourishing to the extent that had been expected, and that the children were less well nourished, perhaps, than they had been before they left the bad old homes.

To the Medical Officer of Health of Stockton-on-Tees—Dr. G. C. M. M'Gonigle—has fallen the task of showing that the suspicions entertained have been well founded, producing as evidence what has happened in an area and to a section of the population in his own town. Stockton-on-Tees, an important town in the county of Durham, is in normal times a busy manufacturing and shipbuilding center, but has suffered very badly as a result of the depression. Nevertheless, the local authority has endeavored to carry on the usual activities, particularly those concerning public health and housing.

In respect of housing quite considerable expenditure must have been incurred in clearing slums and providing alternative housing, and in 1927 particularly, one "unhealthy area" that was demolished led to the dishousing of some 710 persons. For the accommodation of these citizens a "self-contained municipal housing estate (Mount Pleasant)" was specially built in another part of the town. Watching this group closely, and the mortality and such other figures as were available regarding it, Dr. M'Gonigle found, during the 5 years succeeding its translation from bad to good housing conditions, sufficient evidence of deterioration in the state of health of the constituent members to warrant detailed investigation. This he carried out and, because he was fortunate enough to have a control population almost equal in size and living under conditions identical with those in which the transferred group existed before their removal, the results obtained have a

peculiar value, and the conclusions reached may be regarded as worthy of very real respect.

Briefly, following the closest and most careful examination of all the facts and figures available, and investigation of all the conditions and all the factors that might conceivably be concerned, the conclusion reached was that from the health point of view the transferred group was in a less satisfactory state than the group resident in the bad old slum area; that there had been definite deterioration in the health of the transferred group; and that between the two the only outstanding difference was in regard to diet.

The folks in the slums were called upon to pay less for housing and had more to spend on food; those with the fine houses had to pay for the fineness, and to do so had to go short at meal-times. In a word, they had to kill themselves in order to be able to live in dwellings guaranteed healthy, and the alternatives with which the slum dweller appears to be faced are of remaining in his slum, feeding fat, and taking a chance on its killing him; or moving into a high grade dwelling and living healthily until death from starvation supervenes.

Interesting and important as these observations and conclusions are, it is unlikely that they will affect the views of the government or lead the Minister of Health to order cancellation of the circular to which I have referred and of his instruction to the local housing authorities to prepare and submit to him within 6 months a program of the work in relation to slum clearance that they propose to complete in the ensuing 5 years.

VARIOUS CONFERENCES

Almost daily there arrive programs of conferences to be held during the summer months. Those most recently received include that of the National

Association for the Prevention of Tuberculosis for its nineteenth annual meeting at Cardiff on July 13, 14 and 15, and of the "Sixth English-Speaking Conference on Maternity and Child Welfare." This latter is to be held in London on July 5, 6 and 7.

The main discussion at Cardiff will be on "The Part Played in the Production of Tuberculosis respectively by (1) Infection and (2) Environmental Conditions," and will include references to special investigations carried out in special areas by the National Association, and the Welsh National Memorial Association—the body mainly concerned in dealing with tuberculosis in Wales, and as part of the proceedings there are to be addresses on its history and organization by persons intimately associated with it.

Among speakers announced to take part in the main discussion are Sir Robert Philip, the President of the Conference, to whom the National Association more or less owes its existence; Dr. Nathan Raw, a well known worker in the field of tuberculosis; Dr. W. G. Savage, Medical Officer of Health of Somerset County, Sedgwick Memorial Lecturer in 1932; Dr. Harley Williams, Medical Commissioner of the National Association; and others. Apart from the discussions, arrangements are in hand for visits and demonstrations appropriate to the work of the Conference and the association generally.

The program of the Maternity and Child Welfare Conference appears to be very full with sessions arranged by the various participating organizations on each of the three days. The President on this occasion is Sir George Newman, Chief Medical Officer, Ministry of Health, and he will deliver an

address at the opening session. The subjects to be debated on the first day are "The Scope and Advancement of Ante-Natal Care," and "The Care and Protection of Illegitimate Children in Relation to Their Future Citizenship." The speakers include Miss Lilian Barker, Governor of the Borstal Institution, and Mr. Kirkpatrick of Dr. Barnardo's Homes.

On the evening of the second day, under the Chairmanship of Dr. Eric Pritchard, whose name is well known in connection with child welfare work, there will be a debate on "The Health of the Child in Relation to Its Environment, with Special Reference to Tuberculosis and Overcrowding." On the last day a series of subjects come under discussion, among them "Ways and Means of Propaganda," and "The Diet of the Child after the Period of Milk Feeding." As usual, there will be a child welfare exhibition and a number of social events—among others a garden party at St. James' Palace—and visits to places of importance from the educational point of view.

For the special benefit of medical members also it is noted that a short post-graduate clinical course has been arranged and will be held on July 3 and 4, the two days preceding the opening of the Conference. This and the Tuberculosis Conference usually attract a considerable number of delegates. That numbers may be smaller on this occasion, however, is not improbable on account of the decision of the Minister of Health to sanction the payment of the expenses of only one delegate, instead of those of two, as formerly, out of the funds of local authorities.

CHARLES PORTER, M.D.

London

INDUSTRIAL HYGIENE

Two Studies in the Psychological Effects of Noise—Study No. I, Psychological Experiments on the Effects of Noise, by K. G. Pollock and F. C. Bartlett, considers some preliminary experiments followed by a determination of the effects on simple motor skill and upon mental work. In regard to motor skill, persistent adverse initial effect showed no great magnitude; lack of synchronization tended to be disturbing; initial effects wore off rapidly; adaptation to noise took place rapidly. The initial effects on mental work as well as adaptation were similar to those on motor skill. Discontinuous, loud, mechanical noise was more disturbing than the continuous. A distinction appeared to exist between distraction and irritation. The latter does not necessarily mean less proficient performance. On the whole, all experiments showed that noise tends to produce slight, but readily recoverable, diminutions of efficiency. The effect may be different upon a social group than upon an individual. None of these effects related to auditory performance.

Part II, by H. C. Weston and S. Adams, considers the Effect of Noise on the Performance of Weavers. The results as a whole suggest that noise is detrimental to personal efficiency, though in the present case less than 1 per cent. However, the operations controlled entirely by the weaver occupied not over 5 minutes of the hour. The worker does not become completely adapted or acclimatized to noise even after years of work, but goes through the process of adaptation daily. With the reduction of noise, output becomes consistently more regular and less variable from hour to hour and day to day. While the available data are

insufficient to justify any but tentative conclusions, they suggest that noise is not a negligible factor in industrial efficiency, in non-auditory tasks.—*Report No. 65*, 70 pages, 1932, Medical Research Council, H. M. Stationery Office (procurable from British Library of Information, 270 Madison Ave., New York). E. R. H.

School Health Education—The development of a program of health education in the public schools of the Bellevue-Yorkville District, New York, N. Y., is interestingly described in a well printed booklet of 58 pages. A consultant worked in close coöperation with school and health officials. Officers of the Board of Education and of the Department of Health, district superintendents, principals, teachers, school doctors and nurses, parents, children, staff members, all participated in the project.

After 4 years of experimental work, the summary notes, the teachers in these schools seem to appreciate the opportunities offered by the classroom day for the practice of healthful living and endeavor to help the children use these opportunities to advantage. The school showed an increase in the correction of dental defects averaging from 20 to 30 per cent. Gains in weight were noted, and these opportunities were used to interest the child in growth and to help him to understand what the factors were in his daily living which influenced growth.

A syllabus in health education was used in answering children's questions about the "how and why" of certain desirable behaviors, rather than as subject matter merely to be learned. Despite such obstacles as indifference or

ignorance of parents, poverty, inadequacy of school facilities, ill health on the part of a teacher, lack of sympathy or skill in some teachers, all of the schools are said to give evidence of improvement in individuals and groups in:

Use of the drinking fountains and other school equipment

Cleanliness of buildings and classrooms

Personal cleanliness, choice of lunches

Care of materials

Increased responsibility for ventilation, lighting, and temperature in classrooms

Drinking milk and eating vegetables

Care of younger children in school and at home

Interest in making one's self an efficient member of society

Nina B. Lamkin and Savel Zimand, Education for Healthful Living in the Public Schools of Bellevue-Yorkville, 1927-1931, 1932 (55 cents. postpaid).

Treatment and Prevention of Heat Cramps—The article contains a number of case citations on the administration of common salt to men suffering from heat cramps as well as from prolonged exposure to high temperatures. The author concludes that salt administration has a markedly beneficial effect. Five grams or one teaspoonful to the gallon seems adequate and is not unpleasant to drink.—W. E. Eaton, *U. S. Nav. Med. Bull.*, 31, 2:162-164 (Apr.), 1933.

E. R. H.

Maternity Leave in Denmark—The Danish Women Workers' Union, composed of about 12,000 members, recently adopted a resolution to the effect that the Government and Parliament should be urged to guarantee women workers the payment of their wages in full during a rest period of 6 weeks before and 6 weeks after confinement. At present, women workers in Denmark are entitled to 4 weeks' rest after confinement, together with an

allowance payable from public funds, on presentation of a medical certificate, requiring such a rest period.—*Indust. & Labour Inf.*, XLIV, 6:177 (Nov. 7), 1932. E. R. H.

An Enquiry in Poland—The Polish Ministry of Social Welfare recently appointed a special committee in each district in the country to examine labor conditions in the various occupations with reference to health and safety and to report within 6 months. The committees are composed of the head of the local health service, the factory inspector and the district doctors. When they have submitted their proposals, legislation relating to industrial hygiene and safety will be drafted.—Polish Ministry of Social Welfare, *Indust. & Labour Inf.*, XLVI, 5:123 (May 1), 1933. E. R. H.

State Silicosis Laboratory in Mexico—The Mexican Department of Labour has built a laboratory with microscopic and radiological apparatus for diagnosing silicosis and establishing the resulting incapacity for the purpose of evaluating compensation. The examinations are carried out by the Industrial Hygiene and Safety Section of the Department.—Mexican Department of Labour, *Indust. & Labour Inf.*, XLVI, 6:149 (May 8), 1933. E. R. H.

Annual Report, Bureau of Occupational Diseases, Ohio Department of Health, 1932—This typed report states that the Bureau was established December 31, 1932, to take over the functions of the former Division of Industrial Hygiene which was created in 1913 to make a state survey (reported in a special volume, 1915), and continued after 1915 with a personnel of chief, consultant, and stenographer-clerk. Its salary budget in 1931 was \$6,500, reduced to approximately \$3,250 in 1932, and to \$2,050 for 1933.

Necessarily the personnel has been cut so that at present there is a part-time consultant and part-time stenographer-clerk.

The Bureau receives and evaluates all occupational diseases reported by the physician of the State, examines the records of lead works, determines additional employments from which minors should be prohibited, makes special investigations and performs considerable consulting work as well as the promoting of educational features, but the last two have been greatly curtailed.

During the course of the year, 1,169 reports of occupational diseases were passed upon, of which 1,069 were compensable, 90 were non-compensable, and 10 were acute mishaps, classified under accidents. The gross totals for the preceding four years were 1,189 (1928), 1,412 (1929), 1,334 (1930), and 1,309 (1931). Of these, the non-compensable occupational diseases reported were, respectively, 48, 68, 59, and 77 (acute mishaps not included).

The schedule of compensable diseases in Ohio numbers 22 items, of which "dermatitis" gathers in 70 to 80 per cent of the total cases reported, with lead poisoning next in order (about 15 per cent), tenosynovitis of the wrist tendons also about 15 per cent, and the balance scattered. During the 5-year period, 1928-1932, there were no cases of the following reported: anthrax, glanders, mercury poisoning, phosphorus poisoning, carbon dioxide poisoning, manganese dioxide poisoning, and radium poisoning. None of the following exceeded 11 cases per annum during this period: benzol poisoning (and certain of its derivatives), volatile petroleum products, carbon bisulphide poisoning except 18 cases in an outbreak in 1931, wood alcohol poisoning, epithelioma, brass or zinc poisoning, potassium cyanide poisoning, and sulphur dioxide poisoning. Chrome ulcerations (nasal and skin) ran, for the

5 years: 6, 10, 20, 16, and 79, respectively. Prepatellar bursitis (first reported in 1929) ran 13, 23, 29, and 23, respectively. Compressed air illness ran 16, 62, 59, 5, and 20, respectively.

In the non-compensable group, lung dust afflictions totaled 81 for the 5-year period (anthracosis 1, pneumoconiosis 80); by the year, these were 13, 15, 12, 19, and 22, respectively. Carbon monoxide poisoning, as the result of repeated exposures, ran 2, 2, 2, 4, and 1, respectively; lacquer poisoning (n.o.s.), 3, 3, 1, 2, and 1, respectively. Among afflictions whose causative agent was not clear or definite, bronchitis and asthma registered 11, 14, 12, 10, and 4; neuritis 4, 5, 3, 2, and 3; and tuberculosis 6, 8, 9, 9, and 18.

The majority of the acute mishaps were carbon monoxide poisonings, not including domestic occurrences of the same poisoning.

During the year the consultant was engaged with 121 conferences and 321 correspondence-consultations upon occupational diseases. Some 20 field investigations were made and 16 special inquiries. To render the individual occupational disease reports fairly complete necessitated 817 follow-up form-letters and about 50 special letters of inquiry. A total of 12 days was spent in court and special hearings. The Bureau also prepared an exhibit on occupational diseases and hazards, chiefly silicosis, for the Washington meeting (October 24-27, 1932) of the American Public Health Association.

E. R. H.

Compensation for Occupational Diseases in French West Africa— An order issued by the Governor General of French West Africa on January 22, 1933, provides for the operation in that territory of a French Decree of December 12, 1932, which gave effect to the terms of the Convention concerning workmen's compensation for occu-

pational diseases, adopted by the International Labour Conference at its Seventh Session (1925).—West Africa, *Indust. & Labour Inf.*, XLVI, 4:87 (April 24), 1933. E. R. H.

Safety in the Manufacture and Use of Celluloid—Continuing its series of monographs on industrial safety, the International Labour Office has just published, under the above title, a report on safety in connection with the handling of celluloid.

The monograph was drafted by Mr. Stiller of the German Ministry of Labour.

The report begins with a general survey dealing with the distribution and economic importance of celluloid, the nature and uses of the material, the dangers involved for the workers employed and the neighborhood of undertakings, and the substitutes available. This is followed by a description of technical safety measures, for the protection both of the workers and of the neighborhood, in the manufacture of nitrocellulose, celluloid, celluloid goods, film and film bases, the preparation of cinematographic films, celluloid depots, homework, packing and transport.

The second part of the monograph gives the safety regulations in force in various countries, including Denmark, France, Germany, Great Britain, Italy, Japan, and Sweden.—International Labour Office, *Indust. & Labour Inf.*, XLVI, 6:139-40 (May 8), 1933.

E. R. H.

Medical Certificates and Industrial Diseases—Ever since the Act of 1906 has been in force, the workman suffering from an industrial disease has had to obtain a certificate from the certifying factory surgeon, unless the employer dispenses with it. This system is designed to prevent disputes between employer and the workman by providing for certification by an inde-

pendent doctor with special knowledge of industrial disease, a feature which would not be achieved if certifications by the workman's own medical adviser were substituted. For this, the workman pays a fee of five shillings, but the whole of the compensation is paid by the employer, whereas under the Health Insurance Act weekly contributions are paid by the workers. Home Secretary, Great Britain, *Lancet*, 5720:835 (April 15), 1933.

E. R. H.

The Occupational Progress of Women, 1910-1930—This detailed bulletin should be consulted further by those interested. In brief, during this period, a large increase has taken place among women usually at work and especially women in non-agricultural pursuits. At the same time, a great reduction in child labor has become evident. There has also been a decided change in the distribution of women among the various gainful pursuits. The effects of the industrial depression will be watched with interest.—Mary V. Dempsey, U. S. Women's Bureau, *Bull. No. 104*, 1933, 87 pp.

E. R. H.

Workmen's Compensation in Pulmonary Disease—A description of the various British Acts and Schemes covering compensation for industrial pulmonary diseases, especially silicosis and asbestosis.—Charles L. Sutherland, *J. State Med.*, 40, 12:709-16 (Dec.), 1932. E. R. H.

Health Hazards from Specific Poisons in Industry—Classifying the hazards under five headings—communicable diseases, atmospheric conditions, contact with materials, accidents, and absorption of specific poisons—the author comments upon the company's attitude and that of the workmen in respect to the inspection of the plant and the determination

whether poisonous materials are used. Most of the spectacular and serious occupational cases occur in plants where the workmen and executives alike are ignorant of the poisonous nature of the materials used.

In connection with silica and lead dusts, the author considers that ultra-microscopic size renders control difficult if not impossible in some cases, but points out that a common way to ascertain the presence of invisible dust in a process is to take dust accumulations from rafters, sills, etc. Expensive exhaust systems are of relatively little value if fine dust is permitted to remain on places of lodgment since vibrations and movements of materials continually stir it up. "After some spectacular case of poisoning has occurred, many people would unthinkingly advocate the prohibition of the specific, or all poisonous materials, in industry. This stand, however, seems unreasonable."—F. M. R. Bulmer, *Canad. P. H. J.*, 24, 4:155-61 (April), 1933. E. R. H.

Dust Elimination in the Pottery Industry—There are two generally recognized health hazards in the manufacture of pottery—lead and silica dusts. An experimental study of dust conditions was made in a plant to serve as a guide to remedial measures.

Dust particle count was determined,

using the Greenburg impinger, likewise dust weight determinations. These were made in the jigger shop (clay shop), separate finishing room, stove rooms, and kiln placing rooms.

The average dust count in the clay shop was about 150 particles per c.c., or less than half the strictest requirement of the Public Health Service, and the measures instituted again cut this figure in two. In the finishing room, dust counts of 228 particles and 5.9 mg. per cu. ft., without suction, were reduced to 129 and 1.2 respectively by the use of a new finishing bench with suction. In the kiln placing room the company in question has used kaolin instead of quartz for placing or "bedding" purposes, thus avoiding the flint dust hazard here. (Other interesting dust counts and weights are tabulated.)—Edward Schramm, *J. Am. Ceramic Soc.*, 16, 5:205-13 (May), 1933. E. R. H.

Review of Literature Dealing with Health Hazards in Spray Painting—This special Bulletin No. 15, 44 pages, published in 1930, should be consulted by all interested in this subject and is obtainable from the National Research Council of Canada, Ottawa, price 25 cents. It also contains a valuable bibliography of 148 references. E. R. H.

VITAL STATISTICS

Increase in Heart Disease—Provisional mortality figures for 1932 show that deaths from heart disease in Wisconsin gave a death rate of 218.5 per 100,000 of population, in comparison with a rate of 202.9 for 1931. The rate is said to be the highest ever recorded by the State Health Department. A marked increase in influenza also occurred, 28.6 for 1932 in comparison with 18.7 for 1931. Tuberculosis, on the other hand, showed a decline from 48.7 in 1931 to 45.1 for 1932. The infant mortality rate was estimated provisionally at about 46 per 1,000 live births, as compared with 52.9 in 1931. The death rate from diarrhea and enteritis under 2 years of age was 6.9, the lowest ever reported. Incomplete reports of deaths amounted to 30,046 and of births, about 53,000.—*J. A. M. A.* 100:1350 (Apr. 29), 1933.

Low Records for Contagious Diseases—A survey of five contagious diseases in Rhode Island during the period 1928–1932 revealed that death rates for typhoid fever, diphtheria and scarlet fever were the lowest in the history of the state. The mortality rates for measles and whooping cough also declined in the 5-year period, although both diseases reached record breaking peaks of morbidity in 1932. The survey showed an average of 47 cases with 6 deaths a year for typhoid. Diphtheria declined from 641 cases in 1928 to 260 in 1932, an improvement held to be the result of state-wide immunization. Scarlet fever averaged 1,431 cases, with 14 deaths a year. For measles the average was 4,925 cases a year, with 34 deaths, and for whooping cough it was 592 cases, with 33 deaths. In 1932 there were 11,330 cases of measles and

975 of whooping cough.—*J. A. M. A.* 100:1349 (Apr. 29), 1933.

Diphtheria Mortality in Alabama—Figures just released by the U. S. Public Health Service reveal that the death rate from diphtheria in Alabama for the last year (1932) was the third highest of the 28 states for which provisional figures are available. The diphtheria death rate per 100,000 population in Alabama was 7.5, as compared with 3.8 for all 28 states. West Virginia and Tennessee were the 2 states having higher rates than Alabama, namely, 13.2 and 8.2 per 100,000 population, respectively. The lowest rate was in Montana and Minnesota, the rate being only 0.9 per 100,000 in each of these states.

During the past 3 years, the death rate from diphtheria for the white population of Alabama has increased steadily. In 1930 the rate was 8.7, in 1931 it was 9.0 and in 1932, it was 10.4. For the colored population the rates were 4.2, 5.2, and 2.5 for the 3 years 1930, 1931 and 1932 respectively. The increase, observed for the white population, is counterbalanced to some extent by the decrease for the colored population, so that the 1932 rate for the total population is no higher than the rate in 1931. In 1930 the rate for the total population was only 7.1.

For the 3 years, 1930–1932 the number of immunizations against diphtheria, done almost exclusively in counties with organized health departments, has doubled. There were 142,274 immunizations for this period against 74,543 during the preceding 3-year period. In the last year, the potent one-dose toxoid preparation for diphtheria has eliminated one of the practi-

cal difficulties of mass immunization, since equal or better protection is afforded by this preparation, using only one injection, than was obtained formerly by using three injections.

It must be remembered, however, that to affect the mortality from diphtheria, immunizations must be largely accomplished during the preschool period. Seventy-four per cent of the deaths from diphtheria in Alabama for the years 1930-1932 were among children under 5 years of age. It has been shown that to lower significantly the death rate from diphtheria, 30 per cent of the population of this age group must be immunized. The Census of 1930 gave Alabama 313,882 children between 1 and 5 years of age. Immunization in Alabama so far has reached only a small percentage of this group.

Analysis of diphtheria mortality figures for the counties of Alabama shows wide fluctuations. Three counties show recorded death rates in excess of 30 per 100,000; 4 show rates between 20 and 30; and 9 show rates between 10 and 20. On the other side of the picture, 11 show rates between 3 and 4 per 100,000, 4 between 2 and 3, and 12 counties show no deaths at all from diphtheria in 1932. Obviously, diphtheria presents a serious public health problem in the counties where the mortality is high.—Alabama State Dept. of Health. *Month. Stat. Bull.* (May), 1933, p. 3-4.

Mortality in Certain States During 1932, with Comparative Data for Recent Years—For several years the U. S. Public Health Service has secured, from state health departments, current mortality data and has published death rates from important causes from as many states as could furnish the information. The summary of these preliminary rates serves as a current index of mortality until final figures are available, and for purposes

of comparison, figures derived from the same sources in previous years are used. For the year 1932, nearly all the death rates are based on data from 28 states with an aggregate population of nearly 94 million. While the rates in this group of states may not be the same as those for the total registration area, it is highly probable that the trend in these rates will be comparable with the trend in the rates in the total registration area. In considering the trend of the rates during the last 5 years, it should be remembered that the mortality in 1928 and 1929 was increased somewhat by the influenza epidemic of the winter of 1928-1929, that 1930 was free from any wide-spread epidemic, and that such epidemics as occurred in 1931 and 1932 were distinctly minor.

The death rate from all causes in 27 states reporting was 10.8 in 1932, as compared with 11.0 and 11.2 in 1931 and 1930, respectively. Of the 27 states, 20 showed a decline in 1932 from 1931, and 3 an increase in mortality, with 4 states having the same rates in both years.

In 26 states the infant mortality in 1932 was 58 per 1,000 live births as compared with 61 and 62 for 1931 and 1930, respectively. Considering the individual states, 22 of the 26 states with data available for both years showed a decrease in 1932 as compared with 1931, with increases in the other 4 states.

In spite of the fact that 1932 represents the third year of the depression, the death rate from tuberculosis in the group of 28 states was only 60 per 100,000 as compared to 65 and 68 in 1931 and 1930, respectively. Of the 28 states, 26 showed a decline and only 2 an increase; however, in 4 states the decline was very small.

Typhoid fever continued to decline rather steadily, showing a death rate of 3.2 per 100,000 for 1932 as compared with 3.8 and 4.0 for 1931 and

1930, respectively. Only 5 states had higher typhoid rates in 1932 than in 1931. Diarrhea and enteritis likewise continued a steady decline. The deaths from this cause, of children under 2 years of age, amounted to 10.3 per 100,000 total population as compared with 14.0 and 17.9 in 1931 and 1930, respectively. Of the 27 states with available data, 26 showed decreases and only 1 showed an increase in 1932 over 1931.

Influenza, of apparently a mild form, was rather prevalent in the early spring months of 1932 and again in December, with the major portion of the mild epidemic coming in the last week of 1932 and the first week of 1933. A minor epidemic also occurred in 1931, but 1930 was free from any excess deaths from this cause. The deaths credited to influenza in 1932 amounted to 28 per 100,000 as compared with 26 and 19 in 1931 and 1930, respectively. All of these rates are distinctly lower than those for 1928 and 1929, when a more severe epidemic occurred. Mortality from pneumonia was slightly less in 1932 than in preceding years, being 77 in 1932 as compared with 82 and 83 in 1931 and 1930, respectively. For influenza and pneumonia, combined, the mortality of 105 per 100,000 recorded for 1932 was slightly lower than in 1931 (107) and slightly higher than in 1930 (102). The mortality of 1928 and 1929 was definitely higher for both causes. Of the 28 states, 20 had higher influenza rates in 1932 than in 1931, while only 8 had higher pneumonia rates in 1932.

Because of wave-like fluctuations that occur in the incidence of the communicable diseases of children, the comparison of one year with another means little as far as the real trend of the mortality from these diseases is concerned. Diphtheria, which has been declining for many years, reached a new low level of 3.8 in these 28 states

as compared with 4.0 and 4.6 in 1931 and 1930, respectively. The mortality from this much dreaded disease was lower in 1932 than the mortality from whooping cough.

The death rate from poliomyelitis (0.7) in 1932 was the same as the rate in 1929, and considerably less than in either 1931, when it was 1.9, or in 1930 when it was 1.1. In 1930 the disease was epidemic in certain states, and 1931 marked a considerable epidemic in the eastern states and particularly in New York City. Meningitis mortality was likewise low in 1932, showing only 1.3 deaths per 100,000 population.

The death rate from diabetes was greater in 1932 than in any of the previous 4 years. In 1932 the mortality rate was 21.7 as compared with 20.3 in 1931, 19.1 in 1930, 18.8 in 1929 and 19.4 in 1928. In 21 of the 28 states there was an increase in 1932 as compared with 1931; in 6 states there was a decrease; and in 1 state the same rate prevailed in both years. Cancer continued its steady increase, the rate being 101 per 100,000 in 1932 as against 97.6 in 1931, 96.5 in 1930, 95.5 in 1929 and 95.8 in 1928. In 20 of the 28 states it increased in 1932 as compared with 1931 and in 8 it decreased.

Diseases of the heart also continued to increase, the death rate for 26 states in 1932 being 219.5, as compared with 211.7 in 1931, 209.6 in 1930, 215 in 1929 and 214.6 in 1928, 20 of the 26 states with available data having higher rates in 1932 than in 1931. The death rate from nephritis was about the same in 1932 (84.4) as in 1931 (83.7) but was less than in 1930 (88.0) in the group of 27 states with available data. In 25 states with available data on cerebral hemorrhage, the rate in 1932 was very slightly above that for the last 2 preceding years. In 13 of these states there was an increase in 1932 over 1931, in 11 a decrease, and in 1

the rate was the same for both years.—*Pub. Health Rep.* 48:478-480 (May 5), 1933.

Smallpox in the United States and Canada, 1932—There has been a marked and gratifying decline in the amount of smallpox during the last 3 years. In 1930, the number of cases reported in 44 states, the District of Columbia, and 8 Canadian Provinces totaled 46,654; in 1931, they numbered 29,493; and in 1932, only 13,121. In other words, the incidence of this disease decreased about 37 per cent in 1931, and 56 per cent in 1932; since 1930, there has been a total decline of 72 per cent. No single incident would give American and Canadian public health workers greater satisfaction than to accomplish the final eradication of this unnecessary and preventable disease.

It is significant that over 90 per cent of the 12,784 cases reported in the United States in 1932 occurred in less than half of the 44 states. South Dakota, alone, reported almost 1,800 cases, equivalent to the extremely high case rate of 255 per 100,000 population. If this rate had prevailed throughout the country, there would have occurred 318,000 cases of smallpox in the United States during 1932.

The case of Vermont is unique. In this state, the fourth smallest in the Union in respect to population, there have been reported, during the last 4 years, over 900 cases of smallpox. This is particularly significant in view of the fact that Vermont is surrounded by territory which has been singularly free from this disease for at least a decade. This territory, comprised of the rest of New England, New York, and the Province of Quebec, with nearly 24 million inhabitants, reported only 345 cases of smallpox during 1932. Vermont, on the other hand, with a population of only 361,000, reported 254 cases. In

other words, in Vermont there were 70 cases of smallpox for every 100,000 inhabitants; in the neighboring territory there was only 1 case for every 100,000 persons exposed to the disease. It is significant that Vermont has no compulsory vaccination law on its statute books. It is in this and other states where the routine vaccination of children is neglected that smallpox still lingers to plague public health workers.

The disease as reported throughout the United States and Canada was generally of the mild discrete type, with an average case-fatality rate of about 3 per 1,000 cases. An outstanding exception was recorded in Vancouver, B. C. Here, and in the nearby vicinity, during the early months of 1932, there occurred 56 cases of smallpox, 29 of which were definitely identified as of the confluent, virulent type. Before the outburst was brought under control, 16 persons, after prolonged physical suffering, succumbed to the disease. Only one additional death from smallpox was registered in 8 Canadian provinces last year. Of the total of 56 cases in Vancouver, 39, or 70 per cent, had never been successfully vaccinated prior to infection. The remaining 17 had been vaccinated from 15 to 55 years previously, their immunity having diminished almost to the vanishing point during this long period. No one contracted the disease who had been vaccinated within 15 years. The outbreak was finally brought under complete control through the wholesale vaccination of the population.

This epidemic is most illuminating, for it shows what may happen to a community in which antivaccination propaganda has been rife. One can readily picture conditions in South Dakota, for example, if the same case-fatality rate had prevailed there as was recorded in Vancouver (286 deaths per 1,000 cases). In that event, there would have occurred in the state of South

Dakota, 514 deaths from smallpox during 1932, almost as many deaths as are caused there each year by cancer, and equaling the combined annual

death rate from tuberculosis, appendicitis, and puerperal causes.—*Stat. Bull. Met. Life Ins. Co.* 14:6-7 (May), 1933.

PUBLIC HEALTH ENGINEERING

The Corrosion of Metals by Milk

—In tests carried out in one of the pasteurizing plants of New York City samples of milk were taken from 13 different locations of the pasteurizing equipment and analyzed for copper content. In one of the cases strips of various metals were exposed in raw milk for different lengths of time and at controlled temperatures.

It was demonstrated rather conclusively that copper, nickel, and copper and nickel alloys when exposed to milk during pasteurization may cause an increase above 0.7 p.p.m. or a decrease below 0.3 p.p.m. in the copper content of the milk. This change was more pronounced at the higher temperatures. When milk in contact with nickel loses copper this material is precipitated out and nickel goes into solution. Nickel corroded in milk more readily in the absence of oxygen, while copper corroded more readily in its presence. High chromium nickel iron alloys, "Hyblum" (a high-aluminum nickel-aluminum alloy), chromium-plated copper, and chromium-plated nickel were very resistant to corrosion by milk and for this reason appeared to be satisfactory for dairy equipment. C. G. Fink and F. A. Rohrman, *J. Dairy Sci.*, XV, 9, 73-86 (1932). *Exper. Sta. Record*, U. S. Dept. of Agri. LXVII, 6, 735 (Dec.), 1932. From *Pub. Health Eng. Abstr.*

Jute Causes Trouble—Kalamazoo, Mich., recently completed a new 7,000,000 gal. distribution reservoir and 7,000

ft. of 24" pipe line to connect the old system with the reservoir. Dresser couplings were used on the pipe line, except for the joints to fittings and valves, which were caulked with jute and lead or leadite. Before attempting sterilization all surface dirt was brushed from the inside of the pipe line and reservoir. Then by using a Wallace and Tiernan portable chlorinator the main was chlorinated with a dosage of 40 p.p.m. for 8 hours. The reservoir was then thoroughly sprayed with a solution containing 40 p.p.m. chlorine. Tests for bacteriological examination indicated colon organisms in 0.1 ml. quantities. Sterilization of main and reservoir using a much higher dosage was attempted a second time but bacteriological results were again positive.

An analysis of the jute used in the joints showed positive reactions in samples of 0.05 gm. of the unbraided jute. Three types of aerobic lactose fermenters were recovered from the unbraided jute samples and from the water samples. From the observations the following conclusions seem justified: (1) new installation of water mains and reservoir presented unusual difficulties in sterilization; (2) jute was a major source of contamination of the mains; (3) sterilization of mains contaminated by jute packing is very difficult; (4) bacteriological control is necessary in the proper sterilization of water mains and water equipment. Geo. I. White, W. W. Eng., LXXXV, 24, 1420-21 (Nov. 30), 1932. From *Pub. Health Eng. Abstr.*

Air Conditioning for Small Buildings—In order to supply air conditioning units for small buildings, such as residences, small offices, etc., and still keep the cost of the equipment at a minimum, it has been necessary at the present time to stress cheaper methods of production, distribution and installation of such equipment. At present some attempts are being made to develop cheaper methods of air conditioning but these methods have as yet not been fully developed. The problem of cheaper production methods has been solved by the development of designs which can be produced en masse in units capable of being shipped practically in full assembly. This plan also helps to keep the installation costs at a minimum. As a result of the ability to manufacture standard air conditioning units for small buildings there has been a steady increase in the number of installations of such equipment in the past 12 months. A summary of the various standard units of each type of air conditioning equipment is presented elsewhere in this issue of the Journal along with the principal characteristics of each unit. Some operating data are also included. Anon., *Heat. & Vent.*, XXIX, 29, 10, 23-24 (Oct.), 1932. From *Pub. Health Eng. Abstr.*

Chlorinating an Open Bathing Beach—Lake Lynn, W. Va., is an artificial fresh-water lake formed by a hydro-electric power dam. A section containing about $4\frac{1}{2}$ mil. gal. of water is used as a bathing place by 1,000 to 6,000 persons daily in hot weather. Draw-down of the lake about 4 ft. once a week by the power plant and refilling from the Cheat River gives a complete change of water at the beach every 2-3 weeks. In 1930, 9 out of 16, and in 1931, 5 out of 18 ten c.c. samples showed *B. coli*. About 40 gal. of a solution of HTH powder, containing about 10,000 p.p.m. of available chlor-

ine, was then sprayed on the surface of the water every morning. Gas-forming organisms were not entirely eliminated, but *B. coli* were absent in all samples. Larger chlorine dosage and chlorination of streams entering the lake at the beach are planned. L. M. Board, *Munic. San.*, III, 194, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 5, 156 (May), 1933.

Comparison of Results with Standard Lactose, Brilliant Green Bile, and Dominick-Lauter Broths—The results of experiments on the isolation of *B. coli* in raw, filtered, and chlorinated water using standard lactose broth, brilliant green bile broth (2 per cent bile and 1:75,000 brilliant green) and Dominick-Lauter broth are tabulated and compared. All tubes were incubated for 48 hrs. and positive fermenters examined at the end of 24 and 48 hrs. The presumptive tubes were examined according to standard methods, and also all positive lactose broth and Dominick-Lauter broth tubes were planted direct into brilliant green bile broth, and positive brilliant green bile broth tubes into lactose broth. The total percentage confirmed in lactose broth and brilliant green bile was 28.6 and in Dominick-Lauter 28.3. Of the presumptive lactose broth and Dominick-Lauter tubes planted direct into brilliant green bile broth 86.6 and 99.2 per cent confirmed as against 79.3 and 98.3 per cent, according to standard methods, while of the brilliant green bile presumptives planted direct into lactose broth 97.2 per cent were confirmed, as against 93.7 by standard methods. In raw water brilliant green bile gave 1.4 per cent and Dominick-Lauter broth 0.7 per cent more confirmed results (standard methods) than lactose broth. In filtered water, however, lactose broth gave 37 per cent confirmed while brilliant green bile and Dominick-Lauter each gave 34.6. In

chlorinated water, three 24-hour and twenty-six 48-hour tubes fermented, of which only one or 3.4 per cent confirmed with lactose broth; brilliant green bile and Dominick-Lauter broth each produced one presumptive in 24 hrs. and one in 48 hrs., of which one or 50. per cent confirmed in each medium. The direct planting method takes less time and gives greater recovery of *B. coli* than confirmation by standard methods. The Dominick-Lauter medium showed a very high recovery, occasionally reaching 100 per cent, but is more difficult to prepare than lactose broth or brilliant green bile, and the examination takes longer. N. J. Howard, *J. Am. W. W. Assn.*, 24, 1305, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 5, 161 (May), 1933.

Industrial Wastes Which May or May Not Enter Sewers—In discussing the admission of industrial wastes into sewers, the author divides the wastes into 4 classes: (1) those admissible to sewers without previous treatment; (2) those admissible after flow adjustment; (3) those admissible after preliminary treatment; and (4) those to be excluded. Examples are given of types of wastes belonging to each of these classes and arrangements possible between sewage works and industries are discussed. H. M. Freeburn, *Munic. San.*, 3, 284, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 5 (May), 1933.

Operating Costs of Sewage Treatment in North Carolina—Gastonia, N. C., which treats more than 1 mil. gal. per day of sewage in an activated

sludge plant, using 2.03 cu. ft. of air per gal. of sewage and 7.5 lb. ferric chloride per 1,000 gal. of sludge, and Oliver vacuum filters for sludge dewatering, operates at a cost of \$54.33 per mil. gal. of sewage. High Point, N. C., has a similar plant the operating costs of which are \$42.78 per mil. gal. Two activated sludge plants, located at Charlotte, N. C., which treat over 6 mil. gal. per day, including wastes from dyeing and textile plants, cost \$23 per mil. gal. to operate. Oliver filters are used in one plant for sludge dewatering and the other has separate sludge digestion. *Pub. Works*, 63, 49, 1932; *Sewage Works J.*, 4, 585, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 5 (May), 1933.

Interceptor and Sewage Disposal Works at Fort William, Ont.—An illustrated account of the new sewers and sewage treatment plant installed at Fort William, Ontario, to eliminate the pollution of Neebing River by raw sewage. An intercepting sewer was constructed carrying 3 times the dry weather flow to a disposal plant providing for sedimentation in tanks with double spiral scrapers, sludge digestion, sludge storage during winter and drying on open beds. The plant effluent will be discharged into the lower reaches of the river, the digestion tanks heated to 80° F., the digesting sludge maintained at pH 7.2–7.5, the sludge gas collected and burned and the dried sludge used as fill and fertilizer. R. O. W. Roberts, *Canad. Eng.*, LXIII, 24, 17, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 5, (May), 1933.

FOOD AND NUTRITION

Effects of Freezing on the Spores and Toxin of *Clostridium Botulinum*—The production and marketing of frozen vegetables and fruits without heat sterilization has raised the question as to whether or not there is a possibility of botulinus poisoning arising from the consumption of such products which had been improperly handled. A series of experiments were conducted to study the effect of "quick" and "slow" freezing upon the viability of *Cl. botulinum* spores and the potency of botulinus toxin. Freezing the spores with solid carbon dioxide ice was resorted to for "quick" freezing while exposure in a cold room at a temperature between 18° and 20° F. was used for the "slow" freezing process. In studying the effect of freezing upon *Cl. botulinum* spores the conditions of experimentation resembled those existing in commercial practice. Dried *Cl. botulinum* spores (Type B) suspended and heated in a Sörenson buffer solution of pH 6.9 and in pea juice pH 7.1 were frozen with solid carbon dioxide ice, defrosted at intervals, and the total number of viable spores as well as the presence of toxin determined. There was no reduction in the number of viable spores, neither when defrosted and examined immediately after being frozen nor when they had been frozen for 9 days and then examined. Subcutaneous injections into guinea pigs of portions of centrifugated suspensions after freezing show that no toxin had been liberated by the spores by freezing. A suspension of dried spores of the same botulinus culture was divided among several test tubes and frozen by exposure in a refrigerated room at approximately 20° F. Twenty-four to 36 hours were

required for the suspensions to be thoroughly solidified. Examination of portions one day after being frozen and periodically to 11 weeks showed that there was neither a reduction in the total numbers of living spores, nor was toxin liberated. Botulinus toxin frozen and defrosted 15 times was not reduced in strength.—Lawrence H. James, *J. Infect. Dis.*, 52:236 (Mar.-Apr.), 1933.

The Germicidal Efficiency of Sodium Hydroxide—This work was prompted by the need for an efficient, odorless, and relatively non-poisonous disinfectant sufficiently cheap to warrant its routine use in milk houses, dairy barns, swine barns, and other farm buildings. Preliminary studies on sodium hydroxide indicated a satisfactory germicidal efficiency against non-sporulating organisms. The author has given a comprehensive review of the literature and presents details of his experimental work upon the germicidal efficiency, the effect of the presence of organic matter on germicidal efficiency, the effect of temperature variation, and the factors responsible for destruction of microorganisms by sodium hydroxide. High test commercial lye was found a satisfactory source of sodium hydroxide in addition to being cheap and readily available. The Reddish technic for testing germicidal efficiency was used throughout the experiment, the test organisms being *Brucella abortus* of both bovine and porcine origin and *Escherichia coli*. Tests were also made under field conditions for which a definite technic was worked out. The author concludes that sodium hydroxide in the form of high-test commercial lye appears to satisfy the need for a disinfectant suitable for use in barns and

stables and that it is inexpensive, odorless, and very efficient against *Brucella abortus* and related microorganisms. The velocity of disinfection with sodium hydroxide between 25° C. and 2° C. is independent of temperature changes. This phenomenon appears to be correlated with the peculiar physico-chemical reaction of sodium hydroxide solutions to temperature changes, wherein the ratio of hydroxyl-ion activity to the hydrogen-ion activity increases with a decrease in temperature.

At a given temperature, a given hydroxyl-ion concentration possesses a germicidal activity which is independent of the amount of alkali used to attain the hydroxyl-ion concentration. The author concludes, therefore, that the activity of the hydroxyl-ions is the most important factor in the destruction of microorganisms by sodium hydroxide.—Ernest C. McCulloch, *J. Bact.*, 25:469 (May), 1933.

The Action of Hexylresorcinol on Bacteria in Certain Food Products—The authors have studied the action of hexylresorcinol on bacteria in certain food products with the view that it might be used as an efficient food preservative. The work of previous investigators had shown it to be harmless to man and to possess a high phenol coefficient, properties desirable in a food preservative.

Milk, ground meat, tomatoes, and eggs were chosen as representative foods to be tested with hexylresorcinol. Equal weights of raw test foods were placed in sterile flasks and varying amounts of hexylresorcinol of known concentration added. Six concentrations of hexylresorcinol ranging from 1:100 to 1:10,000, together with control flasks without the added preservative, were employed with each food. The preservative action was checked in each product by making bacterial counts of the controls and of the sam-

ples containing preservative at stated intervals. The results obtained indicate that hexylresorcinol has little preservative action in the protein foods, that is, milk, ground meat, and eggs, only the highest concentration (1:100 dilution) exhibiting any appreciable effect. However, in the acid food tested, tomatoes, hexylresorcinol in dilutions as high as 1:5,000 causes a marked reduction in the bacterial content.—Charles F. Poe and Hazel A. Fehlmann, *J. Bact.*, 25:521 (May), 1933.

Microbiology of Frozen Foods.

IV. Longevity of Certain Pathogenic Bacteria in Frozen Cherries and in Frozen Cherry Juice

—Recognizing that the use of a sewage-polluted water supply or the employment of a typhoid carrier might result in dangerous contamination of foods to be preserved by freezing, experiments were conducted to ascertain the longevity of *Eberthella typhi*, *Salmonella schottmülleri*, *Salmonella aertrycke*, *Bacterium coli* and *Proteus vulgaris* in frozen red sour cherries and frozen cherry juice. Cherries inoculated with the test organisms were packed under 26 in. of vacuum and stored at 0° F. and —40° F. Bacteriological examinations made at regular intervals showed that at 0° F. *B. coli* and *S. aertrycke* survived 12 weeks, *Proteus vulgaris* 14 weeks, *S. schottmülleri* 16 weeks and *E. typhi* 18 weeks. At —40° F. *S. schottmülleri* survived 8 weeks, whereas the remaining four organisms used remained viable for 10 weeks. Sterile cherry juice in ampoules was inoculated with the organism named stored in frozen condition. Several such experiments were conducted. The results of one experiment reported show that *E. typhi* could not be recovered from the frozen juice in the second week, *Proteus vulgaris*, *S. aertrycke*, and *S. schottmülleri* were not viable the third week of storage, and *B. coli* was

not present in viable form the fourth week. The results of these experiments indicate that bacteria of the colontyphoid group might be expected to survive in frozen cherries after two months.—G. I. Wallace and S. E. Park, *J. Infect. Dis.*, 52:146 (Mar.-Apr.), 1933.

Microbiology of Frozen Foods.
V. The Behavior of Clostridium Botulinum in Frozen Fruits and in Vegetables—In view of the fact that no steps are taken to destroy *Cl. botulinum* in the commercial methods of preparation of frozen foods and the possibility of careless handling by consumers unfamiliar with these products, an investigation was undertaken to determine whether or not botulism could occur through the agency of frozen foods. Experiments were conducted to determine the effect of freezing on botulinus toxin as well as on atoxic spores of *Cl. botulinum* in various foods. The foods used were cherries, strawberries, black raspberries, peas, green beans, and carrots. A series of 24 glass containers were packed with each food and subdivisions inoculated with mass cultures of toxic and heat detoxified strains of *Cl. botulinum* types A and B. The containers were stored at -16° C. Samples were examined at intervals of two weeks, two, three, six, nine, and twelve months. Samples were thawed at room temperature. The samples inoculated with toxic cultures were fed only once after thawing. The samples inoculated with atoxic cultures were fed to guinea pigs immediately after thawing, and three, six, and ten days after thawing. It was demonstrated that the toxin and spores of *Cl. botulinum* types A and B were not destroyed after being frozen and held one year at -16° C. Although in many instances toxin production was not demonstrated after thawing at room temperature, anaerobic bacterial growth

was observed in practically all containers held at room temperature. In 4 per cent of the samples fed to guinea pigs after thawing, toxic symptoms did not develop before the fifth day after feeding and usually not until the third week after feeding. It was further observed that potent toxin was present in 4 out of 72 feedings of material taken immediately after thawing from samples originally inoculated with atoxic cultures. In 2 and possibly 3 cases toxin production occurred in such acid fruits as strawberries and black raspberries. Strict anaerobic conditions, however, were not maintained during the time after thawing that feeding tests were made. This may explain why toxin was not found in all cases. It is suggested that toxin might have been liberated during storage as a result of the physical rupture of the spores due to freezing. An experiment was conducted to observe the influence of other organisms on toxin production by *Cl. botulinum*. Types A and B were grown in cherry juice and acidified dextrose broth (pH 4.0) with *L. acidophilus* alone or in combination with this organism and *S. ellipsoideus*. Ninety-six cultures were inoculated, held at room temperature for 5 days and 1 c.c. amounts of culture fed to guinea pigs. Toxin formation was observed in 5 cases: three from dextrose broth inoculated with *Cl. botulinum* A (668) + *S. ellipsoideus*, one from cherry juice, and one from dextrose broth inoculated with *Cl. botulinum* B (437) + *S. ellipsoideus*. *Cl. botulinum* A (637) and Type B (443) did not produce toxin. An experiment was conducted to determine whether freezing would rupture *Cl. botulinum* spores and thereby liberate potent toxin. Washed spore suspensions in sealed sterile ampoules were held at -16° C. and at -79° C. The ampoules were alternately frozen and thawed daily for 4 weeks. Each week 1 c.c. amounts were fed to guinea pigs

to determine the presence of toxin. While in several instances evidence of the presence of toxin was obtained from ampoules held at each temperature, no conclusive proof was obtained that toxin was liberated from the spores of *Cl. botulinum* by freezing. Experiments were conducted to observe whether *Cl. botulinum* could produce toxin in the time elapsing between the canning and the freezing of foods. Non-acid type vegetables and cherries were used for canning and inoculation with detoxified strains of *Cl. botulinum* types A and B. After standing at room temperature for 4, 8, 12, and 24 hours, samples were frozen at -16° C. Bacterial growth was observed after 8 hours. Three days after freezing feedings of 1 c.c. of the material failed to produce symptoms of botulism. Subsequent feedings after longer storage periods gave identical results. It was

concluded from these observations that there is little danger of toxin formation in foods before they are frozen and that frozen foods which are eaten promptly after thawing are probably safe. The point was stressed, however, that some growth of *Cl. botulinum* might occur if foods are not frozen soon after canning. The conclusions were that there is very little danger of botulism from frozen foods that are canned properly and used immediately after defrosting. The spores of *Cl. botulinum* are resistant to freezing and once in frozen food may remain there for long periods of time. If foods containing these spores are allowed to thaw and stand at room temperature for several days before using, they may become very dangerous. This is especially true of frozen vegetables.—G. I. Wallace and S. E. Park, *J. Infect. Dis.*, 52:150 (Mar.-Apr.), 1933.

CHILD HYGIENE

THE EFFECTS OF UNEMPLOYMENT ON CHILDREN AND YOUNG PEOPLE IN GERMANY

RICHARD A. BOLT, M.D., DR.P.H.

Deutsche Institut für Ausländer an der Universität, Berlin, Germany

THE effects of unemployment on children in the United States have been pointed out from time to time in these columns and elsewhere. We now have available the first of a series of inquiries into the effects of unemployment on children in several other countries.¹ In view of the present situation in Germany it is enlightening to review the report on child welfare from that country. It is planned to set forth in following issues of the *Journal* reports of conditions as found in the other countries of Europe.

There are approximately 6 million registered unemployed in Germany today and it is estimated that there are between 1 and 2 million "invisibles," or unemployed who are not registered.

The recovery of the labor market (on which wilfully erroneous information has too frequently been published) has not led to any reemployment of idle hands, but has in many cases tended only to the lengthening of the daily working hours of those still in jobs. . . . In December, 1932, the German National Statistical Office published interesting figures concerning average salaries, and from these we learn that the average wage fixed by collective contract fell, between 1929 and 1932, by 19 to 20 per cent. In 1929, 38 per cent of workers earned more than 36 marks a week; in 1932, the percentage was only 19.9.

On the other hand, the number of workers who earned up to 24 marks a week rose from 45 per cent in 1929 to 60.9 per cent in 1932.

We quote these figures because they show that unemployment, which has become practically permanent in Germany, has brought about a serious lowering of the average standard of living among the population still at work. Moreover the falling off in the consumption of milk, butter, eggs, meat, wheat, flour, and other farm produce, has also aggravated the agricultural crisis.

If we compare the curves of infant mortality in the differing age groups during the past 10 years, with a view to ascertaining the present health conditions of the German child, we arrive at conclusions that do not appear to substantiate the actual degree of economic poverty of large classes of the population, nor the dangers to which the child is exposed. The proper course is to take note of evils when they appear, and before their full effects are apparent in mortality statistics.

In recent years a number of careful scientific studies made among the stricken population showed that, until a short time ago, it was very difficult to prove by accurate statistics that the health of the people in general suffered seriously through unemployment and poverty, but that, nevertheless, no conscientious observer could fail to acknowledge the present needs of individuals or of particular groups. *In times of need, children are always in danger, since any serious fluctuations in the physical, intellectual and moral care they need are a grave obstacle to their normal development.*

With this in view the German Central Union of Private Child Welfare organizations sent out a questionnaire to a considerable number of school physicians, poor law doctors, hospital physicians, family physicians, pediatricians, and directors of municipal Public

1. Welland, Ruth. The Effects of Unemployment on Children and Young People in Germany, in *Children, Young People and Unemployment*, Part I, Germany, pp. 14-53, U. S., Belgium and Switzerland. Published by The Save the Children International Union, 15 Rue Lévrier, Geneva, Switzerland, 1933. The International Save the Children Fund of America, 156 5th Ave., New York. Price 35 cents.

Health Offices requesting carefully considered answers to the following:

1. Have you observed an increase of morbidity among the children of the unemployed, as compared with the children of the families in better conditions?

2. Have you observed an increase in rickets among the children brought for the first time to the child welfare clinics or out-patient departments?

3. Have you observed an increase in illnesses caused by cold, and do you think this is due to inadequate clothing or bad shoes as an effect of the unemployment, and the resulting poverty of the family?

4. Have you observed among the children of the unemployed an increase of illness due to lack of cleanliness?

5. Has reduced living and sleeping accommodation among the unemployed diminished the physical resistance of the children (tiredness, lack of enthusiasm for games, reduced power of concentration, etc.)?

6. Have you observed undernourishment, or bad consequences of irregular and faulty feeding, due to poverty rather than to bad housekeeping?

Answers were received from 29 doctors and 3 municipal health officers in 22 towns and districts. Very suggestive information supplementing the medical reports was received from teachers in kindergartens, day-homes, elementary schools and others dealing with the care of children and young people. Social workers and members of private relief organizations also contributed to the value of this study, as the information in most instances was supplied without solicitation.

At the outset two difficulties were met which were impossible to evaluate when any comparison was attempted between the health conditions of children in working and non-working families. In the first place there exist very few statistics on the physical and health condition of these two classes considered separately, and, in the second place:

... the apparent standard of living in an unemployed family is not necessarily lower than that of a family where the bread-winner

is still at work. Duration of unemployment very largely influences the economic situation of the family.

Unemployment has a direct and indirect effect on child health. The longer it continues, the more children suffer from increasing economic stress. At the outset, the unemployed cut out the greater part, or even the whole, of their expenditure on bodily and intellectual comfort. Very often they move to smaller quarters, a step that in itself has usually a bad effect on the child. No new clothes or underclothing can be bought; and later on the quality, and finally the quantity, of the food is diminished. Careful observations made by physicians in many cases of underfeeding and its fatal consequences show that the unemployed parents have exhausted all possible resources and that acute poverty has set in.

But the children of families still in work are already indirectly, yet gravely, affected by prevailing unemployment. The financial situation of municipal and provincial administrations has, during the last year, become really critical. This is due not only to the large increase in the cost of maintaining the assisted unemployed, but also to the vanishing revenue. On November 1, 1932, 1,849,768 unemployed were supported by the Reich, and 2,046,537 by municipalities and districts. Even were the numbers of the unemployed in Germany to remain stationary, no immediate improvement in the financial situation of the municipalities could be expected, as taxes continue to bring in less and less; some of these taxes produce no revenue whatever, or at best half. In order to guarantee to the assisted unemployed the minimum allocation, in quite a number of municipalities and country districts it was necessary to reduce or cut out entirely all votes for preventive health and child welfare work.

In a study of 43 cities and 44 country districts conducted by the Association of Municipal, School and Poor Law Officers of Health in the spring of 1932 it was found that:

... all of these social-hygienic measures had been reduced. The number of infant and preschool child welfare clinics had decreased, the hours of opening were reduced, and medical assistants were substituted by lay persons. Free distribution of milk, cod liver oil and medicinal foods to especially needy cases has been cut down; in Berlin free milk distribution has been reduced by 50 per cent.

School medical examinations, which used to take place four or five times during the school-life of the child, are now often carried out once or twice only or have been entirely abolished. In the fight against tuberculosis budgets have been sometimes cut by half; milk and disinfectants can often no longer be distributed; in many places admission to sanatoriums is being refused; and the work of dispensaries is seriously compromised. In the post-war years the placing of weakly, convalescent, and sick children in homes and sanatoriums proved one of the best means to improve the children's health. A backward trend can be observed from the statistics of the Verein Landaufenthalt fuer Stadtkinder (Country Holiday Fund), which shows that the number of children sent to recovery homes decreased from 215,656 in the 6 months April 1-September 30, 1930, to 128,652 in the months January 1-November 23, 1932.

Public health work suffers greatly from economic measures. In many cases social workers (Fuersorgerinnen) are still employed, but they have so much to do with inquiries into the economic situation of families applying for relief, that they are quite unable to pursue their proper social and hygienic tasks; another drawback of this new work is that it shakes popular confidence in the social case worker. (The German social worker does preventive health work as well as purely social case work.)

The curtailing of preventive measures has, of course, a serious effect on the health of the people, and especially of the children—the more so as in over 40 of the places mentioned the bad effects of the crisis have already been observed on the health of children. This enforced reduction, together with the increasing poverty of families unemployed for a long time, will undoubtedly in the course of the next months produce a disastrous effect on the German children's health. If, up to now, doctors could still report fairly good conditions among the child population, this can be attributed to the valuable and efficient public health system that has operated until recently, and also to the fact that the unemployed families have made use of all their resources.

It should be noted that even at the present time (May, 1933) a number of the leading pediatricists in the large cities such as Berlin, Hamburg, and Dresden maintain that the health of the infants and very young children remains good and that even the school children do not seem to be suffering

unduly. They point out, however, that the children between 3 years and school age are showing the greatest strain, both physically and mentally.

In the actual state of affairs, one of the most important assets in Germany, besides the family reserves mentioned above, is the present system of well organized public health work, with an efficient medical service dealing with the care, feeding and education of the infant, the preschool child, and school child. Proof of the real or apparent private reserves, either exhausted or still available, may be seen in the very slow decline of the general health standard. The value of small allotments, where vegetables, fruit, and potatoes can be grown, is considerable. These advantages compensate the winter discomforts of the small huts built in these allotments: space restrictions, bad lighting, inadequate heating, etc. During many months in the year they give the children the possibility of living and playing in the open. Many city families have developed contacts with country relatives and friends. Private organizations and neighbors help now and then. Any belongings of value are pawned. *The most important reserve, however—and the complete consumption of which is vitally serious—is the mother's physical and moral stamina.*

From medical reports we gather that, until recently, no lowering of health standards could be observed among children, contrary to observations made during the war, when the consequences of immediate lack of food were speedily evident. But today nearly all doctors agree that the normal rise in the standard of child health has come to a dead stop, or has fallen.

According to a Memorandum on health conditions of children in Prussian elementary schools (Preussisches Ministerium fuer Volkswohlfahrt, 1932) a falling off in the nutrition of children has been observed only since the autumn of 1931. . . . Many school teachers, kindergarten teachers and social workers call attention to the growing hunger of the children and all its consequences. . . . Professor Gastpar reports that the upward trend in child health in Stuttgart has come to a dead stop, that there is a marked fall in the nutrition of new pupils, and that active tuberculosis has much increased among school children since 1928.

German medical experts have not yet arrived at a unity of views on the unfavorable influence of parental unemployment on the health of the child. The ill effects of unemployment do not appear everywhere with the

same rapidity, because family resources vary largely (garden plots; relations in the country; remunerative employment of the mother; clandestine work), and also because the length of unemployment is an important factor. The proof that ill effects have greatly increased during the past 2 years can be found in the answer given to the *Deutsche Zentrale* by a large number of doctors who have experience among the unemployed. Contrary to the medical inquiry, the one made among a very large number of teachers of all denominations and political views, kindergarten teachers, heads of day-homes, social workers, and leaders of child welfare organizations, has stressed the fact that educational conditions are far more serious in the unemployed than in the working family.

All age groups, save the infant, are affected; and even the baby can suffer from nervousness and lack of mental balance in its surroundings. Among children of preschool and school age, the damage caused is already so

obvious that the united efforts of all public and private child welfare organizations are needed to ward off further and serious evil from the young generation. In many cases it is already impossible to repair the damage done. We must here take very serious exception to the view that the effects of poverty are identical in all families, whether they are unemployed, or working for insufficient wages that are scarcely better than the dole. Even when resources are reduced in both cases to a pittance, the rhythm of life is entirely different in a family whose members are idle. In an article published in the *German Red Cross Review* (*Wirtschaftsnot und Volksgesundheit. Blätter des Deutschen Roten Kreuzes*, Berlin, December, 1932), Professor Fritz Rott states that the mental balance of the unemployed is seriously disturbed. "Increased neurosis is perhaps the most serious danger to health caused by the present crisis. This increase is not sufficiently taken into account, because it is not easily recognized."

PUBLIC HEALTH NURSING*

Visiting Nurses and Communicable Disease—Back in 1923 Haven Emerson, M.D., of New York, said:

It would appear that many cities do not advise concurrent disinfection in either the major or minor communicable diseases, whereas instruction in the need and in the simple household technique of this procedure is well nigh universal wherever visiting nurses in public or private employ are permitted to give bedside care. Without concurrent disinfection little of real value to the members of the household follows from the procedures of isolation and quarantine. This is the one essential and elementary precaution in every sick room where there is a case of communicable disease. In the interest of the patient, the attendant, the other persons in the family or household, concurrent disinfection is of infinitely more value than terminal disinfection or the mere separation of the sick person in a room apart. Concurrent disinfection of discharges throughout

the period of communicability of the disease is the chief object of isolation. Where it is neither taught nor practiced, isolation is profitless.

The Superintendent of Nursing of the Metropolitan Life Insurance Company reported in this magazine this spring that in 1931 her company had expended more than \$4,000,000 for home nursing service to more than 800,000 of its own policyholders. In a close analysis of 200,000 of these it was found that only 5 per cent of the visits were made to patients suffering with measles, scarlet fever, whooping cough, diphtheria, and other communicable diseases, showing that visiting nurses are not doing this work to any extent. Is it because health commissioners do not see the possibilities or because they do not take advantage of them when they do see them?

Now comes the report of a survey of the *Communicable Disease Hospital*

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

needs of the Borough of the Bronx, City of New York. The Henry Street Visiting Nurse Service has included the care of acute communicable disease on its program for 15 years. Of the 9,366 communicable disease cases cared for from 1927 to 1931, inclusive, measles constituted 52 per cent; diphtheria, 9 per cent; scarlet fever, 21 per cent; and whooping cough, 18 per cent.

The cost of the Henry Street Visiting Nurse Service is \$1.15 per visit and the average number of visits in 1931 was 6.2 visits per case, representing an average cost of \$7.13 per patient. At the Willard Parker Hospital, where most of the Bronx communicable disease cases go, the average cost of hospital care of each case of diphtheria in 1930 was \$171; scarlet fever, \$234; measles, \$85; and whooping cough, \$194.

The survey states: "The low mortality among the patients under private medical care using the nursing service bears eloquent testimony to the favorable results of a high quality of visiting nursing in the care of contagion. The ratio of deaths to cases is extremely low."

Every Public Health Nurse Should Have a Set—A new set of five sex education pamphlets written by Dr. Thurman B. Rice replaces an older series published by the American Medical Association. The set consists of: The Story of Life (For boys and girls 10 years of age); In Training (For boys of high school age); How Life Goes On (For girls of high school age); The Age of Romance (For young men

and women); The Venereal Diseases (For both sexes, high school age or older).

Dr. Rice holds to the fundamental principle that civilization is founded on the home, yet he faces the fact that when young people come to learning about the processes of procreation they will no longer be satisfied with sophistry. He has taken the position that there can be no ignoring or isolating sex because it is so deeply interwoven with the mental, moral, and spiritual as well as the physical life.

The pamphlets reflect Dr. Rice's belief that no man or woman can understand his or her own sexual life and problems without understanding those of the other sex as well. He writes about sex for little children of both sexes in one pamphlet and uses the same methods in speaking to adults. He addresses high school boys and girls separately but teaches the same fundamental lessons to both groups and gives each a glimpse of physiology and psychology of the other sex. Yet he gives no descriptions or diagrams of sex organs; only such references to physiology as are needed for the discussion.

"The pamphlets are not medical treatises but intensely human and practical documents which display a real grasp of the needs in this field of health education."

Parents should use the pamphlets as a supplement to the confidential personal teaching necessary to transmit knowledge of sex to their children. They should read them first then turn them over to their children according to age. Teachers will find them useful for their own information and for the occasional instances when they have to function because the home has failed to do so. Doctors will find the set useful to recommend to parents.

The pamphlets are attractively printed and illustrated. The price is \$1.00 for the set of five or 25¢ for each

pamphlet.—Sex Education Pamphlets, review by W. W. Bauer, M.D., Am. Med. Assn., *Hygeia*, XI, 6:561 (June), 1933.

Nurses Save Taxpayers—How to save the taxpayers of the state, and at the same time give adequate relief to those in need—that is a problem which has taxed the ingenuity of both local and state relief officials.

Medical and nursing care for relief clients who are sick at home are classed as necessities of life, along with food, shelter and clothing, under the emergency relief act passed in New York State in 1931.

In many communities in the State, large sums of money have been expended to provide hospital care for relief clients who were unable to get adequate nursing care in their homes. In 1931 and 1932, some communities spent more of public funds for hospital care than they spent for all items of home relief—food, fuel, clothing, etc.

Both urban and rural physicians have cited instances in which, for the sake of safety, patients, not critically ill, have been sent to the hospital for a week or more at a time, simply because competent bedside nursing service was not available to the patients in their homes. The cost of a week in a hospital ranges from \$17.50 to \$38.50, with the average well over \$20 per week. In the few communities where visiting nursing service was available, a patient who would otherwise be sent to the hospital, was given competent care in the home for a fraction of the institutional cost.

The great need for nursing as well as medical care in the homes of the unemployed was strikingly shown in a sickness census made last December by the State Department of Health at the request of the State Temporary Emergency Relief Administration. It was found that while sicknesses were not much more numerous among the

families of the unemployed, they were, however, more prolonged. More than 40 per cent of those disabled by illness on the day of the census had been ill for more than a year. Among those who had been ill for less than a year, the average illness lasted more than three weeks.

On the basis of this report of sickness and a study of unemployment among qualified graduate nurses in the State, the Temporary Emergency Relief Administration made an allotment of funds to the State Department of Health, to inaugurate, under its supervision, a statewide system of bedside nursing for relief clients sick in their homes.

Since the middle of February almost 200 nurses have been employed at a weekly work relief wage of \$17.50 per week to give home bedside nursing to relief clients in more than half of the welfare districts of New York State. The allotments were based on the community needs for bedside nursing, the availability of qualified nurses in need of work, and the assurance that competent nursing supervision could be given locally.

This project, therefore, has been one of "double relief," both for the nurses and the sick.

The devoted work of these nurses has been revealed in numerous letters from patients, welfare officials, and nursing agencies. In one family, the parents of a sick child wrote that they felt the expert care given by the work relief nurse had saved the life of the child. In an upstate city, both state and local health authorities felt that the aid given by these nurses was invaluable in controlling a serious epidemic.

In several cities these nurses have aided the welfare officials in making sure that all the young children in needy families get fresh milk, cod liver oil and other protective foods so necessary to insure normal growth and devel-

opment, and to prevent the crippling effects of malnutrition and under-nourishment.

These nurses have been very active in the statewide campaign to protect each and every young child from the ravages of that age-old enemy of childhood, diphtheria. Has your child been protected by having 2 doses of toxoid or 3 doses of toxin-antitoxin? The treatments are both safe and painless.

These nurses do save taxpayers. They save money by reducing hospital

expense and lengthy periods of medical care. They save future misery and illness by giving health instruction to parents in their homes. They save lives by aiding in the protection of children against diphtheria and malnutrition, *and*, they insure ample dividends in the increased health and happiness of a great many citizens of this State.—H. Jackson Davis, Nurses Save Taxpayers, *News Service*, New York State Dept. of Health, Radio Talk No. 594, Tuesday, May 16, 1933.

EDUCATION AND PUBLICITY*

What to Say About Low Death Rates in the Depression—An outstanding problem in public health publicity and interpretation just now seems to be to get public opinion back of reasonably high standards of public health work in face of the generally low death rates which seem to make retrenchment much more safe than it really is. Dr. W. W. Bauer has contributed an excellent article on this subject called "The Death-Rate in the Depression," American Mercury, May, 1933, the whole of which all health workers will wish to read. He answers a frequently expressed defense of depressions with force:

The thought has also been advanced that enforced retrenchment in matters of food, in burning the candle at both ends through high-pressure business and hectic social activity, and in dissipation, will be effective in improving the health of the American people. Perhaps a few gourmands may be prevented from digging their graves with their teeth quite as fast as they might like to do; possibly a number of foolish debutantes are restrained from dancing themselves into a tuberculosis sanatorium or an early grave; conceivably business men now have less occasion to drive themselves to physical bankruptcy for the sake of piling up profits. But must we have a Depression that threatens the integrity of the whole world for these infinitesimal gains, doubtful benefits at the very best? Such arguments are the acme of futility.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Another magazine article on the general question of stabilizing health department income is "Defending Health Budgets" by Paul O. Komora, Hospital Social Service, May, 1933. It can be had in reprint form from National Committee for Mental Hygiene, 450 Seventh Ave., New York City.

National Award to Birmingham's Health Department — *Birmingham's Health*, the bulletin of the Birmingham, Alabama, Health Department received one of five awards given this year by the Social Work Publicity Council. This was the only award in the public health field, the other citations going to the Survey Graphic; the Cincinnati Community Chest for its Women's Crusade; Chicago Council of Social Agencies for its News Letter; and the Welfare Council of New York for its newspaper publicity interpreting a study of boys' recreation needs in Brooklyn.

The citation to Birmingham reads:

It takes courage on the part of a health officer to speak out as openly about health dangers as about accomplishments because most communities are ostrich-like, squeamish about the possibility of injuring civic reputation. It is the quality of the frankness which shines from the pages of *Birmingham's Health*, the bulletin of the Birmingham, Alabama, Health Department, that wins admiration. The bulletin has been plain-spoken especially during the last twelve months about the dangers courted in cutting appropriations for health work, putting its messages on a wholesomely constructive basis. "Disease dies

He is the best leader who most fully understands the nature of things, so that his plans are not doomed to ultimate failure; who possesses an active, far-ranging imagination which can see many possibilities; who has a sense of values, so that among possibilities he is able to choose the most excellent; who has a sense of order, to give form, design and program to the values and purposes he selects; who has practical sense and judgment, and so uses the most feasible means to accomplish his ends; and who has the energy and enthusiasm to carry his plans persistently toward fruition.—*Antioch Notes*

down only when fought; and fought with time, energy, and money. Clean milk can be obtained only by paying for inspectors, veterinarians and laboratory technicians. Mosquitoes cannot be eliminated with propaganda and ballyhoo, but only with oil, drainage and hard labor."

Another of its commendable franknesses is in this matter of the current favorable health figures and the over-confidence this may bring. "We must not deceive ourselves. . . . If present day conditions . . . continue, we shall encounter a desperate tomorrow. With all the mobilized forces of science in a nation at war, the want and distress of 1914-1918 is reflected still in the health of the children of Central Europe born during these years. With less than the very best of modern science as expressed in preventive medicine and public health from the want of 1929-1933 will come a depression in health and strength and life which will last half a century."

This courageous health information is attractively presented. The bulletin has the feel of a friendly visitor who would be welcome in any household. The articles are brief; the subject matter pertinent and well selected. The style is straightforward, inspiring confidence, and while impersonal, it seems to speak directly to the individual reader. Yet it does not make a strained attempt to "personalize" the printed word.

The arrangement of the material is good. On the front page is a picture or graph. The inside cover page is a directory of the department personnel, stating plainly the room number and telephone extension, and on the back page current statistical facts. The typography and layout contribute much to make this bulletin noteworthy. Large, readable type and plenty of lead and margin space lure the reader on. Before he knows it he has read the entire bulletin. The use of modernized Roman for the headings gives it an up-to-date and fresh appearance.

Some of the cover pages are striking. The issue of April, 1932, makes excellent use of a graph in three dimensions. Clever and timely is the jigsaw design of the April, 1933, number, visualizing for the lay reader how little of the medical dollar is spent for public health.

Our congratulations to Dr. J. D. Dowling, and K. W. Grimley, bulletin editor.

Reconstruction As of 1934—Key-note—Each year the National Tuberculosis Association and its affiliated as-

sociations emphasize one aspect of tuberculosis control. This has come to be known as the Early Diagnosis Campaign. Reconstruction of public health will be the central theme in 1934.

Disaster has been averted by shoring up banking, industry, farming, and other institutions mercilessly shaken by the depression. It is time to reconstruct. Public health, never a sturdy enough structure, has suffered violent shocks. Patchwork will not do. Rebuilding on the solid foundation of modern medical knowledge is the best course. It will be the purpose of the campaign to show that by modern methods health can be secured. While tuberculosis organizations will emphasize the need of providing tuberculosis control facilities, it is hoped that all health agencies will participate in sounding the reconstruction note.

H. E. K.

The Second Health Education Institute—Dr. Iago Galdston will again direct the Health Education Institute, the second to be conducted by the Health Education Section. The dates are October 7 to 9, 1933, immediately preceding the American Public Health Association meeting at Indianapolis.

The theme proposed for this year's Institute is "The Psychology of Health Education." Three lectures will bring out principles of group education including motivation; application of psychological principles to definite health education instruments with examples and critical examination and analysis of existing health education materials.

In two round table sessions definitely assigned projects in health education will be discussed.

It is proposed to limit the student body to 60, with the whole group listening as a unit to the three lectures, and separating for round tables according to some convenient classification.

The "Jig-Saw" Simplified—Under another heading in this issue we are reminded of difficulties in deciding "what to tell the public."

An assortment of short articles believed to present what is true, insofar as we know what is true in the early months of 1933, comes in "What to Tell the Public About Health," recently issued by the American Public Health Association, 450 7th Ave., New York.

This collection of about 200 short articles is reprinted from the later issues of *Public Health News*, the monthly syndicated bulletin edited for the A.P.H.A. by John Hall.

The articles may be used as is. Paragraphs and sections may be copied. Any of the material may be re-written in the particular style of the individual health educator. The "Foreword" by Ira V. Hiscock points out some use possibilities.

A section on "Organizations That Supply Health Education Material" should prove useful. Discrimination will need to be exercised in making selections from the educational offerings of manufacturers included in this directory. The 9-point classification offered by T. J. Edmonds should be applied to what we accept from the business world for distribution.

"The Jig-Saw Puzzle of Health Publicity"—Under this title T. J. Edmonds has discussed in a conference paper an experiment he has made in checking newspapers and magazines for evidences of interest in the subject of health.

Here is what he discovered:

In the issue of *Liberty* of April 22, 1933, there were 24 advertisements. Twenty of these contained a health motive. Following are a few of the catch phrases:

Mouth happiness.

Squibb minded.

No time to neglect health. Be safe and fight colds.

Antiseptic kills germs even when it is diluted.

So easy on the hands.

Hair today and gone tomorrow.

Tones and strengthens your intestines.

Rich in vitamins B, C, D. The kind doctors advise.

Women call these wonderful tablets the internal cosmetic. They remove the inside cause of blemishes, pimples, headaches and that general run down feeling.

Brighten the eyes and clear up blood-shot condition.

One drop stops pain instantly.

Stop dandruff the pleasant way.

Corrects eczema, ringworm, pimples and rash.

Happy legs are here again.

Tums for the tummy.

Next I tore a page at random out of the Sunday issue of a metropolitan daily. It contained beside reading matter five display advertisements. The subject matter was as follows: "Bright woman lost 20 pounds"; Find why your feet hurt; The girl who had never been kissed, title; reading matter beginning "If you think yellow unsightly teeth are natural : . ."; The dread body odor no longer; The new Saxon-weave suit. Four out of five on the health motive.

This and other instances demonstrate interest in health but Mr. Edmonds finds little discrimination shown in the sources from which material is taken and its soundness. He classifies the published material under nine groupings as:

1. The knowingly false
2. Deliberately distorted
3. Wilfully exaggerated
4. Carelessly misrepresented
5. Hastily generalized
6. Honestly misinterpreted
7. Insufficiently checked
8. Incompletely proven
9. Scientifically established

Commenting on these groupings, Mr. Edmonds says that No. 1 can be safely left to the American Medical Association; groups No. 2 to No. 5 are:

an enormous and powerful assemblage, backed by money, organization and respectability. In the field of health publicity more than in any other, the public has been the victim of misleading publicity—some of it sincerely

mistaken—some of it carelessly regardless of the necessity of proof—some of it deliberately synthetic. . . .

Some catch-words that proclaim a pernicious philosophy have become popular—partly because they expressed an honest misconception that was popular. Such was "Don't sell America short," and such is, "Buy American." . . .

The same philosophy applies to catch-words in the health field. Some brevities are true or almost true—but it is the rare one that is righteous—it is an almost impossible task for the advertising artist to produce a sententious generalization that tabloids a truth in terse and striking terms.

Moses did it in the ten commandments. Christ did it in the beatitudes. Both of these sets of eternal brevities were composed on a mountain top. And occasionally some seller of good goods, some propagandist of a great idea, some missionary of a righteous cause, climbs up the arduous mountain slope of fact to the peak of inspiration and utters truth in words simple and few.

In groups No. 6, No. 7, and No. 8 Mr. Edmonds finds that social workers and health educators have been guilty and he cites some of the fallacies in our health slogans.

. . . Health workers often honestly draw misleading inferences from statistical trends. The trouble is that they do not use a control group. Here is an interesting instance of a correct conclusion reached by illogical methods. We have tried to demonstrate the adage, "Public Health work pays," by citing decreases in rates after certain work was begun. That didn't prove it. A parallel is not proof, and it is a common error to confuse sequence with causation. But the same conclusion has been proved by correct scientific methods. . . .

Many of us, I confess, have been guilty of trying to alarm the public about the increase in the heart disease death rate. Our motive was good—that heart disease in many respects is similar to tuberculosis and that it will to a limited degree respond similarly to a public health program aimed at reduction. And by such methods it has already been reduced in some states.

But our ballyhoo is vulnerable in several respects—and in our enthusiasm we have overbid our hand. In the first place heart disease is an embracing term. It includes a lot of separate forms of disease—all of the circulatory system, it is true. . . .

If all the ailments of the respiratory system were grouped together in vital statistics that disease, whatever it might be called, would be the leading cause of death instead of heart disease. . . .

So statistics are like mattresses—it always pays to slit them open to see what they are made of. Statistics are true only if properly interpreted, interesting only if humanized and valuable only if rightly used.

Now that we have discarded so many of the pieces of our puzzle you ask naturally if there is anything left out of which we can fit a publicity picture. Are we safe in saying anything?

One good rule is to play the game with the medical profession. If we make propaganda out of facts endorsed by scientific medicine, we will either be right or wrong in mighty respectable company. If we do not travel too far ahead of public knowledge—just a little in advance in the right direction—we are about as safe as one can expect to be in this changing world.

There seems to be a zone of white light wherein dwell facts that are well demonstrated and accepted by majority opinion. Few people now question the efficacy of immunization against smallpox and diphtheria. Few deny that safe water and safe milk have something to do with typhoid. No one will dispute the advisability of maintaining general bodily resistance. Whatever may be said about pasteurization and tuberculin testing I have heard no attack on mother's milk. Variety in foods producing something like a balanced diet appeals to our gustatory sense as well as our aversion to monotony. Brushing the teeth is defensible on esthetic grounds at least. Exercise brings its own easily recognizable reward, and loss of sleep its own punishment. Whether wet or dry politically we prefer that the man driving down the road toward us shall not have mixed too much alcohol with his gasoline. Although not frightened by the B.O. advertising we will at least agree that an occasional bath counteracts to some degree that peculiarly offensive racial aroma of the Caucasian. I never saw a vitamin, but I know that orange juice and prunes ultimately and indirectly improve one's disposition. And I wouldn't be without a first aid kit, a thermometer and a box of kleenex or its substitute either in a home or school.

And there's one slogan that I believe is a safe generalization: "The early diagnosis may catch the germ." There may be more.

So there are plenty of things we can say--

safely. Let's say them over and over in new ways. And the doubtful things we might discuss, saying "So-and-so says," or insuring ourselves against embarrassment by that convenient newspaper joker, "It is alleged."

Nutrition Demonstrations for Relief Workers—A series of nutrition demonstrations designed to instruct social workers and nurses how to advise families faced with the problem of selection and preparation of food with minimum expenditure was recently organized under the auspices of the Newark Welfare Federation.

The coöperating agencies included the nutrition department of the public schools and the Essex County Tuberculosis League.

The assistance of the Director of Home Economics for the Public Service Corporation and the Home Demonstration Agent of the State Department of Agriculture was obtained by the Committee. The Public Service Corporation donated the use of its centrally located demonstration kitchen and a part of the food used. Flour was given by the Red Cross and the remaining expenses paid by the Welfare Federation. Newspaper publicity was arranged by the Essex County Tuberculosis League.

The program was designed to cover foods essential to health under emergency conditions and protective foods as well as economies in fuel, labor and equipment.

New Popular Movies on Milk and Diphtheria—Two new motion picture films, one on milk and the other on diphtheria, have been added to the loan library of the State Department of Public Health. They are available on 16mm stock only. The diphtheria picture is one reel in length, requiring about 15 minutes for screening. The milk picture is two reels in length and requires half an hour for screening. Both were made by the State Department of Public Health and relate al-

together to Illinois conditions. The photography was done by Dr. A. C. Baxter, assistant director of the Department.

The picture on diphtheria shows step by step how the medical profession and the health officials come into action when a case of diphtheria develops. Each essential procedure in the management of a case of diphtheria, from the moment when a physician is called by the family to the termination of quarantine, is brought out. This, of course, includes the taking of specimens for laboratory examination, treatment with antitoxin, quarantine, protection of contacts, etc. The importance of toxoid in protecting children is also emphasized as a feature of the picture.

The picture on milk relates to both production and distribution. All of the scenes are of farms, dairies and pasteurizing plants in Illinois. Every important step in the production and distribution of milk is shown with particular emphasis upon those processes, such as pasteurization, laboratory testing and bottling, which protect the consumer from unsafe or contaminated milk.

These pictures are available on loan without local cost in Illinois.—B. K. Richardson.

New Movie for Medical Audiences—A new motion picture film on approved methods and technic of taking and mailing specimens for diagnostic laboratory examination has recently been completed by the State Department of Public Health and is now available on 16mm stock only. Two features of the picture deal with taking specimens for the diagnosis of whooping cough by the cough plate method and of taking specimens that may be mailed for dark field examination. Other parts of the film show the technic of taking and the appropriate way to prepare for mailing blood, sputum and

other specimens for tests relating to syphilis, tuberculosis, typhoid fever, gonorrhea, malaria, diphtheria, etc.

A lecturer from the Department is available to discuss subjects covered in the picture. This motion picture film was made especially for the medical profession. It is available for the use of medical societies in Illinois without cost.—B. K. Richardson.

Where East and West Meet—
From where this is written Honolulu seems to be near the end of the world—with a new world just beyond to the west.

But the Child Health Day edition of *Honolulu Star-Bulletin* looks like a special edition from any good sized home town. Advertisements and illustrations maintain the illusion of a nearby community. Articles by Health Department and Education Department officials and others complete the picture. One good story tells how a physician-father built up a backyard playground and garden for a young son. Philip S. Platt tells about Palama Settlement health work, and James G. Stone, Tuberculosis Committee and other health education activities, assembled the edition.

BOOKS RECEIVED

THE VITAMINS IN HEALTH AND DISEASE. By Barnett Sure. Baltimore: Williams and Wilkins, 1933. 206 pp. Price, \$2.00.

GASTRIC ANACIDITY: ITS RELATION TO DISEASE. By Arthur L. Bloomfield and W. Scott Polland. New York: Macmillan, 1933. 183 pp. Price, \$2.50.

THE CLINICAL ASPECT OF CHRONIC POISONING BY ALUMINUM AND ITS ALLOYS. By Lep Spira. London: John Bale, Sons & Danielsson, 1933. 28 pp. Price, \$.75.

EPIDEMIOLOGY IN RELATION TO AIR TRAVEL. By Arthur Massey. London: Lewis & Co., 1933. 59 pp. Price, \$2.00.

THE DYNAMICS OF THERAPY IN A CONTROLLED RELATIONSHIP. By Jessie Taft. New York: Macmillan, 1933. 296 pp. Price, \$2.50.

DIET IN SINUS INFECTIONS AND COLDS. By Egon V. Ullmann. New York: Macmillan, 1933. 166 pp. Price, \$2.00.

NOTES ON VITAMINS AND DIETS. Daniel Thomas Quigley. Chicago: Consolidated Book Publishers, 1933. 128 pp. Price, \$1.00.

SEX EDUCATION PAMPHLETS. THE STORY OF LIFE, IN TRAINING, HOW LIFE GOES ON, THE AGE OF ROMANCE, THE VENEREAL DISEASES. By Thurman B. Rice. Chicago: American Medical Association, 1933. \$.25 each, Set \$1.00.

IOWA WHITE HOUSE CONFERENCE ON CHILD HEALTH AND PROTECTION. April 14 and 15, 1932. Des Moines: Iowa Pupils Reading Circle, 1932. 506 pp. Price, \$1.95.

BOOKS AND REPORTS

Directory of Psychiatric Clinics in the United States—*Compiled and edited by the Division on Community Clinics of The National Committee for Mental Hygiene. New York: The Commonwealth Fund, 1932.* 165 pp. Price, \$1.00.

This is the third edition of a very useful reference book for all those interested in the development of psychiatric services for children, neurological clinics, and mental hygiene societies. For convenient reference the material is arranged alphabetically by states and localities within each state. "No attempt is made to evaluate the service of the clinics, but the Directory does indicate the type of organization and the scope of the work in each case." Private clinics do not come within the purview of this survey.

Of the 674 clinics listed in the Directory, 232 have staffs made up of a psychiatrist, psychologist, and psychiatric social workers. About 50 clinics serve adults exclusively. Since the 1928 Directory was published, there has been a net increase of 130 clinics for children.

The first section of the Directory outlines the mental hygiene activities of the federal government, including a list of the neuropsychiatric hospitals operated by the Veterans' Bureau and naming the officers in charge.

The foreward states that "a further service relative to the work of clinics may also be mentioned. The generally recognized desirability of comparable records and statistics led to an effort in this direction by the staffs of the clinics operating under the Commonwealth Fund demonstration program. This work was under the supervision of Mary Augusta Clark, research statis-

tician of the former Joint Committee on Methods of Preventing Delinquency, and now of the Commonwealth Fund. Advisory statistical service has been given not only to the demonstration clinics but also to the resulting permanent clinics in the various communities. Other clinics as well have shown interest in this work and have sought counsel and help, which is given to the extent permitted by Miss Clark's other duties. *Recording and Reporting for Child Guidance Clinics* (published by the Commonwealth Fund in 1930), represents the accumulation of tried statistical methods of child guidance clinics and is recognized as the standard guide in this field.

RICHARD A. BOLT

Twenty-First Annual Report of the International Association of Dairy and Milk Inspectors—*Compiled by Paul B. Brooks, M.D. Albany, N. Y.: State Department of Health, 1933.*

This report contains much of unusual interest and value, and deserves a wide circulation not only among those directly concerned in the production and handling of milk, but also among health officers and physicians.

We would direct especial attention to the article by W. E. Krauss, of the Ohio Agricultural Experiment Station, showing that according to biological assays, the pasteurization of milk does not injure its nutritive qualities except for a partial destruction of vitamins B and C. Since pediatricians and physicians have generally been furnishing supplementary diets to guard against this, their partial destruction is not a serious problem.

Deserving of special attention is the

symposium on Nutritional Quality Developments in Certified Milk, and the Reports of four Committees on Communicable Diseases Affecting Man, Milk Plant Practice, Sanitary Control of Ice Cream, and Food Value of Milk and Milk Products. The last is extremely valuable, being a critical review of some 71 different articles.

While these have been selected as being of particular interest and importance, the whole report is made up of papers of unusual excellence.

The importance of milk in nutrition is so well recognized and methods of handling it, fortifying it, and modifying it are being proposed so frequently, that all should be glad to have authentic pronouncements upon it.

MAZÏCK P. RAVENEL, M.D.

Research on the Constitution of the Japanese with Special Reference to the Physical Capacity—By Dr. Yukinobu Yoshida, Expert in the Japanese Governmental Institute for Research of Physician Training, "School Hygiene," July, August, September, October and November, 1932, Imperial School Hygiene Association, Tokio, 200 pp.

This report is written in Japanese. The author not only writes of his own researches regarding anthropometry in the last 7 years, but also presents the work of others. Dr. Yoshida studied height, weight, chest girth, the difference of chest girth between respiration and expiration, abdomen girth, upper arm girth, thigh girth, calf girth, back strength, grasp strength, shoulder breadth, hip breadth, chest depth, length of legs, length of arms, pulse rate before and after exercise, blood pressure, lung capacity and thickness of skin, measuring 160,000 school children (elementary, high, and college boys and girls), athletes, soldiers and laymen. Much attention was paid in eliminating error from each item; for

example, error by apparatus or posture, and time difference in measuring height.

The tables of the Japanese averages are from 6 years to 18 years and cover the following items:

- Average height according to the age
- Average weight according to the height and age
- Average lung capacity according to the height and age
- Average chest girth according to the height and age
- Average back strength according to the height and age
- Average increase and recovery of pulse rate after the exercise (20 times the knee bending), according to height and age

Suggestions were given to improve each physical strength, and the importance of chest girth and lung capacity with regard to the health was noticed.

Thus Dr. Yoshida discusses the Japanese constitution from the standpoint of physical capacity, and compares these measurements with those of other nations. He concluded that the Japanese physical capacity is not very low until 17 years, but distinctly low in adults, although there has been an increase in height and weight of Japanese adults 20 years of age, as shown in the following:

| | Height | Weight |
|------|--------|--------|
| 1910 | 61.9 | 114.4 |
| 1920 | 62.4 | 115.6 |
| 1930 | 62.8 | 117.2 |

YUZURU NOZU

The Policewoman's Handbook—By Eleanore L. Hutzel, assisted by Madeline L. Macgregor. New York: Columbia University Press, 1933. 303 pp. Price, \$2.00.

In cities progressive enough to have them, policewomen are important factors in the warfare on crime, particularly as it is concerned with the protection of women and children and the prevention and control of sex offenses. The duties and responsibili-

ties of these specialists in this field of social work have been ably set forth in this excellent book. It discusses such pertinent topics as patrol and inspection, undercover operations, investigation of complaints, criminal law procedure, the preparation of cases for courts, evidence, and detention. Several interesting chapters are devoted to case reports, while appendices give time schedules and sample records. The book is well printed, has a comprehensive bibliography, and a good index. Social hygiene workers should find it of great value.

JAMES A. TOBEY

Why We Do It—A Study of Normal, Subnormal, and Abnormal Human Behavior—*By Arthur R. Daviau, M.D. Boston: Mcador Publishing Co., 1931. 231 pp. Price, \$2.00.*

The author's chief thesis is that, in most instances, people in the practical field of human behavior have taken a theory and then adjusted the facts to coincide. Interestingly enough, the author seems guilty of the same fault for which he criticises others. In the first part of the book, he is particularly critical of Dorsey's work *Why We Behave Like Human Beings*. His criticisms are aimed particularly at Dorsey's interpretations of his material. However, the author also disapproves of the methods used by education, religion, psychology, psychoanalysis, and public health. In most instances he presents no data for his own conclusions which are, for the most part, his opinions.

His willingness to generalize from the statement made by one person is shown by the following (page 215): "A psychologist once said 'The most obscure race of people on the face of the earth today is youth. Nobody understands them.'" On this statement, the author then generalizes and concludes (page 217): "According to psychology, youth is a riddle, an un-

solvable problem; and psychologists, apparently, at least, admit that they can do nothing for youth."

He manifests a rather evident lack of familiarity with his subject in general as indicated by his use of such terms as "subnormal behavior" and "abnormal behavior," neither of which he defines, and also with many of the problems which he discusses, for example, when he states (page 221) ". . . mental defectives who in reality are partially insane."

Interestingly enough, he criticises the educational approach because it is too greatly characterized by the use of psychological principles since (page 41) "The teachings of psychology have been rebuilt in the last decade," it should not have the influence it has in education or the training of children. He regrets exceedingly that eugenics is not given a more important field in the sense that it deserves.

The author also seems to believe that there is an undue tendency (page 80) "to boast of the general lowering of the infant mortality rate in the United States . . ."—and without giving any proof or facts, he concludes (page 81) ". . . one would be justified in believing that our infant mortality rate is being lowered most pronouncedly in and among the mental defectives. . . ." It is surprising that a public health officer, in his desire to emphasize the all important rôle of heredity, would ignore that a great deal of the lowering of the mortality rate is an accomplishment of preventive medicine and not of welfare work among mental defectives, and that such diseases as diphtheria, smallpox, typhoid fever, and the like, are not respecters of race, creed or intellectual level.

Another example of the author's interesting method of drawing conclusions is shown (page 63) in discussing a report on state wards, where he quotes ". . . 64 per cent were

taken away from their parents due to marked neglect; 15 per cent due to cruelty on the part of the parents; 11 per cent due to habitual exposure of children to immorality; 10 per cent were orphans." The author then concludes: "From the above tabulation, it can readily be seen that, discounting the orphans altogether, we have at least 90 per cent of the state wards who are the descendants of mentally deficient parents." This deduction is rather indicative of the author's lack of adequate appreciation of the motivation underlying human behavior.

This is further shown in the following statement (page 82): "From her (public welfare worker) statement that neither the father nor the mother wanted the child, I was inclined to believe that this child was illegitimate. . . ." Unfortunate as it may be, studies of family situations reveal that other than feeble minded parents not infrequently have children they did not desire. Neither is it unusual for the mother of an illegitimate baby to be extremely fond of her child.

In the second part of the book, the author presents his own theory of human behavior and posits as the basis the existence of "psychical (mental) originators and the psychical (mental) center of associations." He mentions in this connection love, virtue, vice, belief, courage, bravery, color, thought, etc. This theory of the author has something of the familiar ring of phrenology.

The author also presents his own theories on sleeping, dreaming, and being awake.

This volume offers little of scientific value to the worker in the field and is but a presentation of a eugenic viewpoint the author himself has developed primarily on the basis of his 5 years' experience as a public health officer and city physician. He presents no scientific research to justify his conclusions

which are, for the most part, opinions and assumptions. The book, however, is very interesting reading, although a great many actively working in the field will disagree with many, if not most, of the author's own theories and his quite general denunciation of most of the existing ones.

FRANK J. O'BRIEN

A Decade of District Health Center Pioneering: A 10-Year Report of The East Harlem Health Center—*New York: Published by the East Harlem Health Center, Inc., and the New York Chapter of the American Red Cross, 1932. 148 pp. Price, \$1.00.*

The East Harlem Health Center is one of the notable demonstrations in New York City showing the advantages of operating a department store in health. When it was started in 1921 it did not have the financial stimulus of a large fund such as Mr. White left to Boston. It did have the backing of the American Red Cross for an experimental period of three years after which five foundations provided most of the money. There was no special building erected to fossilize mistakes in theory before experimental evidence through actual work had accumulated. Eventually, in three remodeled houses, twenty-one organizations found headquarters and certain facilities in common. Having completed a decade of work, it is now proposed to turn this health center over to the city of New York as a going concern to be housed in a special building the city fathers are to provide if and when able to do so.

In readable fashion, this illustrated report tells the fascinating story of why and how the East Harlem Health Center came into being. For one thing during this ten year period, 715,445 clients visited the health center, and going the other way, staff member visits to or on behalf of the residents of East Harlem

totaled 708,091. The total cost was \$316,648 or 22 cents per visit if you want to put it that way. Consequently, or at least very largely so, all sorts of disagreeable mortality and morbidity rates decreased.

W. W. PETER

Laboratory Manual, Methods of Analysis of Milk and Its Products—*Compiled by the International Association of Milk Dealers, 228 No. LaSalle Street, Chicago, Ill.* 461 pp. Price, \$5.00 to public health officials, \$7.50 regular price.

This book, or manual as it is properly called, is the result of two years of work by practical laboratory men who have assembled tests found most useful in the milk or ice cream plant laboratory. The five parts of the manual cover the following subjects: organization of a dairy laboratory; bacteriologic control methods; chemical and physical control methods for dairy products; bacteriologic, chemical and physical tests for non-dairy products; preparation of bacteriologic mediums, standard solutions, indicators, and a useful appendix of handy reference data.

This will prove useful to milk plants which have or are contemplating the development of laboratories, to public health laboratories, and to colleges where instruction is given in dairy methods. A prospectus has been prepared which will be furnished upon request by the Association.

IRA V. HISCOCK

Improvised Equipment in the Home Care of the Sick—*By Lyla M. Olson, R.N. (2d ed.) Philadelphia: W. B. Saunders Company, 1933.* 197 pp. Price, \$1.25.

This is an entirely new revision of Miss Olson's work, first published in 1928. This is small and compact, containing 197 pages and a total of 285 illustrations. The contents of the 60 chapters are well indexed thus making

it very convenient as a reference book.

The subject matter covers every type of appliance and equipment that a nurse might find herself in need of and may not have at hand. The directions for improvising and the many illustrations provide means whereby any nurse can create the equipment she needs. The so often heard and probably just criticism, that a nurse in the home so often requires so many things that she becomes an expense account could somewhat be eradicated if every student nurse became familiar with this book. The suggestions given could also be adapted to the smaller hospitals which do not have finances for expensive equipment.

This book is a fine contribution to nursing education. Public health nurses especially will find it very useful, since their field of work is the home. They will also find that the content would make valuable material for staff education and demonstrations.

However, every nurse, regardless of her type of nursing, will find it very useful and as stated by Clara D. Noyes, National Director of American Red Cross Nursing Service, in her foreword, "We hope, therefore, that this little book finds its way into the schools of nursing of this country and that the students become familiar with its contents before they embark upon their careers." FLORENCE E. SPAULDING

A General History of Nursing—*By Lucy Ridgely Seymer. New York: Macmillan, 1933.* 317 pp. Price, \$2.75.

Instructors of Nursing and students will find that this book contains very definite and dependable information on the history of all types of nursing and nursing organizations. The bibliography shows rare judgment in the selection of material from many sources which gives continuity to the historical data. The book is written in a simple,

straightforward manner with a depth of feeling which inspires one with a desire to cherish each historical event.

The author, appreciating the value of state, national, and international nursing organizations, conveys to the reader very definitely the assistance rendered nurses by their professional affiliations. The graduate will find here much material for refreshing her memory in the history of nursing.

RUBY ROGERS

Hospitals and Child Health—*White House Conference on Child Health and Protection. New York: Century, 1932. 279 pp. Price, \$2.50.*

This book is a splendid report. It is an informative study of what the hospitals are doing for the health and protection of children. The study is divided into three parts:

1. *Hospitals and Dispensaries*—The survey showed that enough beds are available for the care of white children in hospitals but care of colored children is woefully inadequate. The beds for children are not controlled definitely by a pediatric staff. Special internships in pediatrics are few, and the training of nurses in pediatric wards is inadequate. "While the general surgical and medical conditions are well looked after, the care of mental and venereal conditions are not provided for as they should be."

2. *Convalescent Care*—(A) *What is being done:* During 1929, 22,141 children were cared for in convalescent homes, 27 per cent of these homes being affiliated with hospitals. Facilities for the care of the convalescent negro children are not adequate. (B) *What should be done:* There should be more facilities for the care of the convalescent negro and specialized cases in general. The sub-committee gives exhaustive conclusions and recommendations.

3. *Medical Social Service* — (1) There are 554 social service departments in hospitals and dispensaries of

this country. (2) Application of tests to the service now being rendered through social service in medical institutions. Medical social service in the protection of the child and his health must go beyond the child patient, for disease and social difficulties of parents and older members of the family may bear heavily on the child. A total of 1,389 placements in foster homes were made by 153 medical social service departments in 68 cities. (3) The lines along which activities of medical social service should be encouraged are covered well in a section on conclusions and recommendations.

ELDRED V. THIEHOFF

The Rise of Preventive Medicine—*By Sir George Newman, M.D. London: Oxford University Press, 1932. 270 pp. Price, \$3.00.*

This book is made up of the Heath Clark Lectures, 1931, delivered at the London School of Hygiene and Tropical Medicine, the first series given under this bequest. We have often had occasion to speak of the facility and knowledge with which Sir George Newman writes on matters of public health, and it is needless to add that no man could be found better fitted to inaugurate this series of lectures than himself.

Beginning with folk-lore, magic, custom and religion, the author carries us through the development of preventive medicine, which of course includes much of general medicine, physiology and other cognate sciences, down to the present, concluding with a chapter on the collective and communal organization of preventive medicine. Each chapter is preceded by a synopsis. The book as a whole shows an enormous amount of study. It contains many statements, some quoted, and some original, which can well serve as aphorisms. The author considers that the bedrock principle of preventive medicine is anchored in anthropology,

the science of the biological history of man; and holds that folk-lore and magic formed the beginning of the science and art of medicine, in which he agrees with Sir Clifford Allbutt.

Needless to say, Egypt comes in for considerable attention, as it was the focal point at which various civilizations were centered and where cross-fertilization took place. The medicine of that country was a palimpsest of medical learning, though needless to say, it was very much mixed with superstition, demonological lore, and other ideas which blocked progress to a greater or lesser extent. Moses was "learned in all the wisdom of the Egyptians," and almost the first organized documents concerning medicine are contained in what is known as the Mosaic Law. It is Mosaic in origin and texture, the author says, but was formulated between 1400 and 1250 B.C., its earliest records having been written in the 10th or 9th Century by some prophet of Judah, and cast into one form somewhere about 722 B.C. None of the constituent documents were written by Moses, though what he said to the children of Israel might well have been their origin and inspiration. A review of the 8 points made in this Law will convince anyone of its value, and Sudhoff said: "Had Judaism given nothing more to mankind than the establishment of a weekly day of rest, we should still be forced to proclaim her one of the greatest benefactors of humanity."

Greece also comes in for serious consideration, and concerning the Greek spirit, Sudhoff is quoted as saying: "It first clearly grasped the aims and inwardness of hygiene." Drainage for malaria was proposed in this country between 500 and 430 B.C. by Empedocles, "a physician with a practical sense of prevention." All students of medicine recognize how much we owe to the Greeks. Sir Clifford Allbutt

summarized this: "There were for the wiser Greek physician three factors of safety: he was free from magic, he never forgot to treat the individual, he was a master of hygiene."

One is tempted to keep on giving quotations from this excellent presentation, containing much that has been known and forgotten by some and new to many. The author holds that nothing educates people more than sanitation, and stresses preventive medicine in action as an educator of the public, saying that he has known the purification of a water supply in a village to raise the moral standards of the community.

Sir John Simon says of preventive medicine, "It is the province where Medicine joins hands with Common Sense." The last chapter ends by following this great pioneer in urging reliance on the strength of the people for self-help and upon the solicitude of the community for the welfare of its weaker members. "Altruism and kindness of man to man, combined with foresight, true economy and common sense are among the forces which can most wisely apply the verities of the science and art of Preventive Medicine to the needs of men."

This is the most ambitious work which the author has published. Every page is full of meat. The illustrations are fine, and we wish that more pictures of pioneers in preventive medicine might have been given us.

The printing and make-up are what we have learned to expect from the Oxford Press. It is a matter of some regret that although these lectures were given in 1931, they appeared in print late in 1932, and have been received in this country in 1933. There are few books on public health which can be recommended more heartily and completely than this.

MAZÏCK P. RAVENEL, M.D.

General Principles Governing the Prevention of Tuberculosis—By Dr. E. Burnet. *Geneva: Quarterly Bulletin of the Health Organization, League of Nations. Distributed in the United States through the World Peace Foundation, Boston, December, 1932.* 174 pp.

This very comprehensive report is a result of two years of work on the part of Dr. Burnet, who was secretary of a "Reporting Committee" appointed by the Health Committee of the League of Nations to report on the question of tuberculosis control throughout the world.

Dr. Burnet not only drew on articles already prepared, but conducted field studies in Germany, Austria, Denmark, France, Great Britain, Italy, The Netherlands, and Yugoslavia. Unfortunately for the readers in the United States, very little is said about the tuberculosis program in this country or Canada. Dr. Burnet explains this by saying that he had "no direct knowledge of Canada or the United States of America, or of Japan or Russia." However, he says that his intention is not to present a complete picture, but rather to lay down the general lines for efficient organization.

The first premise is that tuberculosis is a "social disease" the control of which is to be effected fundamentally by organized community activity, or what is commonly known in Europe as "social hygiene." It is impossible in a brief review of this sort to state the facts upon which he bases this premise. However, he discusses the decline in the tuberculosis mortality, the reasons for that decline and the social factors which underlie it. His contention is that the decrease in the tuberculosis death rate is a matter primarily of progress in civilization which includes improvements in all social factors plus specific anti-tuberculosis measures undertaken in the various countries.

Concerning these specific measures, Dr. Burnet feels that the dispensary is the important and pivotal agency in the campaign against tuberculosis and that it should become more and more a central clearing place through which all tuberculous persons should pass, and be directed to the care and treatment which is best suited to each case. He feels that the dispensary should not only take cases which come to it, but should go out and seek the people who need care, putting on, if necessary, a thorough case-finding study.

Dr. Burnet traces the revolution which is taking place in sanatoria. At first they were only places where persons suffering from tuberculosis were kept from infecting others. Then came the realization that along with the practice of collapse therapy the sanatoria could become hospitals and great strides made in the curing of tuberculosis in them. The third step was to make the sanatoria great centers from both the medical and preventive points of view, valuable both to the individual and the community. He calls this revolution the "hospitalization of sanatoria."

As to the results of collapse therapy, the author is none too sanguine. He feels that much of this work could be done in dispensaries and that thereby the dispensary could be a center for epidemiological research. He stresses the importance of the nurse in the scheme of tuberculosis control, and discusses the rehabilitation and after care which he feels must be linked up with sanatoria. In this connection he advocates that villages be built around sanatoria for ex-patients which shall serve as health centers.

The author finds that the experiments with BCG throughout the world point to favorable results and ventures the thought that as the years go by greater use will be made of it.

The entire question of bovine tuber-

culosis is discussed, based on studies in several countries. He quotes from Möllers that, "The proportion of bovine bacillus infection to all cases of human tuberculosis is 2.8 per cent" and suggests that it will be wise to abide by the conclusions adopted at the 1912 Rome Congress: "The infection of human beings by the bovine bacillus is much less frequent than their infection with the human bacillus. At the same time the measures recommended against infection by the bovine bacillus should be maintained."

In Part III, the author discusses the political and administrative framework in all the countries under discussion. The first sentence of this section is as follows: "The history of the campaign against tuberculosis shows that the first action was taken by private organizations. The State intervened later on to support and regulate this action." And again, "In no nation has the State directly completely taken over the campaign against tuberculosis." . . . "Private initiative can never be sufficiently far-reaching, methodical or generous to conduct the campaign against tuberculosis single-handed." The question of health insurance as practiced in the various countries is exhaustively discussed.

The fourth section covers the cost of tuberculosis work in the various countries studied. This is very enlightening and very valuable since it brings together for the first time definite figures concerning the amount spent for tuberculosis work.

In conclusion, the author brings together the principles of prophylaxis and gives in fairly brief space the implications of a complete tuberculosis program. One or two quotations are significant: "Tuberculosis is not the only endemic or epidemic disease from which mankind is suffering, but it is the most difficult to eradicate, and on it hygiene will therefore test its power.

If a man can conquer tuberculosis, he will be able to rid himself of the other ills which beset him. The struggle with tuberculosis will be the supreme test of social hygiene."

The reader of this article will learn nothing regarding the tuberculosis program in this country, but he will grasp the fundamentals of tuberculosis control as practiced throughout the world and will feel the trends of that work from an international standpoint. It is a remarkable article and a very important résumé to date of tuberculosis work.

JESSAMINE WHITNEY

The Vitamins in Health and Disease
—By *Barnett Sure, Ph.D.* Baltimore: *Williams & Wilkins*, 1933. 206 pp. Price, \$2.00.

"New discoveries," wrote Dr. Harvey Cushing of medical science in the latter part of the nineteenth century, "were being announced like corn popping in a pan." Much the same condition exists today with respect to research on the vitamins. Results of investigations on these formerly elusive substances are reported so frequently and extensively that the bio-chemists themselves are somewhat bewildered by them. Sanitarians and physicians, who have many things to ponder over, often find it virtually impossible to keep up with the latest important developments in nutritional science.

This book, prepared by an authority in this particular field, will be welcomed as a concise review of modern knowledge regarding the vitamins, which are conceded to be of vast significance to human health. The book is written in a simple style, with no attempt at dramatics. It will appeal to the intelligent rather than the average reader and it should prove of real interest and value to health workers. Occasionally the author has a tendency to indulge in speculation, but most of the material is strictly factual. Like all of the books

issued by this publisher, it is exceptionally well printed. There is a brief foreword by Dr. Walter H. Eddy, whose recommendation of the text to all in-

terested in the relation of diet to health can be seconded by the reviewer.

JAMES A. TOBEY

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Another Glance at the Wages of Diphtheria Prophylaxis—Diphtheria immunizationists will find comfort in the annual tabulation of results, for those cities doing the best work in prophylaxis are, in general, enjoying the lowest mortality rates. Diphtheria is relatively most prevalent in the Southwest which formerly had lower rates than the rest of the country.

ANON. Diphtheria Mortality in Large Cities of the United States in 1932. J.A.M.A. 100, 20:1595 (May 20), 1933.

Typhoid Fever Drops Again—The annual summary of typhoid rates in the large cities concludes with: "Whatever the case as regards rural communities and the smaller cities, it is evident, now that the returns are all in, that the larger cities of the United States experienced no increase in typhoid mortality in 1932 but, instead, a substantial reduction."

ANON. Typhoid in the Large Cities of the United States in 1932. J.A.M.A. 100, 19:1491 (May 13), 1933.

More About Rheumatism—One would suppose that the subject of rheumatism had been pretty effectually explored, but here is another British symposium which works over again the old familiar sod. Included as usual are the health, economic, social and industrial aspects.

BROWN, W. L., *et al.* Rheumatism and Arthritis as a Public Health Problem. J. State Med. 41, 5:250 (May), 1933.

Pointed Aesculapian Philosophy—Much that will give pause to the ardent proponent of preventive medicine will be found in this scholarly dissertation on the philosophy of medical practice. The author pays his respects to the well known Committee on Costs with some delightful banter. Good for all to read.

CUSHING, H. Medicine at the Crossroads. J.A.M.A. 100, 20:1567 (May 20), 1933.

Who Shall Practice Public Hygiene?—Shall educational qualifications for health workers be set up and, if so, who and what shall qualify candidates? These questions are posed but not fully answered in hope that the discussion provoked may bring us one step nearer the solution of this difficult matter.

FERRELL, J. A. Professionalization in Public Health Work. J.A.M.A. 100, 18:1380 (May 6), 1933.

A Doctor Looks at the Baby Clinic—No one doubts the educational value of infant welfare clinics; all know that they help mothers who can afford to pay, says the author. What's the answer? "If a mother knows that her private doctor has a systematized plan of following her child and that he is really interested," she will come to his office by appointment rather than wait "half the afternoon with a swarm of other women and contagious children." After that, there follows some searching

criticism of present conditions in practice.

HILL, L. W. Child Health Conferences and the Doctor's Bread and Butter. *New Eng. J. Med.* 208, 18:942 (May 4), 1933.

Looking for Abortive Poliomyelitis—Methods for the detection of abortive cases are discussed, and the records are made of five small community outbreaks. Clinical poliomyelitis is probably four times as frequent as usual statistics indicate.

PAUL, J. R., *et al.* Studies on the Epidemiology of Poliomyelitis. *Am. J. Hyg.* 17, 3:587 (May), 1933.

Southern Contributors to Public Hygiene—Brief biographies of the leaders in public health who came from, or did their work in, the Southern states. This will furnish useful material for the historically-minded sanitarian.

LEATHERS, W. S. Pioneers in Public Health In the Southern United States. *South. M. J.* 26, 4:306 (April), 1933.

Foreign Views of Our American Diphtheria Propaganda—"We in this country (Great Britain) are apt to look askance at the flamboyant methods of propaganda used by our brethren on

the American continent. . . . The time has come, however, when in the light of results achieved we *must* doff the cloak of ultra-respectability and tackle the job on the lines of the American merchant who, having goods to sell, finds that publicity pays." These sage comments are interlarded in a comparison of British and American methods and results.

NASH, E. H. T., and FORBES, J. G. Diphtheria Immunization: Its Possibilities and Difficulties. *Pub. Health* 46, 8:245 (May), 1933.

Colds by the Boat Load—Another study of colds in an isolated Arctic community reveals the same findings as earlier research. About 48 hours after the first boat in spring, an outbreak of colds begins which eventually includes most of the inhabitants who remain free from colds during the season in which there is no communication with the outside world. None of the organisms of the usual nasal flora seemed important.

PAUL, J. H., and FREEZE, H. L. An Epidemiological and Bacteriological Study of the "Common Cold" in an Isolated Arctic Community (Spitzbergen). *Am. J. Hyg.* 17, 3:517 (May), 1933.

NEWS FROM THE FIELD

SEPTEMBER 1932 AND JANUARY 1933 JOURNALS NEEDED

DUE to unusual demands for last year's September number and this year's January number of the Journal, the Executive Office finds itself in need of several copies of each issue. It would be greatly appreciated if members who can spare these Journals would send them to headquarters. Each member who complies with this request will be reimbursed for the postage used.

DR. RICE AND DR. RUHLAND SAIL

AMONG the 17 guests of the Oberlaender Trust who sailed last month for a six-month study of cities in Germany were Dr. John L. Rice, Health Officer of New Haven, Conn., and Dr. George C. Ruhland, Commissioner of Health of Syracuse, N. Y., both Fellows of the A.P.H.A.

JOURNALS MERGE

THE journals *Archives of Physical Therapy*, *X-Ray*, and *Radium and Physical Therapeutics* have consolidated, retaining the name of the former. These journals were the official organs of the American Congress of Physical Therapy and the American Physical Therapy Association, respectively. The merging of the journals is the result of the amalgamation of the two organizations into the American Congress of Physical Therapy.

HOMER FOLKS GIVES DELTA OMEGA LECTURE AT YALE

THE 1933 Delta Omega lecture at Yale University was given on April 24 by the Hon. Homer Folks, of New York, Fellow A.P.H.A. His subject was "Public Health and Social Service."

GERMAN GOVERNMENT AID FOR SMALL- SCALE GARDENING

THE Federal Government of Germany, which for the last year or two has been aiding the unemployed to establish small gardens, has recently provided another 25 million Reichsmark (about \$6,000,000) for that purpose. Out of this amount loans will be made to communities which in their turn will lend to individuals small amounts, 50-70 Reichsmark (about \$10-17), without interest, to be paid within 10 years. A community is entitled to a loan when it intends to establish a minimum of 20 gardens. The ground for each garden must be of a certain size and is to be selected with a view to the possibility of later adding a house to it.—*Archiv f. Soziale Hygiene und Demographie*, Berlin, Dec., 7, 6, 1932.

STATE CHARITIES AID CELEBRATES

THE Silver Anniversary Annual Conference of State and Local Tuberculosis and Public Health Committees of the State Charities Aid Association was held in New York City June 8-9, in celebration of the twenty-fifth anniversary of the anti-tuberculosis campaign in New York State, outside of New York City, carried on by the State Department of Health and the State Charities Aid Association.

DR. LUEDDE AWARDED BLINDNESS PREVENTION MEDAL

THE Leslie Dana Gold Medal, awarded annually for the most outstanding achievements in the prevention of blindness and the conservation of vision, was presented to Dr. William H. Luedde, Director of the

Department of Ophthalmology at the St. Louis University School of Medicine.

Dr. Luedde was selected for this honor by the National Society for the Prevention of Blindness in coöperation with the Missouri Association for the Blind, through whom the medal is offered annually by Mr. Leslie Dana of St. Louis.

NEW POSITION CREATED IN BALTIMORE

DR. ANTHONY L. RETTALIATA has been appointed Full-Time Medical Health Officer of the Baltimore Health Department. This is a newly created position in the Department.

NEW BUTTER RULING IN CINCINNATI

THE Board of Health of the City of Cincinnati has adopted a regulation which requires that all butter sold in Cincinnati shall be made of cream from tuberculin tested cows in officially accredited areas, and that certification to this effect shall appear upon the label. This regulation will become effective September 1, 1933.

EXTENSION COURSE AT ALBANY MEDICAL COLLEGE

THE Albany Medical College, in coöperation with the New York State Department of Health, devoted "Residence Week"—June 12-17—to an extension course for Health Officers.

The program included papers on epidemiological work, medical care of indigents during the present emergency, newer diagnostic criteria of tuberculosis, typhoid carrier control, water supplies and summer camps, milk control in New York State, childbirth mortality, orthopedic service of the New York State Department of Health, and a symposium on the venereal diseases. Also there were clinics on heart diseases, industrial surgery, syphilis, and undulant fever.

THE BLIND IN PALESTINE

THE British Government is criticized for its indifference toward the blind of Palestine in a report by Subhi Dajani, of Jerusalem, published in the June issue of the quarterly journal of the American Braille Press, international organization which produces and distributes literature and music in raised print for the blind.

"The Government has so far provided no legislation for the relief of the blind. . . . There are three institutions which care for the education of the blind, though not exclusively. The best is the Jewish Institute for the Blind, which is entirely for Jews. The Syrian Orphanage devotes part of its buildings to the housing and education of the non-seeing, and finally there is a Moslem Orphanage. The number of blind in these establishments . . . is 190. . . . The total number of blind in Palestine is given as 5,000, though this does not include the sightless village populations. . . . most of the Moslem blind earn their living by reading the Koran after the dead. The streets abound with blind beggars."

SCIENTIFIC CRIME DETECTION COURSE

NEW YORK UNIVERSITY has announced the establishment of a department of Forensic Medicine at the University and Bellevue Hospital Medical College, to train medical examiners and toxicologists. The new department, one of the first of its kind in this country, is designed as an initial step towards establishing a system of scientific crime detection in this country which may some day rank with the system of medico-legal institutes of Europe.

Dr. Charles Norris, chief medical examiner of the City of New York, has been named Professor of Forensic Medicine and will head the department.

RESOLUTIONS ADOPTED AT THE FOURTH ANNUAL CONVENTION OF THE WESTERN
BRANCH, AMERICAN PUBLIC HEALTH ASSOCIATION,
PASADENA, CALIF., MAY 29-31

RESOLUTION I

WHEREAS: for many years past in this country the mortality and morbidity from preventable causes among the rural populations has remained stationary and exceeded that of the urban population, and

WHEREAS: numerous surveys including that of the New York State Health Commission, show a lack of co-ordinated and sustained effort to remedy these deplorable conditions in rural areas, and

WHEREAS: the only effort being made in such areas is an appropriation by the Federal Government through the United States Public Health Service and the appropriation of a few national private agencies, thus stimulating states and a number of counties to support rural health departments, and

WHEREAS: as a result of such expenditures in rural areas a material reduction in mortality and morbidity rates has occurred in these areas, and

WHEREAS: in the absence of such aid under present rural economic conditions many such efforts will be discontinued, and

WHEREAS: the need of such effort is particularly urgent in the Western states because of the likelihood of introduction of oriental diseases, and

WHEREAS: it has been the policy of the Federal Government to assist states and local communities in rehabilitation programs, and

WHEREAS: the foundation of these rehabilitation programs is the preservation of the public health,

NOW THEREFORE BE IT RESOLVED: the Western Branch, American Public Health Association in regular annual

meeting at Pasadena, Calif., on May 30, 1933, respectfully petitions that the Federal Government continue to recognize this responsibility by the appropriation of adequate funds for full-time county health units and rural sanitation.

RESOLUTION II

WHEREAS: the recent appearance of psittacosis in California and other Western states has established this disease as a distinct menace to the public health, and

WHEREAS: scientific investigations have proved that birds of the psittacine family, particularly parrakeets in California, are infected with this disease, and

WHEREAS: intensive research into psittacosis among psittacine birds in California together with the enforcement of adequate regulations governing the importation of such birds into the United States should necessitate stringent measures in the control of this disease, and

WHEREAS: the United States Public Health Service is rendering invaluable assistance to California and to all other states through the maintenance of its local laboratory for the study of psittacosis and through the enforcement of regulations governing the importation of psittacine birds,

NOW THEREFORE BE IT RESOLVED: that the Western Branch of the American Public Health Association request the United States Public Health Service to continue the maintenance of its laboratory for the study of psittacosis in California, and

BE IT FURTHER RESOLVED, that the United States Public Health Service be requested to take all necessary

precautions to prevent the introduction of psittacine birds into the United States, and

BE IT FURTHER RESOLVED, that these resolutions be spread upon the minutes of the Association and that a copy be sent to the Surgeon General of the United States Public Health Service.

RESOLUTION III

WHEREAS: the Western Branch of the American Public Health Association realizes that, in this period of financial emergency when there is an unusual amount of personal distress and civic unrest, a great effort must be made to maintain the physical well-being of our citizens, most particularly the children, so that the communities may not be endangered by epidemics of communicable disease brought about by malnutrition and bad housing, and

WHEREAS: the Health Departments and their allied health and social agencies of the various communities are charged with the responsibility of maintaining the health and welfare of the citizens and must of necessity, meet the increasing demands brought about by these unusual times,

NOW THEREFORE BE IT RESOLVED: that the Western Branch of the American Public Health Association emphasize to our legislative representatives and various governing boards, the grave emergency that is now being faced by Health Departments and ask their continued and increasing support both morally and financially, and

BE IT FURTHER RESOLVED: that copies of this resolution be sent to the representatives of the above bodies.

RESOLUTION IV

WHEREAS: economic conditions are such as to necessitate maximum efficiency in governmental activities, and

WHEREAS: many of the National Public Health Agencies will upon invitation, assign experts to state and local authorities for the purpose of surveying conditions and making recommendations as to the type of public health organization needed to obtain maximum results with the funds available,

NOW THEREFORE BE IT RESOLVED: that the Western Branch of the American Public Health Association in Annual Meeting at Pasadena, California, May 29, 30, and 31, 1933, bring to the attention of the proper state and local officials in their territory the necessity of this service, the advisability of this service and assist them upon request in contacting proper officials.

RESOLUTION V

WHEREAS: the Colorado Medical Association and the Denver Health Council have sponsored a statewide public health survey by the United States Public Health Service and have initiated legislation designed to improve public health activities throughout Colorado,

NOW THEREFORE BE IT RESOLVED, that the Western Branch of the American Public Health Association commends the actions of the above organizations, and we recommend similar programs for the other Western states.

RESOLUTION VI

WHEREAS: one of the major benefits of national conventions of the American Public Health Association is the activated interest in public health, developed in sections fortunate enough to be hosts to the convention, and

WHEREAS: allocation to some Western portion of the United States is contemplated for the convention next year,

NOW THEREFORE BE IT RESOLVED: by the Western Branch, American Public Health Association in its Fourth Annual Convention assembled, that we join the many public health, medical, and civic organizations in cordially inviting the American Public Health Association to hold its 1934 Convention in Southern California.

SEWAGE ASSOCIATION MEETS AT ROCHESTER

THE Spring meeting of the New York State Sewage Works Association was held at Rochester, N. Y., June 9-10. Papers were presented—on Vacuum Filtration of Sewage, Sewage Aeration, Selection and Maintenance of Mechanical Sewage Equipment—and so on. There was a symposium on Small Sewerage Systems and Treatment Plants.

PERSONALS

H. GRADY CALLISON, M.D., member A.P.H.A., has been elected Commissioner of Health of Richmond County, Ga., with department of health headquarters at Augusta. He succeeds Dr. Eugene E. Murphey, member A.P.H.A., who has retired. Dr. Callison had been Deputy Commissioner of Health for a year, having formerly been Health Officer of Newberry County, S. Car.

DR. ANTHONY J. LANZA, F.A.P.H.A., spoke on "Silicosis in the United States" at a meeting on silicosis held in Chicago June 12, under the auspices of the industrial committee of the Chicago Tuberculosis Institute.

DR. JOHN H. GRAVES, member A.P.H.A., President of the California State Board of Health, was recently appointed medical director of the California State Industrial Accident Commission and State Compensation Insurance Fund.

DR. ADDISON W. PRESTON, of Visalia, has resigned as Health Officer of Tulare County, Calif., after 25 years' service.

DR. RAY C. ATKINSON has been appointed Health Officer of Colfax, Calif., succeeding Dr. David M. Kindopp.

DR. GARLAND H. PAGE, of Salt Lake City, Utah, member A.P.H.A., has been appointed Superintendent of the Utah State Hospital, at Provo.

DR. OSWALD T. AVERY, of New York, member A.P.H.A., has been named President of the American Association of Pathologists and Bacteriologists.

RICHARD A. BOLT, M.D., F.A.P.H.A., has been appointed by the United States State Department as a delegate to the Sixth English-Speaking Conference on Maternity and Child Welfare, to be held in London July 5-7, and also to the Congrès International pour la Protection de l'Enfance in Paris immediately following. Dr. Bolt is making a study of maternal and child welfare conditions in Germany and Austria, as a result of a recent award of the Oberlaender Trust.

DR. JOHN H. HAMILTON, F.A.P.H.A., was recently appointed Director of the North Carolina State Laboratory of Hygiene, at Raleigh, N. C. He succeeds the late Dr. C. A. Shore.

CONFERENCES

June 28-July 3, International Hospital Congress, Knocke-sur-Mer, Belgium.

July 1-7, National Education Association, Chicago.

July 3-7, Association for Childhood Education, Denver, Colo.

July 3-8, British Social Hygiene Council Imperial Congress, London.

July 4, Meeting of the Department of Lip Reading of the National Education Association, Chicago, Ill.

July 5-7, Sixth English-Speaking Conference on Maternity and Child Welfare, London.

July 5-9, International Union of the Protection of Childhood, Paris.

July 10-15, International Council of Nurses, Paris, July 10-12; Brussels, July 13-15.

July 18-20, International Congress of Pediatrics, London.

July 19-22, International Society of Orthopaedic Surgery, London.

July 25-29, British Medical Association, Dublin.

July 29-August 4, World Federation of Education Associations, Dublin.

August, World Federation of Education Associations, Dublin.

September 27-28, Second European Reunion on Mental Hygiene, Rome.

November, 7th American Scientific Congress, Mexico City.

Spring, 1934, Statistical Conference, International Statistical Institute, London.

BACTERIOLOGISTS

Bacteriologist, with fourteen years' experience as assistant director of state public health laboratories, desires an immediate position either in public health, commercial work, or teaching. Has had experience in teaching and public health education. L.L. 540

Bacteriologist, M.S. in Bacteriology and Clinical Diagnosis, University of Washington, Seattle; laboratory experience in private clinical laboratory, State Health Department laboratory, hospital laboratory and in milk research with the U. S. Public Health Service. Available now. 65

Young man desires position as director of laboratory or teaching bacteriology; Ph.D., Cornell University, 1924; teaching experience at Cornell, '17-'24, at Harvard, '24-'26; considerable experience as technician, chemist and director of hospital laboratory. Available now. 66

Young woman, nurse's training, Düsseldorf, Germany; laboratory and X-ray course, North West Institute, Minneapolis; one and one-half years' experience in large city health department, desires position, preferably in the South. 67

HEALTH OFFICERS

Physician desires position as director of health in a city or rural district. Four years' special training at Beirut, Syria, and a course at New York University; four years' experience as County Health Officer. Available now. 68

Young man, M.D., University of Louisville; C.P.H., Johns Hopkins; desires position as City or County Health Officer; one year's experience with county Health Department and three years' experience as city Health Officer. Available now. 69

Physician, M.D., Northwestern University, special course in business administration, desires position as city Health

Officer. Served as industrial physician in steel company; has had two years' experience as city Health Officer. Prefers West or South. Available on six weeks' notice. 70

Physician, graduate of Class A medical college, desires position in public health work. Has had eight years' experience in city and rural health work and sanitation. Available, with reasonable notice, at any time. H.M.B. 72

SANITARY ENGINEER

Young man, S.B. in Sanitary Engineering, Massachusetts Institute of Technology; graduate work, University of Arizona in physiology, advanced bacteriology and organic chemistry; Assistant Water Superintendent and Engineer for a local Health Department and considerable experience as civil engineer on road and dam construction. 71

MEDICAL BUREAU

The Medical Bureau has available class A physicians, dentists, graduate nurses and laboratory workers who have specialized in public health work. All credentials have been thoroughly investigated. Those in need of such personnel may receive complete biographies including statements regarding candidates' ability, integrity, and responsibility. No charge to employers for the introduction of applicants. M. Burnice Larson, Director, The Medical Bureau, Pittsfield Building, Chicago.

POSITIONS AVAILABLE

The next examination for Registered Pharmacists to be conducted by the New Jersey Board of Pharmacy will be held at the State House, Trenton, N. J., Thursday, October 19, 1933. Applicants for this examination must have all papers on file not later than September 19, 1933. Requests for application blanks should be sent to the Board of Pharmacy, State of New Jersey, 28 West State Street, Trenton, N. J.

Loss of Actinic Sunshine as a Health Problem of Cities*

FRED O. TONNEY, M.D., F.A.P.H.A.

Director, Technical Service and Research, Chicago Board of Health, Chicago, Ill.

IN the light of advances during the past few decades, it is becoming increasingly evident that progress in the prevention of air pollution has not kept pace with other public health problems, which but a few years ago lay before the engineering profession. Control of air pollution is still an acute problem of cities, in sharp contrast to its companion projects of water and milk protection, which are now no longer problems, but actualities of accomplishment.

Perhaps the reason for this has been that the pollution of the air by products of combustion has been treated primarily as of economic and esthetic concern, rather than as a basic health problem. It is true that the irritating properties of smoke upon the respiratory membranes and the accumulation of soot in the lungs of the urban dweller have been recited at length as arguments against air pollution; but they have not been sufficiently convincing to bring about a satisfactory solution.

More recently, studies of the loss of actinic sunshine in its passage through the smoke filled atmosphere of cities, have shown a decided and prolonged loss of the ultra-violet light component so necessary to growth of the young and to maintenance of the normal calcium balance of the body.^{1, 2, 3}

The significance of this loss from a health aspect is in need of evaluation and calls for a review of the physiologic needs of the body in respect to ultra-violet light or its dietary equivalent, vitamin D, and for a more general realization of the effects upon health which follow as a result of prolonged lack or insufficient absorption of this important form of vital energy.

The obscuring effect of smoke acts to reduce the intensity of the anti-rachitic and erythematous rays, especially in the winter, but does not always occlude them entirely.

Experiments on rats in New York,⁴ in Toronto,⁵ and in the outskirts of Washington, D. C.,⁶ and on chickens in Boston,⁷ indicate the presence of weak antirachitic rays in winter sunshine of those localities, sufficient to protect these animals in all-day ex-

Read before a Joint Session of the Public Health Engineering and Industrial Hygiene Sections of the American Public Health Association, at its Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

posures. However, attempts to protect babies^{8, 9, 10} from rickets solely by means of winter sunshine, administered both directly and through semitransparent windows, have yielded conflicting results and have been on the whole disappointing, in so far as they are applicable to babies under ordinary living conditions.¹¹ Skyshine¹⁰ as an antirachitic agent during the winter of the temperate zones has proved to be ineffective. Furthermore, recent studies of the solar actinic rays in Chicago, as determined by spectrographic and actinic methods, show that the erythematous and antirachitic rays in the range below 308 mμ. (3080 Ångström units), which are occasionally demonstrable by the spectograph in winter sunshine, are of extremely low actinic intensity.¹²

DERANGEMENT OF THE CALCIUM METABOLISM

Gamble says regarding rickets: "No other disease is nearly as prevalent during the first two years of life."¹³ Holt and Howland also regard rickets as "probably the most prevalent disease of infants, at least in the cities."¹⁴

Climate and Season—Rickets is primarily a disease of the temperate zones and is far more common in cities than in the surrounding rural districts. It occurs chiefly in the winter and late spring, and virtually disappears during the summer. The disease is rare in tropical regions where sunshine is of good actinic quality the year around, and also in polar regions where the solar ultra-violet light deficiency is offset by general use of raw fish oils in the diet.¹⁵

Hess and Lundagen report that both normal and rachitic babies in New York¹⁶ show a seasonal tide of calcium and phosphorus in the blood—from a normal in summer of 11 mg. of calcium and about 5 mg. of phosphorus, to a low ebb in March of 9 mg. of calcium and

3.6 mg. of phosphorus per 100 c.c. of blood. Similar findings have been observed in Germany¹⁷ and in New Orleans.¹⁸ Older children in New York also exhibited this ebb and flow of minerals in the blood during the period of low and high actinic quality of sunshine.¹⁶

Utilization of Calcium—The physiological effect of ultra-violet light is apparently exerted by absorption into the skin, principally through the agency of ergosterol, by which it is converted into a catalytic principle, vitamin D. This principle circulates in the blood and is also stored in certain organs, such as the liver and glandular tissues.

Deficiency of vitamin D in the body expresses itself as failure to absorb and utilize the lime and phosphorus of the food, with resulting want of lime in the tissues. In the blood, the deficiency is recorded as low blood phosphorus rather than as decidedly low blood calcium.¹⁹ The phosphorus appears to be essential to lime retention, since, without it, the lime is largely excreted unused, while the body continues to suffer from want of lime.

Lime is deposited in the bony structures mainly as the insoluble tricalcium phosphate. It is absorbed from the intestines and circulates in the blood in the more soluble forms, such as calcium bicarbonate and calcium acid phosphate.¹⁹

Interesting speculation on the mechanism of absorption of lime salts from the food has been inspired by the work of Yoder,²⁰ Bacharach and Jephcott,²¹ and others, who report that in rickets the bowel contents are relatively alkaline and ultra-violet light or vitamin D lowers the pH, rendering the intestinal contents more acid. The greater solubility of lime salts in an acid medium is well recognized. This premise is in need of further substantiation, but for the present there is no

better hypothesis to explain the observed effects of vitamin D on lime absorption.

PHYSIOLOGICAL NEEDS

The needs of the body for lime salts may be classified conveniently as: (1) Those of the periods of heavy calcium demand, namely, (a) growth, (b) expectant motherhood, (c) lactation; (2) those of tooth development and preservation; (3) those concerned with the resistance of the body to bacterial invasion.

Growth—The excessive demands of the infant and growing child for lime, to make bones and teeth and maintain bodily health, are scarcely in need of reiteration, beyond the too little realized fact that rickets is still widely prevalent. The disease is of a milder form, however, than a few years ago, due in a measure to partial correction of the solar deficiency by use of cod liver oil, irradiated foods, and artificial ultra-violet light.

The prevalence of rickets in groups of children in various cities has been reported as 96 per cent in New Haven,²² 25 per cent in New York,²³ 95 per cent in Boston,²⁴ and 19 per cent in Pittsburgh. In Chicago, during 1931, 16 per cent of the children of preschool age examined routinely were found to present visible evidences of rickets.

Daniels and Hutton²⁵ conclude from an extensive series of "calcium balance" tests on children, that "infants should retain 40 to 50 mg. of calcium and 20 to 25 mg. of phosphorus per kilogram of body weight."

Expectant Motherhood—The needs of the expectant mother, to meet the calcium requirements of the growing fetus for bone and tooth formation, seemingly have not been fully appreciated. Calcium balance experiments on expectant mothers, in different parts of the world, have thrown interesting light on this need.

Coons of the University of Chicago,²⁶ in a study of 9 expectant mothers, found that 6 were suffering from a "negative calcium balance," that is, were not absorbing from their food and retaining the additional lime needed by the developing babies. This was true more generally in the overcast season of the year. The corollary is that lime from the mother's own bones and teeth were being drawn upon to supply the baby's needs. Further evidence of this appeared in the clinical condition of the mothers, and in at least one of the infants born in a "pre-rachitic" state.

Similar experiments during the prenatal period, by Hoffstrom,²⁷ Landsberg,²⁸ Macy, Hunscher, et al.,²⁹ have also clearly established the excessive calcium demands of pregnancy.

A striking demonstration of the need of expectant mothers for lime and phosphorus is reported by Kathleen Vaughan.³⁰ Under a religious custom as practiced in India, girls of the upper classes are kept shut in out of the sunlight from an early age until some time after marriage. They live in darkened houses, though there often are inner courtyards, and are not allowed to go out unless heavily veiled. They have no exercise. During pregnancy these women develop a severe form of bone softening known as osteomalacia, due to their failure to absorb sufficient lime and phosphorus from their food to meet the excessive demands of the prenatal state.

The symptoms are severe, "boring" pains in the bony ring of the pelvis and in the ribs, a peculiar waddling gait and inability to climb stairs due to flattening of the softened pelvic bones, crumbling teeth, tetany or convulsions due to calcium deficiency, and occasionally spontaneous fracture of the long bones. Many die in childbirth, being weakened, deformed, and extremely susceptible to the natal infections.

In contrast to these women of the

higher castes, are the "boat women" of the poorer classes who live and work out-of-doors with the men. They are fine physical specimens, and during pregnancy give no evidence of calcium deficiency, or any of its distressing symptoms. Being continually out-of-doors in the sunlight, they are able to absorb the needed lime and phosphorus from their food, whereas their presumably more fortunate sisters of the Purdah system are unable to do so.

Tests on animals show quite definitely that pregnancy increases the normal calcium demand and often brings about a condition of "negative calcium balance," in which lime from the mother's body must go to supply the needs of the fetus.^{31, 32}

In Breslau, a study of some 350 expectant mothers was recently reported by Freund and Schmitt,³³ indicating that the use of artificial ultra-violet light greatly improved the calcium metabolism of the expectant mothers, and was reflected in larger, stronger babies at term, with less rickets afterwards.

Lactation—Lactation is another function of maternity which throws a heavy demand for calcium upon the mother's body and greatly increases her need of actinic sunshine, or its equivalent from artificial sources or in the diet.

Prior to the birth of the offspring, the normal mother stores great quantities of lime to be used for secreting milk. This excessive calcium demand continues during the entire lactating period. Here again, ultra-violet light and vitamin D play an essential part in abstracting the needed lime from the food. Deficiency of ultra-violet light or vitamin D in these mothers reduces the retention of lime, and necessitates the disintegration of the lime-bearing structures of the mother's body to supply the needed minerals for milk production. At times, this source fails after a period, and the milk becomes of poor quality.²⁹

The Teeth—The needs of the teeth for lime salts, both for initial growth and for protection from decay, are another little appreciated public health problem. The researches of Mellanby and others have shown an extremely high prevalence of defective first or temporary teeth of rachitic type in the children of England, and an almost equal degree of defectiveness of the permanent teeth.³⁴ Microscopic studies of the teeth of rachitic puppies showed a lack of lime in the layers of tooth substance laid down during deficiency of ultra-violet light and vitamin D.³⁵ Furthermore, when the deficiency was corrected, only the new layers of dentine received the normal quota of lime, leaving the older layers still deficient. The vacuoles, or openings, in such defective teeth are called "interglobular spaces," and it is noted in microscopic examination of decaying teeth that the decay begins in these spaces and defective areas and extends thence into the surrounding tooth structure.³⁴

Resistance to Bacterial Invasion—The lime requirements of the body, for resistance to bacterial invasion, are little understood. The mechanism by which protective substances are formed in the blood is still subject to speculation, the theory that the normal alkaline reserve of the blood plays the star rôle, running ahead of most others.

The clinical fact is that children and adults with disturbed calcium metabolism are an easier prey to bacterial infection than are normal persons. Rachitic children, as a group, acquire the ailments of childhood more easily and have a higher fatality rate from these infections, than do normal children.³⁶ The same is true of experimental animals.³⁷ The Purdah mothers of India, previously referred to, are especially susceptible to infection during labor, according to reports of obstetricians attending them.

In further confirmation of these facts are the respiratory death rates in the larger cities, which have a seasonal ebb and flow, quite comparable to that of the blood calcium and phosphorus of babies and children, reaching a peak in March, at the end of the low actinic period, and falling from that time on, to the minimum in June, July and August.³⁸

In Montreal, studies of the seasonal incidence of contagion by Cushing led to the belief that the stronger actinic sunshine of these months in some way acted to bring contagion to a low ebb.³⁹

Maughan and Smiley, in studies of the incidence of the common cold among the students of Cornell University over several years, came to the conclusion that ultra-violet light deficiency was a factor in predisposition to these infections in "cold susceptible" persons.⁴⁰

THE REMEDY

This, then, is our public health problem, dealing with the calcium derangement of a significant part of the urban population, due in the last analysis to deficiency of actinic sunshine during a considerable portion of the year. The normal seasonal duration of deficient sunshine of perhaps 2 or 3 months, appears to have been at least partly provided against in nature's plan, by storage of vitamin D in the tissues of the body. The prolongation of this seasonal low period by 2 to 4 additional months, due to occlusion of actinic sunshine by smoke, is probably a factor in bringing about the unfavorable physiological reactions of calcium unbalance. Such a conclusion seems reasonable, since evidences of calcium derangement are far less prevalent in rural than in urban districts. As to specific remedies, we suggest:

FIGURE I

Daily Variation of Ultraviolet Light Indicated by Actinic Measurements for the Hour 12-1 PM

- 1. Climatic surveys of cities to determine:
(a) the normal seasonal actinic deficiency. This can perhaps be most simply accomplished by measuring the angle of incidence of the sun's rays at noon⁴¹ and recording the number of months of the year in which it is below 35° from the horizontal; (b) determination of the actinic loss of sunshine due to smoke, which is estimated by comparison of simultaneous readings in urban and nearby rural testing points. For this purpose there are available the simpler actinic methods^{42, 43, 44} and the portable spectrographic method¹² now developed to a practical stage for field work.
- 2. Education of urban populations in the health value of the out-of-doors, with specific information on the local daily actinic value of sunshine, Figures I and II, the hourly variation according to the season, and the minimal erythral time for untanned skin, the latter of which can be easily determined by the device shown in Figure III.
- 3. Provision of substitutes for actinic sunshine, such as ultra-violet lamps in infant welfare centers and free distribution of cod liver oil or vitamin D foods during the prolonged overcast season. Cincinnati,⁴⁵ Pittsburgh, and Chicago have been using some of these measures.

But in all such attempts to meet an acute human need, are we not begging the question? Did the warning to "boil the water" really go far to prevent typhoid fever, while unsafe water continued to flow into city mains? Did the advice to boil the milk really check the conveyance of bovine tuberculosis in a significant way, while pasteurizing plants and tuberculin testing of herds were still remote and visionary projects?

We know they did not. There is ever a substantial number of persons who disregard advice, who cannot afford treatment, who neglect to follow a precautionary program consistently. What we need most is pure water for *all*—the unthinking as well as the informed; safe milk for *all*; clean air; and the full actinic value of sunshine at all seasons of the year for the *entire population*.

We must turn for our remedy to the public health engineer. We can now

FIGURE II

Daily Variation of Ultraviolet Light Indicated by Actinic Measurements for the Hour 12-1 PM

FIGURE III

DEVICE TO RECORD ERYTHEMAL TIME

The child is placed in direct sunshine for 40 to 50 minutes, with shoulders covered by cloth.

Each of the openings in the opaque strip is covered successively at 5 minute intervals with a paper sticker—beginning at the left.

Thus, a series of exposures of 5 minutes, 10 minutes, 15 minutes, etc., up to the maximum, is made. After 12 hours, the erythema spots are counted from the right, back to the last visible mark. This number, subtracted from the total number of openings exposed, and then multiplied by five, gives the minimal erythema time.

In Chicago, during June, the mean erythema time was 20 minutes—in both children and adults.

offer a health motive for the clearing of the skies, a motive as fundamental and far reaching as those that have brought about the control of water-borne and milk-borne disease. Our children mean much to us—as do our mothers and mothers-to-be. Do they mean enough to spur the correction of imperfect and wasteful methods of combustion?

There are certain trends of heating practice springing up here and there which seem to point the way. The central steam heating plant to burn coal and oil in congested centers is now successfully competing with individual heating plants, driving the smaller heating units out of use. One can see this development now in process of evolution in the business section of Kansas City, Mo., with a noticeable effect upon

air conditions. Do not the same economic principles apply to cities everywhere, and on a larger scale?

Should government go into the business of providing heat for its populations without pollution of the air, in great central plants connected by underground pipes to every building in the respective districts? Or is this service a function of private enterprise, profitable on an extended scale, as well as in a limited way?

Should there be underground conduits like the aqueducts and sewers, to carry objectionable fumes of combustion and industrial processes to a common treatment plant or discharge them at a safe distance?

What can be done to increase the use of natural gas for heating and indus-

trial purposes in those centers in which it is available? The combustion products of gas heating do not materially occlude the sunshine.³⁸

What is the hope of electric heating in the future, especially where hydro-electric power is within reach, or where coal fields, adjacent to water supplies, are within 200 or 300 miles, near which coal could be burned and converted into current?

THE RÔLE OF THE ENGINEER

The ultimate disposal of this newer health problem of air pollution falls to the lot of the public health engineer, just as others have done—problems of equal initial proportions, but which have in the end proved to be more colossal in prospect than in the accomplishment.

The engineering profession has never failed to provide the way, once a definite health dictum has been laid down for its guidance.

Hats and Stethoscopes

THE influences which bring about the abandonment of time-honored customs are varied and often surprising. An editorial in the British Medical Journal brings out one of the most curious of these.

In England, the top-hat has been for generations the dignified insignia of the physician, and even country doctors, winter and summer, wore it. The medical attendant of the Victorian era considered it the only hat appropriate to his dignity, and we are told that, in addition, he found it a convenient receptacle for his one-piece stethoscope, so much so that Sherlock Holmes would

recognize a doctor's "topper" by the bulge in the crown.

Now this dignified headdress has departed from the medical field, though it is still the professional emblem of stockbrokers, undertakers and bank messengers.

What has brought about the change? It is credited to the motor car chiefly, but partly to the World War. People have gotten used to seeing their family physician in almost any kind of costume. The doctor is certainly to be congratulated on his additional comfort.—*British Medical Journal*, June 3, 1933, page 971.

Is Malnutrition Increasing?

ESTHER JACOBS

Executive Secretary, Community Health Center, Philadelphia, Pa.

RECOGNIZING the wide variance of opinion with regard to the entire subject of malnutrition, and appreciating that the basis of diagnosis differs with each individual physician, we deem it wise to state at the very beginning that we propose only to show what we have found in studying our diagnoses of malnutrition on clients coming to the Community Health Center diagnostic medical clinics during a five-year period.

The Diagnostic Clinic is only one of the activities of the Community Health Center, which also includes a Dental Clinic, giving complete treatment service; a Mental Hygiene Department, giving both treatment and diagnostic service to a limited number of patients; and a Health Extension Department, which carries on an educational program. The clients are referred by the constituent social agencies in the Federation of Jewish Charities, with the exception of a very small group examined each year for the Mothers' Assistance Fund. Both family and childcare agencies (including day nurseries) are represented. The patients are almost all Jewish. They are a dependent group of individuals, referred for periodic health examinations semi-annually or annually, depending on the age of the client and the referring agency, so that a certain proportion have been coming back at regular intervals over this five-year period. The agency referring the case assumes full responsibility for supervision of the client's health follow-up.

The Community Health Center medical examiners are practicing physicians of experience and standing in the community, who give us clinic periods on a paid hourly basis. The work is under the direction of Dr. Bernard Kohn. The appointment system is followed. Each new patient sent to us is preceded by as complete a medical history as the case worker is able to secure, plus any significant

the Community Health Center, or because of some illness which occurred during the interval between examinations, is usually sent to the Community Health Center by the case worker at the time such treatment is completed.

The medical staff based their diagnoses of malnutrition on clinical find-

* New cases means those patients seen for the first time at the Community Health Center. In this group there has been a very definite increase since 1930. The proportionate increase in malnutrition diagnoses from 1928 to 1932 in the new cases was 82.3 per cent.

CHART III

DIAGNOSES OF MALNUTRITION AMONG COMMUNITY HEALTH CENTER PATIENTS, MAY TO OCTOBER, INCLUSIVE, FOR EACH YEAR (IN PERCENTAGES OF TOTAL NUMBER OF OLD CASES *)

making of this study brought out general agreement among the physicians as to the diagnosis. Since the staff was materially changed between 1929 and

* Old cases means those previously known to the Community Health Center and re-examined for the first time in that fiscal year. New cases in 1928 become old cases in 1929, and so on, for each succeeding year. Therefore, although there is no duplication in the data for the individual year, the old cases necessarily are cumulative.

It would seem from this material that the percentage of malnutrition according to Community Health Center diagnoses was higher in old cases than in new. However, the proportionate increase over the five-year period is lower in the old cases.

1930, the same question was put to our former staff members, each of whom stressed the same points in defining the basis for a diagnosis of malnutrition.

The study covered the five-year period, 1928 to 1932, taking all individuals examined during the first six months of the fiscal year, May to October inclusive, which brought the material practically up to date. The data are shown in the following table.

diagnosis above what they would ordinarily have been; also, the staff of physicians was slightly different during 1928 and 1929 than during 1930, 1931, and 1932. However, as previously stated, the individual examiners agree that their basis of diagnosis is the same, and this would seem to be more or less borne out by the fact that there is no startling difference between 1929 and 1930, which might

There has been a gradual increase in malnutrition diagnoses from 23 per cent in 1928 to 36.5 per cent in 1932, or a proportionate increase for all cases of 56.5 per cent.

During 1928 and 1929 a nutrition worker on the staff may have made the physicians more nutrition conscious during those years, and may have possibly increased the malnutrition

be expected with a change in examiners.

Among the old cases returning to the Health Center regularly over a period of years are a large group from broken homes. Just what part poor heredity and what part the emotional factors play in these cases where malnutrition persists must undoubtedly be considered in the problem as a whole.

In addition to the age division as

CHART IV

DIAGNOSES OF MALNUTRITION AMONG COMMUNITY HEALTH CENTER PATIENTS—MAY TO OCTOBER, INCLUSIVE, FOR EACH YEAR (IN PERCENTAGES ACCORDING TO DIFFERENT AGE GROUPS)

presented in Chart IV, we also classified the groups according to sex, but found only a slight variation in that respect.

It seems important to emphasize the gradual upward trend over the entire period, rather than the percentage in any one group at any particular time. However, from the study it would seem that the more serious problem here definitely centers about the six to sixteen year old group. The rather erratic up-and-down curve in the seventeen to twenty year group is probably explained on the basis of the very small number of individuals in each subdivision in that particular age group; while in the group over twenty the fact that lack of adequate or proper diet does not develop symptoms as quickly as in children would affect the total picture and make it less spectacular, though probably just as serious in terms of future well-being.

Is there not some significance, and should we not be concerned, in such an increasing number of malnutrition diagnoses, and the possible causative factors? Is it due to physical defects and poor heredity, or, has the depression, with its lowered standards of living—involving inadequate food budgets and overcrowded living condi-

tions—been largely responsible? In either case can we lose sight of the possible effect of the emotional element as a cause in malnutrition? The insecurities and conflicts which arise when unemployment strikes at the very foundations of family life surely might conceivably be a very basic cause and one not so amenable to treatment.

From many sources we hear how the health of the nation has been main-

DIAGNOSES OF MALNUTRITION IN OLD CASES EXAMINED AT COMMUNITY HEALTH CENTER, MAY TO OCTOBER (INCLUSIVE) 1928—1929—1930—1931—1932.

| Year | Total Number of Old Cases | NEW Malnutrition on OLD Cases | | PERSISTING Malnutrition on OLD Cases | |
|------|---------------------------|-------------------------------|--------------|--------------------------------------|--------------|
| | | Indi-vid-u-als | Per-cent-age | Indi-vid-u-als | Per-cent-age |
| 1928 | 1421 | 81 | 5.7 | 288 | 20.2 |
| 1929 | 1502 | 111 | 7.3 | 300 | 19.9 |
| 1930 | 1309 | 66 | 5. | 296 | 22.6 |
| 1931 | 1253 | 75 | 5.9 | 319 | 25.4 |
| 1932 | 1145 | 127 | 11.1 | 320 | 27.9 |

tained at a high level, and this is most encouraging when one realizes the fundamental part the public health movement has had in bringing it about. Such proof, particularly at this time when budgets of health activities are being so drastically reduced, is especially needed and helpful and must not be minimized. However, in his presidential address before the American Public Health Association last October, Dr. Louis I. Dublin, in stressing the favorable health condition throughout the country, injected this thought: "I should, however, point out that our records throw no light on the mental health of the people, which must be anything but good. Nor can I avoid the fear that, should present conditions

continue, we will soon become aware of the consequences of malnutrition of children in terms of disease and mortality records."

How serious the inroads upon the general health have been during this period of depression, and what eventually will be the cost to communities in the future, one can only speculate at this time. Health activities must continue, and more than ever before we must think and plan in terms of positive health. Mental hygiene, periodic health examinations, dental care, correction of physical defects, carefully planned and well-rounded food budgets, must all play a large part in our health programs if we are to safeguard our future generations of children.

The Physician's Prayer

ME also Thine eternal providence hath chosen to watch over the life and health of Thy creatures. I am about to begin the exercise of my profession.

Aid me, O All-kind One, in this great work, so that it may be of avail, for without Thine assistance nothing succeeds, not even the least.

May the love of my fellow-man and of my art ensoul me. May not thirst for gain nor craving for fame mingle in my service, for these are enemies of truth and charity, and they might mislead me, and keep me from doing what I ought to do for the weal of my fellow-men. . . .

If wiser men wish to teach and correct me, may I follow them and be

grateful; for the compass of our art is large and wide. But if zealous fools upbraid me, then let the love of my art keep me strong, so that I may adhere to truth without regard to years and fame; for weakness and yielding would involve the pain and even the death of Thy creatures. . . .

Give me frugality beyond all, except in the great art. May never awaken in me the notion that I know enough! Oh give me strength and leisure and zeal to enlarge my knowledge, and to attain ever to more. Our art is great, and the mind of man presses forward for ever.—Extracts from *The Physician's Prayer* (Maimonides), *The Canadian Medical Association Journal*, January, 1931, page 2.

Seasonal Distribution of Whooping Cough for Periods of High and Low Incidence*

G. E. HARMON, M.D., F.A.P.H.A.

*Department of Hygiene and Bacteriology, School of Medicine,
Western Reserve University, Cleveland, Ohio*

THE present study undertakes to compare the seasonal distribution of whooping cough during periods of high and low incidence. The data utilized are those which have been described and evaluated in a previous paper,¹ namely, the reported monthly incidence of whooping cough for various states of the United States as published in *Public Health Reports*. The years 1922-1931, inclusive, are considered. A time series composed of the number of cases of whooping cough reported in successive months, adjusted throughout to a month of 31 days, was set up for each of 29 states. These adjusted time series constitute the basic data of this study.

The first problem is that of defining a period of high incidence and a period of low incidence. Each time series, running from October 1, 1922, to September 30, 1931, includes 9 epidemiological years. As a first attempt the year of maximum incidence was considered a high period. The results of an analysis carried out upon this basis were not satisfactory because of irregular fluctuations due apparently to small numbers. Greater stability was necessary in order to get reasonably

smooth seasonal curves. To secure this, the 3 years of greatest incidence were considered a high period and the 3 years of lowest incidence a low period. In reality, the percentage monthly distribution of the combined cases for each 3-year period represents the seasonal distribution of a mean year of high and low prevalence respectively.

To obtain the percentage seasonal distribution for all states, two methods were tried. Method I involved the combination of the various individual time series. In other words, the 29 states were regarded as a morbidity registration area. The 3 years of highest incidence were picked out from the composite time series thus derived. Then the figures representing the corresponding monthly incidence for the selected years were added together. Method II involved (a) picking out the 3 years of highest incidence from the time series of an individual state first. Then (b) the figures representing the corresponding monthly incidence for the selected years were added together. The monthly figures thus obtained for each of 29 states were similarly added together to get a composite picture of distribution of cases by months for all states considered as a whole. Finally, in both methods the combined cases for each month were expressed as a per-

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

centage of the grand total for the high period. Percentage seasonal distributions of cases for a period of low incidence were obtained by applying these methods.

In using Method I it is probable, since the epidemic cycles of the various states do not vary together, that high and low years are combined and the effects of either averaged out. With Method II the calendar years selected for either period respectively are not the same for the various states. For all states, however, the years selected for each period do in a sense represent

corresponding positions on their epidemic cycles.

The results obtained by applying these methods are set forth in Table I and Graph I. A study of these indicates that during a high period, as here defined, the seasonal distribution of whooping cough tends to exhibit a greater amplitude and an earlier peak than during the low period. The question naturally arises as to whether this result may not be due to the weight exerted by a few large states. This possibility was investigated as follows: After applying the first two steps of

Method II (a and b) to the time series of a state, the combined cases for each month were expressed as a percentage of the grand total for the 3 years. The percentages thus obtained for a high

peak for Illinois, Maine, Michigan, Oregon, New York, and Vermont comes earlier than March; and the peak for Connecticut, Florida, Louisiana, Maryland, Missouri, North Dakota, and Wis-

Graph I. Seasonal Distribution of Whooping Cough. 29 States Combined.

GRAPH I

Graph II. Seasonal Distribution of Whooping Cough. Method 2.

GRAPH II

and for a low period were plotted on a single diagram so that they could be directly compared. Such a diagram was prepared for each of the states.

The peak of the seasonal curve for the high period for Alabama, Arkansas, California, District of Columbia, Kansas, Massachusetts, Minnesota, Mississippi, Nebraska, New Jersey, North Carolina, Ohio, Pennsylvania, Tennessee, Washington, and West Virginia comes in March or April. The

consin comes later than April. The group with an early peak includes northern states in the main, while the group with a late peak includes both northern and southern states. The shape of the seasonal curve for a high year does not seem to be associated with any definite geographical area. In a previous paper on the subject of whooping cough¹ dealing with a year of median incidence, a similar conclusion was reached.

For both high and low periods the minimum month was quite consistently October. In contrast to the relative constancy of the peak month of curves for the high periods and of the low month of curves for both periods, the peak month of curves for the low periods was found to vary a great deal. This was brought out in the following way. The states were classified according to the location of the peak month of the low-period curve relative to the peak of the high-period curve as a standard. On this basis and taking into account the general shape of the low-

period curves, the states fell into one or another of 4 groups.

The combined figures for Pennsylvania, Ohio, New York, and Wisconsin (Group I), are presented in Table II and Graph II. The low-period curve is characterized by a late peak, a low amplitude and is bi-modal.

Table III and Graph II show that for Group II, comprising Kansas, Michigan, Illinois, Maryland, Alabama, North Carolina, and Tennessee, the low-period curve has a late peak but is not bi-modal. Its amplitude is less than that of the high-period curve.

Group III (Table IV and Graph III) includes California, Minnesota, Massachusetts, Florida, Missouri, Mississippi, New Jersey, and Oregon. The peak of its low-period curve coincides in time with that of the high-period curve but its amplitude is less.

Group IV (Table V and Graph III) includes Washington, Connecticut, Arkansas, Louisiana, District of Columbia, North Dakota, West Virginia, Nebraska, Maine, and Vermont. The low-period curve is a bit irregular, due perhaps to small numbers, but its peak

comes earlier than that of the high-period curve. Its amplitude is less.

SUMMARY

During periods of low incidence the seasonal distribution of whooping cough exhibits less amplitude than during periods of high incidence. For 11 states (Groups I and II) the peak of the low-period seasonal curve is later than that for the high-period curve; for 8 states (Group III) the peaks of the 2 curves come at the same time, and for 10 states (Group IV) the peak of the

The Fence or the Ambulance

JOHN N. HURTY, M.D.

'Twas a dangerous cliff, as they freely confessed,
Though to walk near its crest was so pleasant.
But over its terrible edge there had slipped
A duke and full many a peasant.
So the people said something would have to be done,
But their projects did not at all tally,
Some said, 'Put a fence 'round the edge of the cliff';
Some, 'An ambulance down in the valley.'

But the cry for the ambulance carried the day,
For it spread through the neighboring city;
A fence may be useful or not, it is true,
But each heart was brim full of pity
For those who slipped over that dangerous cliff;
And the dwellers in highway and valley
Gave pound or gave pence, not to put up a fence,
But an ambulance down in the valley.

'For the cliff is all right if you're careful,' they said,
'And if folks even slip or are dropping,
It isn't the slipping that hurts them so much
As the shock down below when they're stopping.'
Then an old sage remarked, 'It's a marvel to me
That people give far more attention
To repairing results than to stopping the cause,
When they'd much better aim at prevention.

'Let us stop at its source all this mischief,' cried he,
'Come, neighbors and friends, let us rally,
If the cliff we will fence we might almost dispense
With the ambulance down in the valley.'

'Oh, he's a fanatic,' the others rejoined.
'Dispense with the ambulance? Never!
He'd dispense with all charities, too, if he could;
But no! We'll protect them forever;
Aren't we picking folks up just as fast as they fall?
And shall this man dictate to us? Shall he?
Why should people of sense stop to put up a fence
While their ambulance works in the valley?'

But a sensible few who were practical, too,
Will not bear with such nonsense much longer,
They believe that prevention is better than cure
And their party will soon be the stronger.
Encourage them, then, with your purse, voice and pen,
And (while other philanthropists dally)
They will scorn all pretense and put up a stout fence
On the cliff that hangs over the valley.

Epidemiology of Syphilis and Gonorrhea*

WILLIAM L. MUNSON, M.D., F.A.P.H.A.

State Department of Health, Albany, N. Y.

ONE year ago I had the privilege of presenting to you a record of some outbreaks of syphilis and gonorrhea which had come under my observation over a period of years. I wish now to present more recent investigations.

There is not too much education but too little actual epidemiology; not too much attention to treatment of cases known but too little prevention. There should be a real constructive program rather than just palliation. Just as with other communicable diseases we must have a case finding machinery—and when cases are found something must be done about them. The reason progress is so slow is because of our prudery and our false sense of modesty.

You know as well as I, that when we talk smallpox, typhoid or undulant fever, we talk it right out. We get the information. We collect the data, and we never ask ourselves questions about the propriety of our actions. When it comes to syphilis or gonorrhea we hush it and pass it by. We begin to qualify with ifs and ands and buts—we wonder if it is not too delicate a thing really and purposefully to investigate. Silly shame takes hold of us and we think silence is the best way out.

Dr. Ruedemann of our staff in New York State pointed out this salient difficulty in a talk on syphilis and

gonorrhea when he quoted Bernard Shaw: "We live in an atmosphere of shame. We are ashamed of everything that is real about us, ashamed of ourselves, of our relatives, of our incomes, of our opinions, of our accents, of our experience, just as we are ashamed of our naked skins."

Another reason for failure in this field of public health endeavor is that we just do not do it, assuming that we cannot get the facts—so why bother very much?

May I present an actual experience to show precisely what I mean?

Questioning of a patient in a V. D. clinic:

State Nurse: "Where did you get your infection?"

Patient: "I won't tell you."

State Nurse: "But you have got to tell me."

Patient: "Well, if you must know, I got it from George —."

Local Nurse: "You never told me that."

Patient: "You never asked me."

What public health official would have the supervision of a typhoid outbreak and content himself with lectures on the disease? He would investigate every case minutely; every contact would be subjected to careful scrutiny. The source of infection would be diligently sought and controlled. Why not the same procedure with syphilis and gonorrhea? Is it not now considered good public health and preventive medicine to investigate the single case

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

of smallpox or typhoid? Do we wait for an epidemic? Don't we make quite a fuss about these single cases? Don't we look up contacts and keep them under observation, knowing full well that big epidemics from single cases grow? Is syphilis any different in any of its epidemiological implications, manifestations or behavior?

Any communicable disease is entitled to the amount of attention that its prevalence and harmfulness to the human race demands. I need not tell you what the magnitude of the problem is which syphilis and gonorrhea present. Estimates and figures vary, but these diseases are well up in the list of morbidity and mortality. We all know that they rank high as destroyers of human happiness. I wonder if they have not frustrated as many careers as some of the other diseases to which we give much more attention. Surely the misery and anxiety which they cause, taken with the financial cost for both early and late treatment and institutional care, make the problem of their abatement one of paramount importance to the tax payer.

Last spring I started out to see if as a routine measure I could pick up the trail and dig out of communities their problem so far as these diseases were concerned. I do not believe that the data and tracings submitted are anything unusual or peculiar. If these investigations had not been made probably no one would have known that the diseases existed in these communities; that is, not until some very serious happening occurred. I feel quite sure that the experience in my district is nothing unusual but can be duplicated in any given community from time to time. Of course, one can gloss over the situation by ignoring it, but it cannot be done forever. The bill has to be paid in the end and the longer payment is postponed the more difficult is the final and inevitable settlement.

The real investigator and epidemiologist finds his leads in many ways. Every human activity is of interest to him when he is on the hunt. When science is on the track of truth it scorns nothing, no matter how remote, that may have a bearing. The thing most desired in the investigator is the ability to know what is spurious and what is real information. Just a casual remark was the reason for the start of one of the investigations I am reporting in this paper.

KEY TO READING OF TRACINGS

The greatest source of information in getting leads to investigate, in my experience, is the public health nurse. She knows the community in which she works, and its people. She is one person who knows most of the troubles and difficulties of the families under her care, and she is the one who does most toward the solution of these problems. Physicians, if you are on friendly terms with them, will give leads that are of the greatest value. Looking up the card reports of clinics is profitable; they are worth careful scrutiny. Not

every one, of course, will give a lead that is worth further labor. Laboratory reports, too, should always be consulted—frequently they are the source of real clues and useful information.

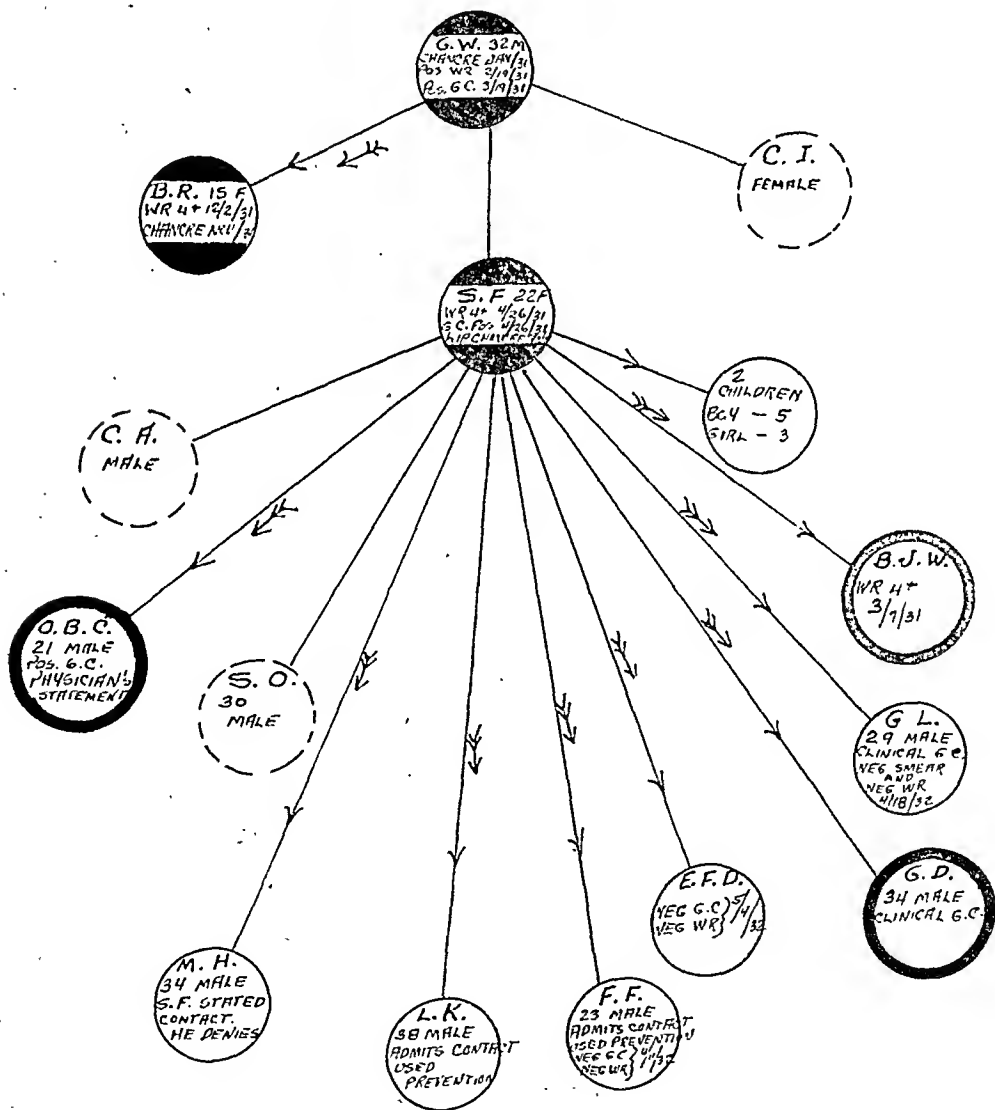

The tracings herewith submitted are selected from 19 investigations recently made and chosen because it is thought that they point out some particular phase or type of investigation either from approach or methods. In 15 of

these 19 investigations the source of infection was discovered.

TRACING I

This outbreak occurred in a village, population about 6,000, and a city of 20,000 population.

The investigation of these cases resulted from a discussion with the local nurse concerning the prevalence of syphilis in her community. She stated that she knew S. F. as a person who might be a source of infection.

TRACING I

EPIDEMIOLOGY OF SYPHILIS AND GONORRHEA—VILLAGE, 6,000, AND CITY, 20,000

She made the initial investigation which I followed up by further investigation and interviews with this person. The data acquired were turned over to a nurse and trained worker who continued the investigation.

Information indicated that G. W., a male in a nearby city, was the first case in this series. His chancre occurred sometime in January, 1931. The infection was transmitted to S. F., a female, and she had a lip chancre in the early part of February, 1931. She was given some treatment at that time but it was not continued. The investigation brought her under treatment again and she has adhered to it since.

The tracing indicates the contacts of S. F., some of whom developed gonorrhea. These cases were taken care of by a physician who admitted the diagnosis but would give no further data. This woman had a positive gonococcus smear April 26, 1931.

Of particular interest is the fact that E. F. D., a contact, was found to have moved to Newark, N. J. This was taken up with the health commissioner, Dr. Craster, of that city and he reported that the man had "been located, examined and found negative. This was fortunate for him for he admitted having been exposed to the disease. Thank you for advising us of this possible menace."

G. W. was also the source of infection for B. R., 15 years of age, female, residing in the city, who had a chancre November, 1931, and positive Wassermann December 2, 1931. When the nurse discovered this girl she had a temperature of 103° F., which followed the birth of a live child which her mother had burned up in the furnace. No physician had been in attendance and apparently a premature birth had been produced. The nurse felt it her duty to obtain a physician to care for this unfortunate girl.

In attempting to do this a very interesting sidelight on syphilis was obtained. The nurse called upon a doctor and asked him to take the case. He refused, saying that he did not care for that kind of case. He, however, plied the nurse with questions and continued the conversation with her saying, "You are going at this syphilis business in the wrong way—you should try to prevent it." Not long before, he had had a letter from the dean of the college attended by his son stating that the boy had syphilis and was under treatment. The girl with whom the boy kept company had been sick for 2 months, but syphilis in this family was a thing not to be thought of—no Wassermann had been taken. The doctor told the nurse that he did not know what to do, but finally he went to the girl's physician and stated the facts. A

Wassermann was then taken which was 4-plus. Treatment was started and the girl promptly began to get well. Syphilis is no respecter of persons. Every once in a while, every doctor should read Osler's dictum, "Know syphilis in all its manifestations and all things else clinical will be added unto you."

This was the only instance in this series in which the police power was used. G. W. was taken in by the police, told that unless he continued his treatment he would be put under arrest, and the facts of his relations with B. R. were given to the district attorney of the county.

While the most of these contacts occurred in the village of 6,000 population, the first 3 cases, B. R., G. W., and C. I., were in an adjoining community of about 20,000 population.

TRACING II

This is a gonorrheal outbreak in a rural population of about 100.

The situation in this community was brought to light when I was discussing with persons in another county the situation as regards the control of syphilis and gonorrhea. We were then investigating an outbreak of syphilis in that community. The remark which caused this investigation was: "We are no worse in this county than they are in ——— county. There is one community there where everyone has it." Inquiry determined the location of this community and investigation with the health officer brought to our knowledge the situation here detailed. Later a trained worker from the department, Julia MacPhillips, completed the investigation. She is the worker employed on most of these investigations. It is upon her data that the tracing is based.

L. M. came to the home of P. H., a well-to-do farmer, as his housekeeper. Within a short time this man was required to go to the hospital due to a severe urethritis which was found to be gonorrheal. Interviews with the 18-year old housekeeper brought out the story that she had received her infection from C. M. before she had come to her present location, while living in another community some 22 miles distant. She gave the names of the contacts to the nurse, who was able to see that she got to her physician who continued treatment.

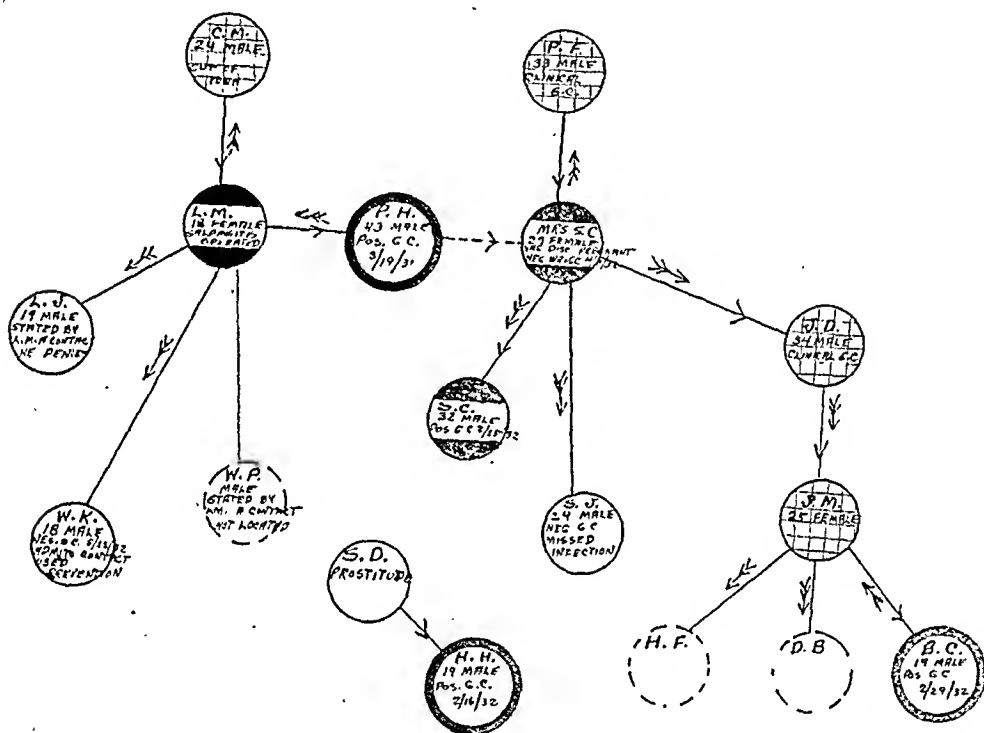

Mrs. S. C., whose husband S. C. developed gonorrhea with a positive smear, was thought by the investigator to have received her infection from P. F., an old gonorrheic. The infection may have come from P. H., because of a happening which occurred in the fall of

1931. It appears that Mrs. S. C. had carried on some negotiations with P. H. which had been discovered by her husband. He became very much incensed but later when the depression became more acute, suggested to his wife that she reestablish relations with P. H. and "shake him down for some coin." I am inclined to think this was the cause of the infection.

J. D. received his infection from Mrs. S. C.

trolling gonorrhea. Apparently she thought that there was an attempt being made to get her brother into trouble because of the hired girl being a minor. At any rate, P. H. was married to L. M., apparently at the insistence of his sister.

In this tracing there is evidence that gonorrhea was introduced into this community on two occasions—by L. M., which spread to others, and by H. H., in which there

TRACING II

EPIDEMIOLOGY OF RURAL GONORRHEA

and apparently transmitted it to his wife, J. M. Neither of these persons was under treatment except what they gave themselves. Mrs. J. M., in turn, transmitted the infection to B. C., who had a positive smear.

At the same time, another case, H. H., age 19, appeared, which to all indications had nothing to do with the epidemic. His story shows that he had gone to a nearby city and 3 days after his visit had gonorrhea with a positive smear. From the evidence there can be no question that this case was an infection got in the city from a prostitute.

In the case of the housekeeper for P. H. there seemed to be some difficulty on the part of his sister to understand that the investigation was solely for the purpose of con-

trolling gonorrhea. Apparently she thought that there was an attempt being made to get her brother into trouble because of the hired girl being a minor. At any rate, P. H. was married to L. M., apparently at the insistence of his sister.

TRACING III

This series of cases was found by the nurse, a trained worker, after Dr. B. had told her that one of his patients had acquired disease out of town. The doctor did not want to give the name of the patient. The only information was that the girl who was the source of the infection worked in a restaurant in a nearby city; that the girl's nickname was "Peggy," and that she had a sister who

probably worked in a factory in the same city.

With this information the nurse located P. D., age 25, and found out that she had gone to a clinic in the city in September, 1931, had requested a Wassermann, and had returned several times to get a copy of the report, which was negative. Her desire to have this report was stated to be that some man had accused her of giving him a disease and she wanted to prove that she was all right. The nurse then called at the girl's home and on the family, which is considered a very respectable one. Arrangements were made by the nurse to have a personal interview with this girl. She gave the names of 3 other persons, all of whom were checked up and found to be under the care of the clinic or a private physician.

While this girl was never found to have

a positive smear, she had infected L. P. A. with both gonorrhea and syphilis. This was the only possible source of infection he had had. When he presented himself first the doctor considered that he had just a gonorrheal infection which seemed to persist, and at a later date the patient showed a secondary syphilitic rash and it was not until this time that a Wassermann was taken. This points out the necessity of taking a Wassermann on all patients with a venereal history. The doctor thinks that probably his patient had an intra-urethral chancre which he missed at the time of his first examination.

There is a history that the girl, P. D., at Christmas, 1931, had a sore in the vagina which lasted some time and which was probably a primary chancre, although at that time she attributed it to the use of a douche

TRACING III

EPIDEMIOLOGY OF SYPHILIS—CITY, POPULATION 20,000

which was too hot. She has been put under treatment which she is faithfully following in the clinic in the city.

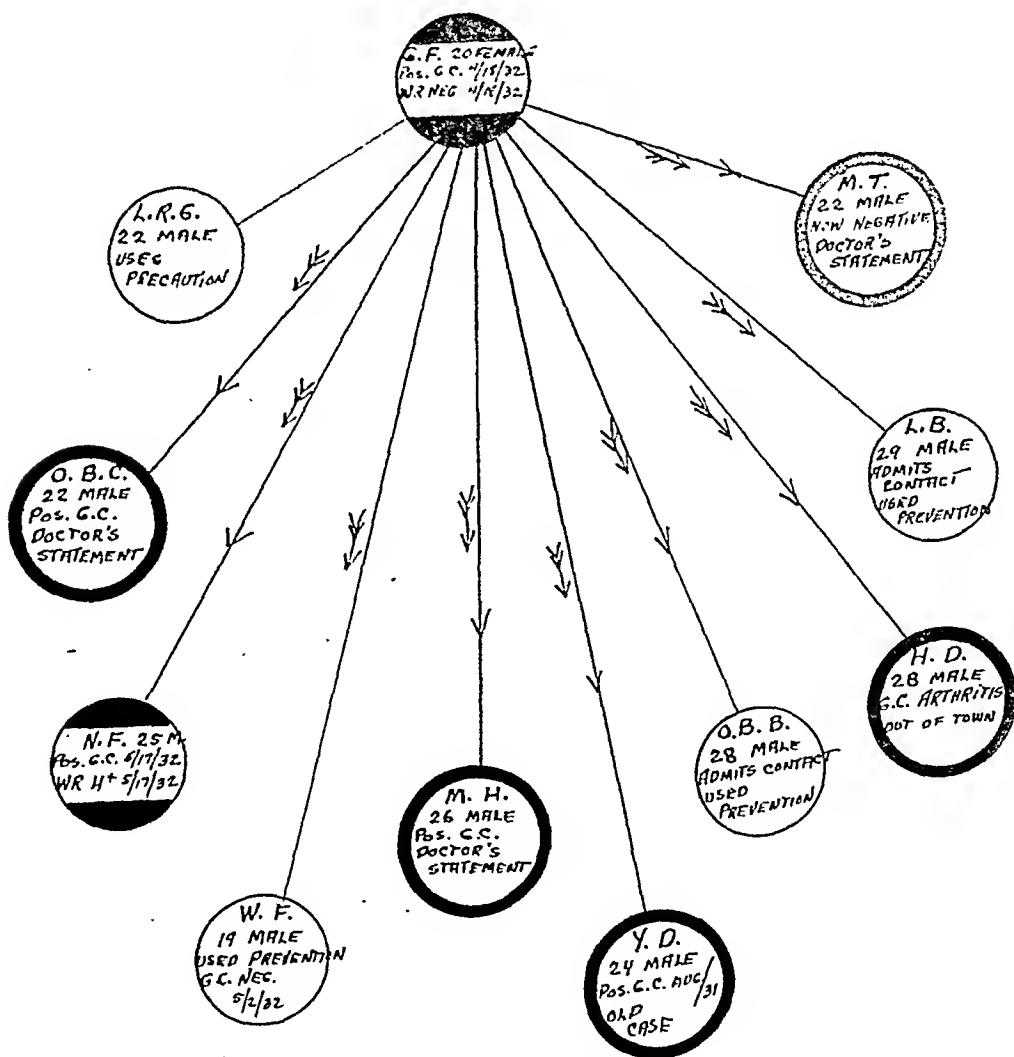

The important lessons of this investigation are: (1) Always take a Wassermann. (2) That physicians will refer their private cases for investigation if they have confidence in the worker.

TRACING IV

This series of cases occurred in a village of approximately 6,000 population. The girl who was the source of infection was discovered because in making another investigation the nurse heard her name mentioned several

times, and local inquiry brought out the fact that she was promiscuous. She had come in June, 1931, from a village some 30 miles distant from her present abode. She stated that she has been infected for 2 years.

The nurse pointed out to her the danger she was in the community, and stated that her only object in coming to see her was to be of service and to get her under treatment. She gave complete confidence to the nurse and informed her of the contacts which are noted. Arrangements were made by the nurse to have her treated by the private physician of her choice and at her own expense since she was earning a good salary. She has conscientiously followed her treatment and so

TRACING IV

EPIDEMIOLOGY OF GONORRHEA—VILLAGE, 6,000

far as we have been able to ascertain has infected no one since.

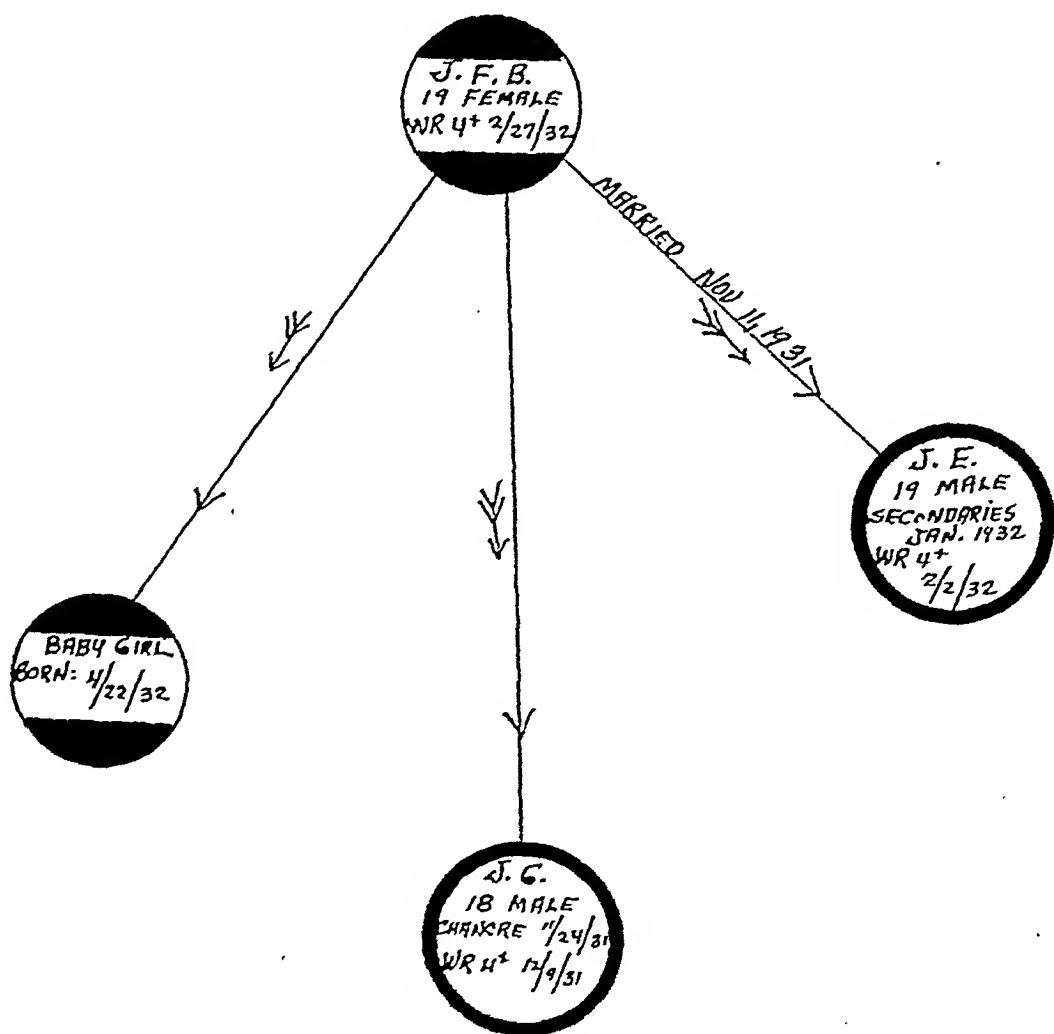

TRACING V

This tracing represents family syphilis in a group of people living 3 miles off the State Road in a rural section. The source of infection of these cases came from out of the state in March, 1931, to live with her mother who was the housekeeper in the family.

This girl had contact with J. G., who developed a chancre November 24, 1931, and a Wassermann taken December 9, 1931, was positive. On November 11, 1931, she married a cousin of J. G., who developed secondaries in January, 1932, and had a positive Wassermann February 2, 1932. Primary chancre was

not noted in this case. The girl is full-blooded white while the two men are each quarter-colored.

These men both reported to a doctor in a nearby village when their trouble began and have been under treatment by him. This doctor worked out the epidemiology involved and suggested that the girl come in for treatment, but this she failed to do. The next known of the situation was when the county nurse obtained information which led her to make a prenatal visit on this girl. She made inquiries which aroused her suspicions and consulted with me; I then checked up with the doctor and found out the story detailed here. The prospective mother was promptly put under treatment but not sufficiently early to prevent syphilis in her baby,

TRACING V

born April 2, 1932. This baby had snuffles, was puny, marasmic, had cranio-tabes and also a peculiar rash which looked like sudamina. It was promptly put under treatment. The skin cleared up, the snuffles ceased, and the marasmic condition improved until the child became the picture of health.

This series of cases points out one of the difficulties which private physicians feel—that they do not think they can go ahead and make investigations looking to get contacts under treatment lest they be accused of having a commercial interest. It seems to me also to prove the necessity for the investigation of cases of syphilis. The probabilities are that if this nurse had not found the girl as a prenatal case she would have continued without treatment; the baby would have had no treatment, and would have died. Further, it shows again that syphilis is carried from one community to another; in this instance from one state to another.

TRACING VI

The history of this family is reported because it shows another method in which one can come upon the trail of syphilis.

B. M., age 7, was reported from a village school as suffering with alleged pink eye. The nurse became suspicious and reported the matter to the county nurse, who with the school nurse took the case to the local family physician who referred it to an eye man in a distant city. This specialist made the diagnosis of interstitial keratitis, had a Wassermann taken, which was 4-plus, and then an investigation was begun of the family. Mrs. B. V. E., mother of the child, was found to have a 4-plus Wassermann. Her husband, 49, was negative, as were her 3 children, ages 3 and 4 years, and 4 months, respectively.

There is a history that Mrs. B. V. E.'s mother was syphilitic, and the contention of the attending physician was that the syphilis

TRACING VI

EPIDEMIOLOGY OF FAMILY SYPHILIS—VILLAGE, 5,000

was congenital in Mrs. B. V. E.; also in B. M. Investigation was made of the grandparents on the mother's side. The grandmother, age 81, showed a negative Wassermann on two tests. There had been 12 children in her family. All were alive and well except 3 who died in adult life, the cause of death being not definitely known in any. The grandfather, age 84, 3 years before, had a fractured hip, at which time he went to a hospital, but no Wassermann was taken. A year later he went to another hospital in the same city for a prostatectomy. There is no record that a Wassermann was done at this time.

Mrs. B. V. E. had no previous knowledge of her syphilitic infection. She denied any extra-marital or pre-marital intercourse that might account for her disease. She was married at 25, and it was 6 years before her first child was born. She had wanted a large family and was disturbed because she did not become pregnant. This sent her to numbers of physicians to see what the trouble was, none of whom took blood for a Wassermann test. She had no miscarriages, no sores on her body, or rash of any kind.

Here are 3 persons in this family who came under medical treatment and a Wassermann was never done on any until we began our investigation. If, in the case of the mother, a Wassermann had been done by one of the physicians whom she had consulted because she was not having babies, she could have been treated and the necessity of treating her present 7 year old daughter averted. If we could get physicians into the habit of taking Wassermans we would unquestionably discover a lot of syphilis and save a lot of money which has to be expended on treatment for syphilis that could be easily prevented.

TRACING VII

This tracing is submitted because the original case was found in a routine prenatal clinic, due to the fact that a Wassermann was taken on the mother who had had two miscarriages. D. I. was 4-plus on April 28, 1932. She was given 3 anti-syphilitic treatments before her baby was born, June 7, 1932, but the child died a week later, apparently of syphilis. Because of the Wassermann taken in the prenatal clinic, there was no investigation of the husband until I had stumbled upon the report seeking to work out some studies in the epidemiology of syphilis, and it was only then that he, B. H., was found to have a 3-plus Wassermann. Both are now under treatment.

It is apparent that where positive Wasser-

manns are found the contacts should be checked up. No public health worker could think of seeing a case of smallpox or typhoid and neglect to search out those who might be infected among the contacts. It seems that this is almost axiomatic. It is difficult to see how failure to do this could be construed as anything but disregard of a plain duty.

TRACING VII

EPIDEMIOLOGY OF FAMILY SYPHILIS— VILLAGE, 800

It would be interesting to tell you of the cases of syphilis which we have found in some outbreaks of smallpox. I saw one where a school bus driver had pustular smallpox and, in between his smallpox lesions, the papular lesions of syphilis. This man was traced by his smallpox and the children under his care had all been vaccinated in time to prevent infection. Back-tracking this man to the nearest genitourinary specialist showed that he also had a positive Wassermann.

There were 3 other cases of syphilis in smallpox patients, one of which was a mistaken diagnosis and is a most intriguing story. My Montreal paper was sent to our clinic directors. One replied that he thought the epidemiology of syphilis a very questionable thing. It seems that a patient was sent

to this doubting Thomas, who was also health officer, by another physician, with a diagnosis of smallpox. He noted the lesions and found a sore throat. He became suspicious of syphilis, took a Wassermann which was 4-plus, and then this health officer investigated the family and found that the husband and children were free from syphilis, but that about 8 weeks before a boarder had come to the house. This boarder had been to a physician and been treated for a venereal disease. He then escaped to parts unknown and has just been located, but no Wassermann has been taken. This health officer is now conducting investigations into the source and interviewing contacts of both syphilis and gonorrhea.

The question of who is to do the field work in the epidemiology of syphilis and gonorrhea brings up the discussion of the qualifications required in such a person. There are certain people who are just not fitted to make any sort of epidemiological investigation. They work hard but they do not get anywhere. They have not the knack of getting to the thing that is pertinent and do not know what the really pertinent thing is—always finding the irrelevant and immaterial. What we need is a trained worker in epidemiological methods in syphilis and gonorrhea. This particularly trained worker should be the teacher of the general all-purpose public health nurse. The place to learn and teach this is in the field. At present in New York State all of our group instruction to the local nurses for this year is on gonorrhea

and syphilis, and due attention will be paid to the epidemiology of these diseases.

My own idea is that the will-to-do, plus a certain amount of self-confidence in the investigator that he can do it, is most necessary. I have had one experience with a nurse who did not see how she could possibly ask these questions and do this work. She was told that she would not get anywhere with a negative approach and afterward became convinced that she could do it, and then went out and did one of the best pieces of work I have seen.

The best "thrillers" have by no means been selected from the number of investigations made. There is one investigation in which a divorce occurred and in which the infected woman gave the testimony on which it was granted. The husband in the case refused to give blood for a Wassermann. I reviewed the testimony and then saw the Supreme Court Justice who conducted the suit. I showed him my data which involved the infection of some 10 persons. I told him the husband had refused a specimen to which the judge replied: "Doctor, you are entitled to take blood from ————. If he refuses tell him that I shall cite him for contempt of court."

No definite attempt is made here to arrive at any conclusions. The items which might be stated as conclusions are so apparent that to recite them seems unnecessary. The attempt made in this paper is to point out that the epidemiology of syphilis and gonorrhea is possible and can be done.

NOTE: See *Discussion* of this article on page 808.

DISCUSSION

EDWARD S. GODFREY, JR., M.D., F.A.P.H.A.

*Director, Local Health Administration, State Department of Health,
Albany, N. Y.*

THE paper which Dr. Munson read at Montreal last year, besides creating something of a sensation drew a challenge from some of the group of specialists in the field of venereal diseases and social hygiene. Among other things they pointed out that most or all of the epidemics Dr. Munson cited had occurred several years before.

The claim was made that conditions are different now and that as much follow-up is being done as is consistent with the social factors peculiar to the venereal diseases.

Dr. Munson has answered these criticisms by investigating recent cases and in doing so has demonstrated how inadequate the usual follow-up is. That every one of his investigations has proved fruitful or worth the time spent upon it cannot be claimed—certainly not in terms of immediate results. But the pioneer often fails to pick the shortest and easiest road to his objective. It is to be expected that those who follow will make improvements or find a better way. And so in the epidemiological method. The unproductive lines can be discarded. It seems to me inadvisable, for example, to pursue very far the illicit sex rela-

tions of persons of the underworld.

On the other hand, merely to examine the family contacts of venereal cases is to fall far short of what is not only feasible but a necessity, if the ill effects of these diseases are to be materially reduced. A dictum which I think should be burned into the mind of every health officer is that investigation is a necessity in the control of communicable diseases; that there is no control without investigation.

The investigation necessarily must be adapted to the particular diseases. The investigation of typhoid follows a different line from that of smallpox. It must also be adapted to the purpose we have in view. In smallpox the emphasis is on prevention, in measles on amelioration of the effects.

One of the functions of epidemiology as I conceive it, is not merely to find out things about the disease, but to devise methods of investigation and means of applying the knowledge.

The great value of Dr. Munson's paper is in its putting the venereal diseases before us as *communicable diseases* and its straightforward attempt to hew a path which others may follow and probably improve as we gain experience and wisdom.

Practical Uses of Diphtheria Immunization Records*

EDWARD S. GODFREY, JR., M.D., F.A.P.H.A.

*Director, Local Health Administration, State Department of Health,
Albany, N. Y.*

RECORD keeping is probably the pet aversion of the physician. Some at least, carry it with them to the health department when they become health officers. Other so-called "practical" people object to making, collecting, and tabulating records on the theory that it wastes their resources.

Referring to records of immunization one finds these "practical" people saying that "records do not get children immunized"; that "I can use the people needed to keep records to get more children immunized." Both are mistaken. Records do help to get children immunized and they can do more effective work than could be purchased for the same cost in direct action.

In the first place it is needful to know who among a group of children have been immunized in order to save the efforts of canvassers. Canvassing has proved the most effective method in securing immunizations, but it is expensive. The possession and use of properly kept records will save their cost of this item alone. Even if unpaid volunteers are used, as sometimes in a "drive," the cost may be saved. Neither volunteer nor professional relishes visiting households that have already been immunized and

serious damage to morale may result from failure to sort out the immunes.

The record of the individual is also useful in determining whether a reported case of diphtheria received his full course of injections at the time and place stated. In a number of instances when this claim has been made it has been possible to show that the time was much less remote than stated; that they had less than the full course of injections; or that they were not there at all. The record is also of use as proof of the individual's having received the required series of injections. These are demanded by not a few summer camps and playgrounds.

Records help to get children immunized in another way. The tabulation of the records tells the health officer, and enables him to tell the community authoritatively, where it stands—how much has been accomplished and how much remains to be done. It substitutes a definite figure for a wishful guess.

Some years ago, following an "intensive drive" along the lines then necessary, the leader of this drive announced that 90 per cent of the children of the city had been immunized. Although there had been enough noise and confusion seemingly to immunize the entire county, a skeptical state health department questioned the figures and asked for the records. After eliminating duplicates and correcting

* Read before the Epidemiological Section of the American Public Health Association, at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

errors it was found they had achieved the very creditable figures of 35 per cent of the under-5 age group, 65 per cent of those 5-9 years, and a little over 30 per cent of the 10-14 group. It was a very successful "campaign" and seemingly it stopped diphtheria, but a hard boiled tabulation of their records showed there was still work to be done.

The officials of another city making large claims for immunization work were becoming skeptical of its value. According to them they had immunized some 30 to 40 per cent of the younger children and nearly 100 per cent of the older ones. Had they kept up their pace and their method of calculation it would have been a matter of only a few years until they could have shown over 100 per cent in the first group and 200-300 per cent in the second. They overlooked the fact that children *do* get older.

I am aware of the claim made by some that they can "make a pretty close estimate" from the amount of T-A they give out. Toxin-antitoxin and toxoid are furnished to physicians free of charge in New York State, the result being that unquestionably some of it is wasted. While there are probably few who inject the entire contents of a 5 c.c. bottle for each shot as one elderly gentleman was found to be doing, yet there are not a few who use but 1 dose out of a bottle in their private practice. Not having many to inject at the same time they prefer to get a new bottle for each injection rather than risk contamination. At clinics nobody ever keeps count of the bottles that are tipped over, those that break, the needles that clog and suddenly let go with an attendant shower under the ministrations of an enthusiastic nurse or physician. Furthermore this method fails to tell us how many individuals got the injections or how many got a complete series of injections. I have no idea what the actual ratio is of c.c.'s

of T-A or toxoid per person receiving a complete series.

Under the stimulus of actual figures health officers with a sense of responsibility strive to better a poor showing; those with a good one try to maintain it, if they cannot improve it. Records get children immunized in that way. Immunization figures enable us also to determine the effectiveness of the various methods employed in getting children immunized. By cutting out useless procedures we have that much more time for useful ones.

The drive I have previously mentioned as having been led by an optimistic estimator, reached its climax after 3 months of publicity. Talks to organizations and new articles were spread over this period with a not very well organized canvass near its close. The result was good. A month later the health officer of another city organized a campaign with 100 volunteer canvassers 16 days before the first clinic was to be held. His newspaper publicity started at the same time. The first clinic was held in the worst blizzard of the winter but despite this handicap the attendance strained the capacity of the arrangements. The results as shown by the records were somewhat better than the longer, more elaborate and more expensive campaign in the first city.

By tabulating and studying the results with varying educational methods, in varying quantities we were soon able to determine that the canvass and a public clinic were *the essential* elements in a drive; that elaborate newspaper propaganda got very little return without them; that school drives got school children but very few younger children; that dog teams, posters, lectures, letters, postcards, merely served as a background; that it took a face-to-face talk and the existence of a free clinic to get children to a clinic or the family doctor in appreciable numbers. The records

also showed that doctors immunized more children during an active drive with a public clinic being operated than they did in all the rest of the year; that the mass movement of children to clinics gave the impetus needed to overcome the inertia of procrastinating parents.

Records will also show which canvassers are successful and which unsuccessful in securing immunizations. Sometimes poor ones can be taught, sometimes they can be enthused into becoming good ones. If they cannot be, they may be good at something else.

The foregoing comments refer to the immediate uses of records. But there is a more remote and I believe a more important use. A year ago I read a paper before the Health Officers Section wherein I advanced the following hypothesis:

1. The attainment of a high degree of herd immunity among children 5-9 and 10-14, as evidenced by the injection of 3 doses of toxin-antitoxin in 50 per cent or more of the members of these groups, produces no definite effect on the diphtheria incidence in that community. Diphtheria if prevalent continues prevalent for a considerable period and declines gradually as it does when active immunization is not used. If not prevalent an outbreak of considerable proportions may arise.

2. However, when the immunization of approximately 30 per cent or more of the children under 5 years is superimposed, there is an immediate definite decline in the current prevalence, and if the community be free from the disease or if its prevalence be low, an outbreak is very unlikely to occur. In other words, there is a critical point in the under-5 age group which must be attained and sustained in order to affect the diphtheria rate favorably.

It should be clearly understood that the foregoing is a mere hypothesis—important if true. It is based on a limited number of observations within a restricted area. It requires further observations of a similar nature from a wider area. Such observations, to be of value, must be based on knowledge of

where the community started from as well as where it ended.

To determine the starting point means that records of immunization must be kept by the health department as a routine. Their everyday uses justify this. They should be classified by age, perhaps by certain areas, at regular intervals, and when unusual circumstances arise. Starting to collect immunization records after an epidemic has commenced is futile unless it is known that there were none to collect.

At least once each year the immunes must be re-classified by age. As previously remarked, children do get older. A record that stood at 100 per cent of the under-5 age group January 1, 1927, would have been exactly zero per cent January 1, 1932, if no immunizations had been done in the meantime. The important thing to the health officer is not where he stood a few years ago, but where he stands now. Reclassifying the ages is not difficult if a system be followed. That used by the New York State Health Department is described in the article previously referred to and in the *Rural Appraisal Form* for 1932. I know of none that is simpler.

While it is purposed to continue observations in New York State as opportunity arises, yet diphtheria outbreaks have become so infrequent that unless decided change occurs it will be many years before sufficient evidence accumulates to provide an ample test. There has not been what might be termed a "satisfactory" outbreak in the state since a year ago last winter and no area of high endemic prevalence for over 2 years. Of necessity, therefore, if this hypothesis is to be further tested in the near future, it seems it will have to be done elsewhere than in New York.

The Committee on Administrative Practice of this Association is interested in obtaining further data that will tend

either to support or refute this hypothesis. It is hoped that every county and city health department in the country will secure and maintain such records as will enable it to determine where it stands relative to diphtheria immunizations now and at any time in the future. If diphtheria becomes prevalent there should be available not only a record of the cases, but a record by age of the children who have had a full series of toxoid or toxin-antitoxin.

A health officer's duty is first of all to his community—as a community. He must consider his people and their diseases in the mass and be concerned with the individual primarily as he affects the mass.

If the injection of 80 per cent or even 100 per cent of the older children fails to stop diphtheria in the community,

the project has failed. It is not important that he has stopped the disease among school children; it is not important that every one of those injected has been Schick-tested and found negative. But it is important whether or not diphtheria continues to take its toll among the unprotected.

If injecting 30 per cent or more of the under-5 age group will stop diphtheria among all groups, that is the essential thing to do. If it is not true, we should find it out without delay. If it is only partly true we should find out what the modifying factors are. If it is true we should know it with certainty.

We will not be able to determine the point until we have available for study reasonably complete and reasonably accurate records of immunization.

Inaugural Address*

J. L. POMEROY, M.D., F.A.P.H.A.

*Los Angeles County Health Officer; President, Western Branch,
American Public Health Association*

Mr. President, Honored Guests, Ladies and Gentlemen:

IT is indeed a great honor to be elected president of the lusty adolescent known as the Western Branch of our great American Public Health Association. It gives me great pleasure to accept this honor and I trust that I may be able to fulfil the obligations resting upon me in a satisfactory manner. Certainly it is important that those of us engaged in public health work in the western section of the North American Continent should have opportunity for exchange of views by coming together in an annual convention. Through such intercourse and exchange of ideas come much good and I sincerely hope that the future will show the steady growth in our development. The sympathetic and helpful attitude of the officers of our parent organization is stimulating and encouraging.

In reflecting upon the various points of view and attitudes of mind concerning our field of work an interesting if somewhat fantastic interpretation has occurred to me. During recent years I have been wont to look upon ourselves as workers on the great highways of life. Road building you know is an ancient and honorable profession. The old Roman Road of England is pointed to today with great interest. Road building requires a number of operations. The selection of a proper route,

the planning of the highway, the drawing of specifications and finally actual building operations. It is important that along the highway there shall be signs directing the traveler and warnings against dangerous detours. Maintenance and repair are also of great importance; and perhaps most important of all came into being the "bridge builder."

The great field of public health has many similar analogies to the profession of road building. There must be those who go ahead and blaze the trail, charting the way in the great unknown. Some work in the field of research studying better methods and solving the vexing problem of frequent defeats and analyzing our failures. Some are engaged in health education and place the sign boards along the highway of life. Many are engaged in what might be called maintenance and repair work. It is indeed true that there are many dangerous detours and bypaths tended by quacks, pretenders and cultists of many kinds, constantly seeking to lead the public from the safe and sane highway.

But whether we are engaged in the major work of planning or whether our walks are in the humbler paths, each group of workers in the field of public health plays a most important function not only in providing safe and sane highways but in keeping these roads clear of danger and swift of travel.

These thoughts have been suggested by an anonymous poem as follows:

* Read before the Fourth Annual Meeting of the Western Branch of the American Public Health Association, Pasadena, Calif., May 30, 1933.

THE BRIDGE BUILDER

An old man, traveling a lone highway,
 Came at the evening, cold and gray,
 To a chasm vast and deep and wide.
 The old man crossed in the twilight dim,
 The sullen stream had no fear for him;
 But he turned when safe on the other
 side,
 And built a bridge to span the tide.

"Old man," said a fellow pilgrim near,
 "You are wasting your strength with build-
 ing here,
 Your journey will end with the ending
 day,
 You never again will pass this way.
 You have crossed the chasm dark and
 wide;
 Why build you this bridge at eventide?"

The builder lifted his old gray head:
 "Good friend, in this way I have come,"
 he said,
 "There followeth after me today
 A youth whose feet must pass this way;
 This chasm that has been as naught to
 me
 To that fair haired youth may a pitfall
 be.
 He, too, must cross in the twilight dim,
 Good friend, I am building this bridge
 for him."

Looking backward we might well re-
 view some of the great pioneers who
 might be termed "bridge builders." Perhaps one of the most important of these was Florence Nightingale, that angel of mercy and cleanliness in the hospital. During the Crimean War at the barrack hospital at Scutari she demonstrated the great need for fresh air, cleanliness, and trained attendants in the care of the sick. She laid the foundation for the modern trained nurse. Next came the work of Louis Pasteur and his immediate followers who bridged the great chasm of darkness and death in relation to bacteriology. Joseph Lister in 1867 showed that infection in wounds could be prevented by antiseptics and by cleanliness, and the advent of surgical cleanliness, the supreme virtue of modern hospitals, dates from his time.

Perhaps that greatest and most appalling "grand canyon" of death, tuberculosis, might be said to have been spanned by Robert Koch and his followers in Germany through the discovery of the tubercle bacillus and its relationship to infection. In the conquest of diphtheria, special pathways and bridges for the feet of little children were laid down by Behring, Roux, Park, Schick and many others.

We cannot fail to mention with considerable pride our own Oliver Wendell Holmes, who even prior to the demonstration by Semmelweiss, suggested that puerperal fever was a true infectious disease. This discovery lifted a tremendous burden from the women of mankind and might truly be said to make up one of the most important bridges on the pathways of life. In that great field of prevention of infection, the introduction by Jenner of vaccination against smallpox certainly must be mentioned as the laying of foundation stones. The very basis of all our modern work in immunology rests upon this noble experiment.

The pioneer work of Laveran with malaria, together with the work of Ross and finally our own Americans, Walter Reed and his associates at Havana, opened up the pathway of safety in dealing with disease carried by mosquitoes and insects. In this connection we must mention the name of another American, that of Ricketts, whose fundamental demonstration on ticks in the transmission of rocky mountain fever was of supreme importance in the west. It is romantic indeed to think that even the humble, obscure and remote pathways from the mountains in Montana to the jungles of Africa, can and shall be made safe through preventive medicine for those who tend the sheep and herd the cattle. How truly democratic is the field of preventive medicine which makes smooth the way not only for those in high places who

travel on the broad highways, but yea, even for those whose walks lead in the humbler and simpler bypaths of life.

In the field of intestinal parasites the names of those workers who have driven many rivets in these life-saving structures are too numerous to mention in detail. Perhaps most fundamental are the development of water supply purification methods, improvements in disposal of sewage, together with the clinical work on typhoid by Budd and others.

The early history of sanitation is closely linked with the names of Sedgwick, Burdon-Sanderson, and Kirkwood. Likewise the development of chlorine treatment of water by De Morveau of France and Cruickshank of England, together with the work of George W. Fuller in America, deserves special mention. The first steps taken by Wyatt Johnston, of Montreal, were the beginning which culminated in the development of standard methods of water analysis.

Closely connected with this subject of bridge building is the solving of problems related to the development of children in this country. The work of Holt, Jacobi and Josephine Baker on the clinical side, together with modern development of milk production and pasteurization can truly be said to have been epoch making. More lately the growth of our knowledge concerning vitamins, the refrigeration and handling of foods, have cleared many of the obscure and dangerous pathways for childhood and motherhood. Perhaps nothing is more fundamental to the health of mankind today than the development of means of purification of milk for human consumption, modern refrigeration and modern canning methods. In our southern states we cannot fail to mention the remarkable lifegiving work done by a host of

workers in the United States Public Health Service in dealing with hookworm, malaria, pellagra and many other diseases.

But our bridge builders have not alone been bacteriologists, chemists and research men! These men might be likened to those who test the factors of safety in our health construction work and point the way to methods, but after all the health administrator is the engineer who actually superintends construction. The names of Stephen Smith, Hermann Biggs, George M. Sternberg, William Gorgas, and to bring home to those of us in Southern California, L. M. Powers of Los Angeles, Stanley Black of Pasadena, and Fitch C. E. Mattison of Pasadena, are dear to our hearts. In this brief sketch let us take courage that even those of us who simply patch the worn places in the highways, and yes, those of us who are merely throwing hot rivets to the man higher up to ram home in this great structure, the bridge of life,—we too serve a fundamental purpose. After all, the fate of a nation rests upon the health of its individual citizens. The health officer who applies to the best of his ability modern preventive medicine in town and village carries the fate of the nation in his hands. Let us each therefore do his best to smooth the pathways, be they ever so humble, because after all without the pathways and secondary roads there can be no greater highway of life.

And so when the end comes and the Greatest Engineer of all lifts the draw bridge, may we pass into that final canyon which science perhaps never can successfully bridge with the consoling thought that we have done everything possible for our fellowman in rendering a service to help make the way safe for those who follow after us along the great highways of life!

The Training of Health Personnel*

W. S. LEATHERS, M.D., F.A.P.H.A., AND A. E. KELLER, M.D.

*Department of Preventive Medicine and Public Health, Vanderbilt
University School of Medicine, Nashville, Tenn.*

THERE is perhaps no problem confronting the public health authorities of the United States of greater importance than to provide qualified health personnel. The development of county health work on a full-time basis is one of the great modern achievements in public health. Since the first full-time health unit was established in Yakima County, Wash., in 1911, this type of health organization has been carefully scrutinized, and based upon the results accomplished it has passed the experimental stage. At the close of 1931 there were 596 full-time county or district health organizations in 36 states. A large proportion of these have been established in southern United States, but it should be emphasized that such health demonstration centers are found at present in all sections of the country. As a result of this extension in health service and other factors, such as the expansion of state health departments and improvement in municipal health services, the demand for adequately trained personnel in this field has exceeded the supply. This problem has also become more acute because of the need for well prepared and experienced workers by voluntary health agencies.

It has been estimated that for each rural population unit of 20,000, theoretically, there should be 5 trained health workers, consisting of a health

officer, nurses, and sanitary inspectors, properly to meet the expected demand; and also that it will require as many as 300 physicians a year to supply the demand of health agencies.

The most deterring factors in securing trained personnel from among physicians are the probably inadequate educational facilities for teaching public health and preventive medicine in our medical schools. A large per cent of the health officers in this country should be graduates of medicine, but unless medical students are taught in a comparable way the preventive aspects of medicine it is not probable that the promising graduates of medicine will become interested in sufficient numbers to adopt public health as a career. A careful analysis of the facilities for teaching preventive medicine and public health to medical students has been made, and of the 60 medical schools included in this analysis only about 12 use facilities and employ methods for teaching this subject in a manner comparable with those for such subjects as anatomy, physiology, medicine, and surgery. The instruction in the remainder appears to be unsystematic and poorly organized. This phase of teaching seems to have received less attention than many subjects of relatively minor importance in the medical curriculum. In only a small number of schools does it seem that a broad concept of public health is developed or that the subject is being treated in a manner commensurate with

* Read before the Fourth Annual Meeting of the Western Branch of the American Public Health Association, Pasadena, Calif., May 29-31, 1933.

its far-reaching importance. The frequent combination of preventive medicine and public health with departments of bacteriology and even pathology does not seem logical or sound from the pedagogic point of view, since a modern public health program is a dynamic function more closely related to the clinical branches of medical science. We wish, therefore, to stress the defect which exists today in this respect in teaching medical students and the serious consequences which will follow because of their lack of understanding of the principles of preventive medicine and the trends in the field of public health. Obviously, in considering the problem of the training of health personnel a fundamental need is to provide better facilities for teaching the undergraduate medical student the principles of public health. This would place him in a position to more successfully use his knowledge concerning the prevention and control of disease in general practice.

It is generally agreed that one of the great needs in public health education in this country is to supply trained personnel for local or county health departments. There is urgent need at the present time in different sections of the country for graduate courses in public health which will provide fundamental training and afford opportunity for experience in the field for those seeking positions in public health. There are approximately 3,079 counties in the United States. The ideal would be to have all of these counties individually or in groups organized on a full-time basis. It is, therefore, evident that some plan must be worked out by which more adequately trained personnel can be provided for the relatively smaller units of health organization. Such a plan should also provide opportunity for "refresher" courses with reasonable regularity.

This can probably best be accom-

plished by better utilizing the facilities in certain universities for training health personnel. From the point of view of convenience, economy, and stabilization of local health service, the establishment of graduate courses of instruction in certain medical schools, or graduate schools in coöperation with state and local health departments would contribute largely toward supplying this demand. We must not overlook the important fact that the health officer of the county becomes a general practitioner in the field of public health and consequently he cannot specialize in any one branch of preventive medicine.

There are as many as 5 groups of medical men who apply for positions as county health officers: (1) the recent graduate who is interested in a salaried position merely in order to save sufficient money to establish himself in practice; (2) the physician who has spent several rather unsuccessful years in practice and is desirous of making a change; (3) the practicing physician who has been fairly successful, but on account of the strenuous activities associated with practice is desirous of taking up public health work, being under the impression that he will be relieved of much of the stress and hardship incident to private practice; (4) the physician who has been successful in practice and who goes into public health because he has obtained from association with public health officials and from seeing the needs of his community an insight into this new field of medical activity and its possibility for service; (5) the young graduate in medicine who has had instruction in preventive medicine and who has a real interest in following public health as a career. At present there are not enough men in the last 2 groups entering the field.

Until within recent years the field of experience was the only school in which

most physicians gained their knowledge concerning public health procedure. While this has been necessary in the past, owing to a lack of facilities for adequate instruction, it should no longer be encouraged. The development of public health in the past 15 or 20 years has been so rapid that it is hazardous to place wholly untrained persons in the field.

In October, 1922, the International Health Division of the Rockefeller Foundation in conjunction with the State Health Department of Alabama established a field training station at Andalusia. The plan followed in this station was to place the candidate in the field immediately upon his arrival. Obviously, all the training was practical. He was associated in the field with some member of the county health department. The actual experience which the person obtained depended upon the amount of time he could remain at the station. If he remained long enough he would be assigned definite tasks or be given a field problem to study. All of his work was supervised and planned as far as possible by the director of the station. Those in training were also instructed concerning methods of handling reports, filing records, and given some idea with reference to the details of administration. Conferences were held on one afternoon a week to plan the work for the coming week. Usually some public health problem was discussed by the director of the county unit or by some member of the staff of the state health department. The primary purpose of the training station was to provide field experience and appraisal for newly appointed members of the staff of the International Health Division in preparation for the responsibilities of foreign service, and also to aid state health organizations in this respect. The two great schools of public health had just been established and

there was certainly a definite need for field stations for determining the suitability of persons for public health work.

Following the opening of this station two others of a similar nature were started, one in Mississippi and another in Ohio. Somewhat more recently a fourth training base was established in Michigan in connection with the state health department. These training stations represented an attempt to train health personnel by a more or less intensive field method. During the first 5 years 283 physicians were enrolled. Of those trained during this period in Alabama 13.6 per cent did not receive the approval of the director. These stations served a valuable purpose. This method of training health personnel has stimulated interest concerning the need. Such training stations have been discontinued. There are, however, a few states which are endeavoring to provide limited field experience for new appointees before entering upon their work.

Since the problem of training health personnel is one that confronts each state health organization, there may be some value in recounting the essential advantages and disadvantages of the field training station.

To enumerate the advantages:

1. Physicians who would probably have gone into some other field of medicine may be induced to enter upon public health work.
2. These stations have also served to awaken an interest and enthusiasm in public health and have given to those undergoing training a better conception of the scope of preventive medicine.
3. The individual has obtained a better idea of the relative values of the various public health procedures.
4. It has been a means for giving physicians who were interested in going into public health as a career an opportunity to determine whether or not they were adapted to this phase of medical service.

What are the disadvantages of the field training station?

1. These stations have been placed in rural counties where there is a representative health organization usually consisting of a 4-person health department, and the lack of personnel for proper supervision and teaching has been a handicap to efficient instruction.

2. It is practically impossible to carry on a balanced county health program and at the same time assume considerable responsibility for teaching unless additional personnel is provided.

3. A lack of transportation facilities is also a serious handicap.

4. Many of those who register for training are physicians who have been out of college a number of years and but little opportunity is afforded to review the fundamentals of preventive medicine and public health.

5. The kind of training received depends upon the time of the year and also the activities in progress at the time the physician comes for training.

6. No definite systematic instruction in the sense that it is given in a university is attempted. An effort is made to teach and to show what is meant by a balanced county program, but even though this is attempted the time is inadequate to give one the essential knowledge for outlining a program in carrying on county health work. These disadvantages seem to confirm the idea that a more intensive and thorough preparation is required.

During the past decade or so courses of instruction in public health have been given in various ways. They have ranged from so-called institutes of a few days' duration to a full course leading to a degree of Doctor of Public Health. All agree that something more than a didactic course is necessary to prepare a man for a career in public health. Any plan of instruction should include a limited supervised field experience. The principles employed in actual practice must be stressed.

To carry out such an idea would necessitate coöperation between educational institutions and administrative health agencies. Such an arrangement is necessary in order that proper standards and methods of instruction be developed and maintained. We are, therefore, of the opinion that courses in public health should be organized in a

few universities representing different sections of the United States so that systematic instruction is made more available to those who may wish to enter upon public health. It is well to remember that the undergraduate student of medicine today is a graduate of an accredited high school; he must have had not less than 2 years of college work, and a large number of candidates for the degree of Doctor of Medicine have obtained the bachelor's degree; added to this is 4 years in a medical school and then from 1 to 3 years of internship before entering upon his career, whether it be in general practice or public health. Those who desire to specialize in some phase of public health may in addition devote from 2 to 3 years to study further in a school of public health. However, experience shows that in this transitional period in public health development in the United States it is necessary to afford opportunity for physicians and other types of personnel to secure more limited courses of intensive training in the state, or at least in the section of the country, in which these persons wish to engage in public health work.

It is for this reason that we have attempted to develop a postgraduate (graduate) course in public health in Vanderbilt University in coöperation with the Tennessee State Department of Public Health. By such an arrangement the resources of a teaching institution can be coöordinated with the health department. The teaching force is drawn from the Vanderbilt University School of Medicine, the Tennessee State Department of Public Health, and the local health departments. This course has been established on a satisfactory basis and has been given at reasonably regular intervals since 1928. The primary purpose of the course is to fit graduates of medicine for positions as county health officers. It is intended to be an introduction to the subject; to

give the physician a working knowledge of public health; and to give him a better foundation upon which to build. Two main objectives are recognized: (1) to acquaint the medical graduate with the field of public health, its possibilities, its problems, and methods of work; (2) to develop the point of view of the health officer. This course affords an opportunity to review certain fundamentals and at the same time give considerable attention to the administrative side of public health. During this period instructors are able to estimate a physician's potentialities as a county health officer.

The completion of the postgraduate course offered requires 12 weeks, divided into 2 periods of 6 weeks each. The first period consists of lectures, demonstrations, laboratory work and group conferences. It has been found necessary to give some clinical instruction. This is important because it is desirable for a local health officer to know not only preventive medicine and public health but also clinical medicine, at least to the extent of being acquainted with diagnostic methods, particularly in the field of acute communicable diseases. The second period is actually devoted to field work in a well-organized local or county health department. During this period the men in training enter into the regular work of a county health department. In doing so they follow a definite schedule and record their observations. Each man or group of men is given a special problem to study. This usually consists of a sanitary survey of some small town or community. Seminars are held at regular intervals and at the end of the course opportunity is afforded for a discussion of the results of the special assignments. The completion of a course of this kind, or evidence of equivalent instruction and experience, is required by the Tennessee State Department of Public Health for employment as director of a

full-time county or district health department.

During the course approximately 500 hours are devoted to intramural and extramural instruction. The following table will give an idea of how the time is divided.

NUMBER OF HOURS OF INSTRUCTION

FIRST PERIOD—INTRAMURAL (CLASSROOM)

| <i>Subject</i> | <i>Number of Hours</i> |
|---|----------------------------|
| Public Health Administration (General) | 81 |
| Communicable Disease Control | 48 |
| Sanitation | 37 |
| Epidemiology | 15 |
| Vital Statistics | 22 |
| Maternal and Child Hygiene | 15 |
| Medical Zoölogy | 12 |
| Public Health Laboratory | 9 |
| Industrial Hygiene | 7 |
| Mental Hygiene | 3 |
| | <hr/> 249 |

SECOND PERIOD—EXTRAMURAL (FIELD)

| | |
|---------------------------|-------|
| County Health Departments | 192 |
| Sanitary Survey | 38 |
| | <hr/> |
| Total | 479 |

The most important branches of preventive medicine and public health are emphasized.

From personal experience with those who have registered for instruction in these courses, one is led to conclude that the training which each man received has been a factor in his success. Of the men who have taken these courses (more than fifty), all except 3 have continued in public health. They have been particularly successful in retaining the appropriations for the work, even under the present economic conditions. In fact, in some of the counties the appropriation has been increased. The indications are that this plan of training has proved of definite value and has made a contribution in providing better trained health per-

sonnel. We are well aware of the fact that such a course can only be considered as an introduction to public health from the standpoint of specialization. If given for a period of not less than 5 months or possibly a year it would be more satisfactory.

The training of personnel for public health work must be stimulated by the official administrative health agency of each state. However, based on our experience in Tennessee it would be unwise and indeed impracticable for a state health department to develop a plan for training health personnel without the coöperation of an educational institution which has the facilities to undertake this task. On the other hand, it would also be unwise and unreasonable for a medical school or university to assume responsibility without the coöperation of state and local health organizations. It is, therefore, necessary to have a coöperative arrangement between the agencies which will provide the faculty and facilities for systematic instruction in the class room, laboratory, and clinic, and also to have supervision in field work by the staff of a well-organized county health department. In offering postgraduate (graduate) instruction to health officers it has been my experience that the major responsibility in providing the curriculum and facilities for teaching should be assumed by a department of preventive medicine and public health of a medical school or possibly graduate school. This is to stress the point of view that in giving courses of instruction the university is the logical place in which to head up such an organization and it should assume definite responsibility for administering a course of this kind in coöperation with state and local health organizations. The state health department can perform well the following functions in such a plan: (1) develop an appreciation of the need for training health personnel; (2) assist in mak-

ing arrangements for such training; (3) provide the facilities for field work; (4) insure high professional standards on entering upon health work.

We have referred especially to the instruction of those who may be chosen for health officers. We wish now to give brief consideration to the training of sanitary inspectors. This has been a serious problem to the administrator of state and local health departments. Much of the success of a local health unit depends upon the type of sanitary inspector employed. In most places at present the inspector receives no preliminary training before being placed in the field. He is often chosen on a political basis. Many have had but little educational opportunity. Obviously better provision should be made for the preparation of this type of personnel.

In an endeavor to improve this situation, the State Health Department of Tennessee has worked out a plan for training sanitary inspectors in coöperation with the State University in Knoxville. The requirements for entrance into this course are the same as for entrance into the university. The applicants are recommended by a representative of the State Health Department subject to the approval of the committee on admissions of the state university.

The course, as given at the present time, extends over a period of 15 weeks, 13 of which are spent at the University of Tennessee and in the Health Department of the City of Knoxville, the other two in a rural county health unit. The course is divided into 2 parts, (1) didactic, consisting of 160 hours; (2) field work, consisting of 420 hours not including the 2 weeks with the county health unit. This course attempts to teach the fundamental subjects connected with sanitation and at the same time gives the point of view which a sanitary inspector should have. The

following phases of sanitation are covered:

1. Sewage disposal
2. Water supplies
3. Mosquito control
4. Milk sanitation
5. Control of communicable diseases
6. Practical demonstration in bacteriology
7. Refuse disposal
8. Rodent, insect and vermin control
9. School sanitation
10. Statistics.

Most of the men who have completed this course are now in the employ of the state or county health departments. Doctor Wilhelm has made the following statement in regard to the results obtained.

In the beginning the Tennessee State Department of Health and the University of Tennessee felt it was a new departure and entirely experimental, but after completing 4 classes and experiencing the type of work these men have done with the county health units to which they have been attached, these institutions feel that it is a sound way to train sanitary assistants and feel well repaid for the effort put forth.

The other type of health personnel which should be given consideration is the public health nurse. An effort is now being made in Vanderbilt University as well as other institutions to teach the undergraduate nurse the principles of prevention in the undergraduate curriculum just as is being done in a number of schools in the instruction of medical students. In this way the student nurse should have a fair knowledge of hygiene and preventive medicine prior to entering upon special courses required for training in public health. It is imperative that the preventive point of view be emphasized throughout the curriculum of the undergraduate nurse and that she be made to realize her responsibility in the promotion of individual and community health. During the past decade or so special courses have been offered in a

number of institutions for the training of public health nurses which include theoretical instruction, laboratory work, and to some extent field demonstrations. Within recent years there is obviously a growing interest to establish field training for public health nurses as a part of their instruction both in the undergraduate and graduate curriculum.

The nurse fills an important place in the scheme of public health and too little attention has been given to the preparation of nurses who wish to enter public health work. In the School of Nursing of Vanderbilt University a course has been provided for training public health nurses, including such subjects as public health administration, the control of communicable diseases, prenatal and infant hygiene, school hygiene, mental hygiene, dietetics, and other phases of medical and public health service which are needed by a public health nurse in carrying out her part of the program in a public health organization.

During the early period in the development of public health in this country it was exceedingly difficult to secure trained personnel. It has been necessary frequently to follow a course in selecting personnel which could not be regarded as altogether satisfactory. Public Health has, however, passed the experimental stage and we have now entered upon an era which demands trained personnel. Public health has become a specialized phase of medical service requiring trained health officers, trained public health nurses, trained inspectors, trained sanitary engineers, and well selected subordinate personnel for clerical duties.

Opportunity is afforded now for one to get special preparation in 2 great schools of public health, Johns Hopkins and Harvard Universities. Graduate courses are being offered higher degrees also in several other institutions. However, there is as yet an insufficient

emphasis placed upon postgraduate instruction of a university type for those who wish to gain fundamental training before entering upon public health. This need not be so extensive and intensive as may be desired by those who wish to follow the more specialized phases of public health.

As has already been emphasized, local full-time health department personnel should be trained as practitioners of public health, and at least in this stage of public health development in the United States we cannot expect, nor should we require, that physicians who may wish to become health officers devote as much as 2 years in preparation for such service. We are endeavoring to differentiate between the individual who assumes responsibility as a general practitioner of public health and one who may wish to specialize in some field of public health service. The ideal plan would be for every one to receive specialized training at least from a theoretical standpoint, but we are confronted with a practical situation which must be dealt with in a reasonable and judicious manner. It is for this reason that emphasis is being placed upon the

need for a type of instruction which will provide a more efficient health personnel in meeting present demands with the hope that the qualifications, certification and licensure of health personnel in the United States will in the near future be more definitely established.

The progress of public health work will depend in a large measure upon the type of personnel selected for such service and this will also be an important factor in stabilizing public health organizations. There has been remarkable development within the past decade or so in providing facilities for public health work, but the facilities for training health personnel have not been made available in different sections of the country so that those who may wish to enter upon public health as a career can gain the instruction and practical experience which is needed. This is a need that should be supplied.

The Relationship of Public Health to the Doctor in Private Practice*

CHARLES W. DECKER, M.D.

Health Officer of the City of Los Angeles, Calif., one time Col. M. C., U. S. Army; Instructor in Military Surgery, Medical School, University of Southern California, etc.

THIS has been more or less a controversial subject for many years. Every period of depression stimulates its discussion. The prolonged economic depression now prevailing has acutely accentuated this problem, for physicians are unable to collect fees from patients who have no money.

Public Health as a field of medical endeavor is of comparative recent development. In 1864 New York City appointed saloon keepers and ward heelers custodians of public health as political rewards, and the service rendered was what one would expect from such personnel. The day has passed when a drygoods clerk or a bright young man from a banking house is considered capable of handling problems of public health.

Health officers themselves have not been blameless in delaying a better understanding of their relationship to general medicine. We can all recall the type of health officer, who, like the Pharisee, when he thanked God he was not as other men were, thanked God he was not as other doctors were. Only by recognizing that public health is a field of special practice of preventive medicine as distinctively a specialty as

surgery, otology, or ophthalmology, can we probably orient ourselves in the general group of scientific organized medicine.

The curative field of medical endeavor reaches back into the earliest historical records of man. The hieroglyphics of the Egyptians and the clay tablets of the Babylonians contain descriptions of therapeutic practice of their day. Public health is comparatively of so recent origin, that its very newness has resulted in diversity of expression regarding its purposes and even the ethics of its aspirations.

It was but natural that with the dawning of community consciousness of public health responsibility, the most available personnel should have been utilized to carry on the not too well understood sanitary program. Quite generally throughout the East the City Poor Doctor readily stepped into service as the health officer. In our newer Western communities, medical care of the indigent sick grew up with public health, and little if any segregation has ever been made of personnel engaged in the preventive practice of public health, and those in purely curative medicine.

School health and development work is often criticized as an additional burden that public health puts upon the tax payer. This is an unfortunate mis-

* Read before the Fourth Annual Meeting of the Western Branch of the American Public Health Association, Pasadena, Calif., May 30, 1933.

conception of what school health and development really is. It should more properly be designated as corrective physical education. The child with a visual or auditory defect, damaged heart, neurological impairment or deformity needs the care and guidance of skilled physicians, who are at once medical specialists and trained educators. The physically handicapped child requires this expert supervision if it is to develop into a useful citizen, instead of a charge later upon its family or public charity. The budget for corrective physical education should no more be charged as public health expense than any other part of the curriculum.

When declaration is made that public health should concern itself strictly with control of communicable disease, leaving therapeutics to private practice or welfare clinics, there are those who feel that all romance and interest would be removed from public health work. Glorious as have been the discoveries of curative medicine in alleviating the sufferings of mankind, equally glorious and romantic have been the sacrifices of our army medical and public health officers, who with their lives paid for the knowledge that now gives us control of yellow fever, malaria, typhus and Rocky Mountain spotted fever.

In California, statute law specifically designates counties as responsible for welfare,—food and shelter and medical care of the indigent sick. Such being the law, our City Attorney has expressed the legal opinion that we may no longer expend funds of our public health budget upon welfare. The Los Angeles County Welfare Department has some 17 million dollars in its budget, entirely separate and apart from County Public Health, and can properly provide required care. When public health can eliminate entirely

curative practice, excepting only treatment of indigent sufferers from communicable disease, from its field of labor, it will be relieved of the most frequent cause of criticism from the physician engaged in private practice. Doctors, and not infrequently the medical societies, complain that public health physicians immunize and vaccinate children to the detriment of the private physician's income. Public health can not abdicate its responsibility to safeguard the health of the community. We can, however, meet the criticism by agreeing to discontinue our immunization and vaccination services, when and to the degree that the private physician accepts his responsibility by doing this preventive work. We should place the baby requiring immunization in the private physician's lap, with the observation that we were but its guardians, and gladly restore it to its natural parents. Every doctor has a degree of responsibility in protecting the public health, and when he recognizes this, we will have more money and personnel to devote to sanitary services outside his field of activities.

It has been the endeavor of the Los Angeles City Health Department to cultivate friendly understanding with organized medicine as represented by our County Medical Association. This has happily been accomplished and at our request the Board of Councilors of the Los Angeles County Medical Association have constituted their Public Health and Public Relations Committee the Medical Advisory Board to the Health Officer. With such an intimate affiliation between public health and organized scientific medicine there can be built up in years to come an ever better, happier and more useful public health service, recognized, as it should be, as an ethical specialty in the broad field of medical practice.

THE INDIANAPOLIS MEETING

WE have just sent out a News Letter containing the call for the meeting of our Association in Indianapolis, October 9-12, to which more than usual interest attaches. We met there last in October, 1900, and it was there that Walter Reed, Chairman of the Army Commission sent to Cuba, to study yellow fever, made the first announcement of his success in transmitting the disease by the mosquito now known as the *Aedes aegypti*. That meeting is rightly considered one of the most notable in the history of our Association. While every member of the Commission is now dead, a few of those who took part, almost all as volunteers, are still living, and we are making every effort to have some of them present at the meeting. This demonstration of Reed and the Commission has been justly described as the most important contribution to science ever made by an Army surgeon, and as being second only to anaesthesia in its benefits to the human race. To this opinion we heartily subscribe.

It is proposed to have a special session devoted to yellow fever in which the part the Army Commission played will be discussed, and the Surgeon General of the Army has been invited to give the leading address on this occasion, and it is our firm opinion that he is the proper person to do this. Unfortunately, one or two of those who took part in these experiments, who are still living, through the infirmities of age and disease will be unable to be with us, but in spite of this, their names will be mentioned and due honor paid their courage and self-sacrifice.

As far as this country goes, yellow fever is a disease which has been confined practically to our southern states, in spite of the terrible epidemic of 1793 in Philadelphia, and some outbreaks even farther north. It is hoped that this fact will not lessen the interest of those from Canada and our northern states. There

can be no question that the studies conducted by Reed have not only cleared up the situation in regard to yellow fever, and saved thousands of lives, as well as millions of dollars through the opening of ports which were previously closed from spring until a killing frost in the fall, but have also been fertile in bringing about methods of study and researches which have had a far-reaching influence.

Yellow fever, from being the greatest menace of the tropics to our country, now occupies an almost negligible position, and never again will North America suffer an epidemic. Further than this, the studies carried out in Africa under the Rockefeller Foundation have added much to our knowledge, so that this disease, which was so mysterious even within the memory of most of us, is now an open book, and we are well on the road to the discovery of a practical vaccine by which non-immunes may be protected. There is no place in medical science for local or even national prejudices, and the same is true of science in general, though illness and death bring nations even more closely together than any other factor.

For many of us, a visit to Indianapolis will bring back delightful memories of Dr. John N. Hurty, for so many years the genial and efficient Health Officer of the State of Indiana. He was our host in 1900, and only to our younger members is it necessary to say that he embodied all that is best in what is implied in the word "host." Dr. Hurty was more than a health officer. He was a poet and philosopher. On another page (796) we give one of his poems which has been circulated far and wide, and has done an enormous amount to make people realize what preventive medicine and public health mean.

This issue of our Journal has the usual information concerning routes of travel by train, automobile or airplane, and it is only necessary to emphasize the unusual features of the meeting in Indianapolis, and to urge as large an attendance as possible, if for no other reason than to honor those who have done so much for humanity as well as for commerce.

CHARLES PORTER, M.D.

THE many friends of Dr. Porter among the membership of the American Public Health Association, of which he is an Honorary Member, will be delighted to know that he has been unanimously elected President of the Society of Medical Officers of Health of England. The apparent delay in giving him this honor was due entirely to his modesty, since for some 10 years he has been repeatedly nominated, and has as often withdrawn his name in favor of some colleague. This year, four nominations were made, but the other three withdrew in favor of Dr. Porter. He will assume office on October 1.

Dr. Porter is so well known that it seems unnecessary to give a list of the degrees and honors which he holds. It is suitable to mention, however, that in addition to his medical degrees, he is also a Barrister-at-Law, and holds the office of Medical Officer of Health of St. Marylebone, London. His other qualifications may be found in Who's Who.

He has held many positions of honor in the various associations with which he is connected, and has had a large experience as a lecturer and teacher, as well as an adviser in outlining studies in hygiene for other universities, and also on

examining boards, such as that for the Royal Sanitary Institute and Sanitary Inspectors' Joint Examination Board. He has been a prolific contributor to various journals on public health and, for a number of years, has been Honorary Editor of *Public Health*, the official organ of the Society of Medical Officers of Health of England.

Those readers who have not had the pleasure of meeting him—for indeed his visits to this country have been entirely too few—will recognize his letters in our Journal. At our Montreal meeting, at his suggestion, an arrangement was made by which he contributes to our Journal, and the editor of our Journal contributes to *Public Health*. The section of *Public Health* under the head of "Ut Ita Dicam" would alone make a man's reputation as a writer. Not only does it cover every item of interest in public health, but it is written with such a keen wit, tinged with a bit of cynicism, as to make it a delight to all. *Public Health* will continue to be edited in Dr. Porter's office at St. Marylebone, Dr. James Fenton, who has been associated with him in at least one publication, having been appointed editor.

In addition to Dr. Porter's articles for journals, the following publications are credited to him: Sanitary Law and Practice (Robertson and Porter); Sanitary Law (Porter and Fenton); School Hygiene and the Laws of Health; Elements of Hygiene and Public Health; The Future Citizen and His Mother; and the Parkin Prize Essay on Cholera.

Our readers will be glad to know that he does not look forward to discontinuing his letters. It is a peculiar pleasure to the editor of our Journal to be able to make this announcement authoritatively. His personality has made for Dr. Porter hosts of friends in every country where he is known, all of whom will take pleasure in knowing of the honor which he has at last accepted. This Journal adds its own congratulations and also felicitates the Society on obtaining his services as President.

EPIDEMIOLOGY AND AIR TRAVEL

WE have several times alluded to the problems connected with the transmission of infectious diseases from one country to another by the increase in air travel. It has long been recognized that as a rule contagious diseases travel at the same rate as means of human communication. For a long time infected man was considered perhaps the only danger, and the first international sanitary convention held concerned the prevention of the carriage of Asiatic cholera along caravan routes.

As early as 1585, we find that the City of Aberdeen took precautions "in case any infectit person might arrive or repair by sea or land to this brough," and erected gibbets for the punishment of those who harbored or even aided such persons. In 1663, Pepys tells of the arrival of plague at Amsterdam brought by a ship from Argier, and says that the King of England purposes to forbid Dutch ships from coming into the Thames. In those days of sailing vessels, practically all diseases which might have been carried by ships passed the period of quarantine (40 days) on the voyage. With the coming of steam, conditions were tremendously changed, and now again with airplanes, an entirely new problem is presented. Speed of transportation is, other things being equal, equivalent to reduction in distance.

The Health Organization of the League of Nations, the International Air Navigation Commission, and the International Hygiene Office in Paris have already had a number of meetings to consider the problems which have arisen. Reports have been made by several ministries of health, and measures have been taken by some countries against the exportation and importation of diseases by airplanes.

Some of the most interesting experiments have been done by the U. S. Public Health Service, which has shown that a number of mosquitoes, including some of those known to carry disease, may be transported easily from tropical countries to the United States, and also that occasionally these mosquitoes will bite human beings at an elevation of 3,000 feet. Not only have mosquitoes traveling by their own volition, so to speak, been found arriving in this country, but when stained mosquitoes are liberated in the cabins of airplanes, a considerable number of them survive the trip, and are found in good condition on arrival. There can be no question that other insects known as disease carriers can survive airplane travel in the same way, and theoretically, at least, some of them can find more comfortable quarters in planes than mosquitoes.

Among the infections which seem to be the greatest menace to the world are yellow fever, plague, Asiatic cholera, and smallpox. The incubation period of these diseases is respectively 6, 6, 5, and 14 days, while the airplane trip between the countries in which these diseases are endemic and England, for example, runs from 6 to 3 days. With constantly increasing speed and the likelihood that airplanes may soon fly through the stratosphere, where speeds will be still greater, the menace will be correspondingly increased.

Yellow fever is now known to be endemic on both the east and west coasts of Central America, the north and part of the east coast of South America, and a large part of the western coast of Africa. So far it has not been carried from west to east, for reasons which are not well understood, the vector mosquito seeming either unable or unwilling to make the trip. On the other hand, the potential geographical incidence of the *Aedes aegypti* includes parts of both coasts of North and South America, Africa, India, part of China, and the Straits Settlements, and the east coast of Australia. From what we know of the history and spread of malaria, there seems to be good reason to believe that should a case of yellow fever be carried into any of these areas, the disease could and probably would be propagated and possibly become endemic. When we think of the hundreds of millions in India, South China and the Straits Settlements among whom epidemics might occur, the possibilities are appalling.

Plague is indigenous in India. It has been said that this country is its natural home and habitat. It is constantly present in the South of China and some of the Straits Settlements, as well as in China. In the past, it has been repeatedly brought by ship and by caravan routes to the West. New relationships bring new responsibilities and new dangers. Becoming a world power has brought to the United States responsibilities and dangers which were never thought of only a few years ago. Trade must be carried on. So far we have been able to overcome the principal diseases found in the trade routes of the world, and there is little doubt that we will accomplish the same with respect to airplane travel. Until now the limitations and expense of traveling by airplane have been such as to limit the risks. Only the richer and better class of people, as a rule, travel by airplane. It would surprise no one, however, to see air travel become much cheaper through the introduction of planes which would carry 100 or more

passengers. Indeed, in the United States, along some routes travel by air is at present cheaper than by rail, when the cost of meals, parlor cars, etc., are taken into account.

We are entitled to a great degree of satisfaction in knowing that several leading countries, such as America, England, Germany, and France, are well aware of the problems and are actively studying them. The work of the Rockefeller Institute in developing a vaccine against yellow fever is also reassuring.

These and other problems are considered in a very timely volume,¹ which includes maps showing the distribution of several diseases and the habitat of carrier mosquitoes for them, and also measures which should be adopted against the transmission of these diseases by airplane. It is high time for us to go beyond regarding the airplane as a curiosity and a wonder, and to recognize that it has come to stay as a means of transportation.

Sixty-second Annual Meeting of the American Public Health
Association, Indianapolis, Ind., October 9-12, 1933,
Headquarters, Claypool Hotel

LETTER FROM GREAT BRITAIN

BRITAIN'S PREMIER HEALTH CONGRESS

The annual congress of the Royal Sanitary Institute—which, as I believe I have already mentioned, corresponds to the conference of the American Public Health Association—was held this year during the week June 17–24. This was somewhat earlier than usual on account of the fact mainly that the venue was Blackpool, a seaside health and pleasure resort and a popular “congress town” in the county of Lancashire, where the season is at its height in July, the usual meeting time, and in July accommodation for other than pleasure seekers is difficult to secure. For the reason that the Minister of Health had advised local health authorities that he would not approve the payment of the expenses of more than one delegate to this or any other conference, it was expected that the attendance would be much below that of previous years. Curiously, this was not the case, the official returns showing the actual number registered as 1,353, as against 1,389 in 1932. So far as health officers are concerned, the impression gained was that there was little or no falling off, all or nearly all of those one expected to meet being encountered here or there at functions or meetings. Of delegates from overseas there was a goodly number, including four representatives of the United States of America. Amongst these I was particularly pleased to find present, representing the Government, Dr. John McMullen, Medical Director in Supervisory Charge, European Activities, and stationed in Paris; and Dr. F. J. Halpin, Passed Assistant Surgeon, United States Public Health Service, now at the Consulate in London. As

this is some two blocks from this office we meet only at congresses held in the provinces. In addition to Dr. McMullen and Dr. Halpin, there attended from the United States of America a representative of the Massachusetts Department of Public Health, James L. Tighe, and Professor Felix d'Herelle of Yale University. Dr. Richard A. Bolt of Cleveland, Ohio, now in Europe studying maternity and child welfare provisions, in Germany particularly, under an award from the Oberlaender Trust, interrupted his enquiries in Berlin to attend the congress, and helped very greatly by taking part in several of the discussions. As he is attending also what is called—without, it would seem, much sense of euphony—“The Sixth English-speaking Conference on Maternity and Child Welfare,” which opens in London, and a pediatrics conference later, there will be further opportunities of seeing something of him. Amongst other countries sending delegates were China, Costa Rica, Egypt, Hungary, Iraq, and Italy. Some of these and others from overseas British dominions we had the pleasure of hearing at a luncheon given to overseas representatives, a function which is perhaps the most attractive of the several gatherings held during the week.

MATTERS OF MOMENT

Meetings during the course of the congress were very numerous, and a multitude of papers were read and discussed at the various sections and conferences. The attendances in certain cases were very large: at one section, for example, when housing questions were under consideration, over 400 were present. The Preventive Medicine and

the Maternity and Child Welfare Sections, always very popular, brought together at times about 300 people. At the former the two main subjects considered were "A General Medical Service for the Nation" and "Psychological Problems in Industry." The former is a question that is exercising many minds at the moment and has arisen, as it was bound to arise, out of the operation of the medical benefits under the National Health Insurance Acts. The British Medical Association has attempted to draft a scheme satisfactory both to the medical profession and the people. The section was fortunate in having Sir Henry Brackenbury, Chairman of Council of that body, as President, and Dr. Alfred Cox, formerly Secretary, as opener of the discussion. The general view expressed was favorable to the provision of a national service, and quite a number appeared to regard the British Medical Association scheme, as propounded by Dr. Cox, as suitable, or at any rate not unsuitable. The opening papers on "Psychological Problems in Industry" came from a professor of psychology (Prof. Pear, of Manchester University), the managing director of a large department store in Liverpool (F. G. Marquis, M.A., M.Sc., of Messrs. Lewis & Co.), and the medical officer (Dr. Leonard P. Lockhart) to the Boots Pure Drug Co. Talk on psychology and problems connected therewith can be immensely fascinating, and these three papers were very greatly to the liking of the listeners, though many did not seem to feel that they were able to do much about it when all the reading and discussing ended. Of the delegates, 2 or 3 hundred chose to attend the Maternity and Child Welfare Section instead of the Conferences of Medical Officers of Health, or Engineers or Surveyors or the Veterinary Hygiene or National Health Insurance Sections or the Section of Architecture, Town Planning and Engineering.

THE MATERNITY AND CHILD WELFARE CONFERENCE

The Maternity and Child Welfare Conference in London, to which reference has been made, now in its sixth year, is one of the events of National Baby Week which falls usually in the first week in July. Primarily the responsibility for the organization of the conference is on a voluntary body known as the National Association for the Prevention of Infant Mortality, though a large number of other bodies concerned in infant and child welfare take part also. The President on this occasion was Sir George Newman, of the Ministry of Health. Responsibility for each of the sessions is placed upon one of the organizing bodies, and as a result this year, as usual, a considerable variety of subjects passed under review. The scope and advancement of ante-natal care, for example; the care and protection of illegitimate children; work on behalf of crippled children; tuberculosis amongst children; and the diet of the child after the period of milk feeding—all of these subjects were opened by persons of repute, and, as the audiences were largely lay, considerable enthusiasm was shown and there was a deal of useful discussion. A feature of the meeting was a clinical course for medical practitioners, arranged partly by the Maternity and Child Welfare Group of the Society of Medical Officers of Health. This included visits to and demonstrations at various hospitals and institutions, and proved very attractive.

THE TRAINING OF THE NURSE FOR THE NURSERY

These had an opportunity of learning something of the need for and advantages of maternity hospitals or homes in connection with maternity and child welfare schemes, and of the propriety of providing special training and qualifications for girls desirous of

becoming nursery nurses and taking charge of other people's children. This is a question in which the Royal Sanitary Institute is particularly concerned, since one of its chief activities is the examination and certification of persons seeking to secure appointment as non-medical members of public health departments or in other positions where a knowledge of hygiene is a desideratum. It was because the Viscountess Erleigh has had this as one of her chief interests that she was chosen President of the section, and led off with an address that helped to cause the discussion to assume a very lively importance. After the case for maternity hospitals or homes had been completely proved, the section discussed the question of rheumatic infection in childhood, one which is giving rise to a considerable degree of anxiety at the moment and in regard to which many health and education authorities are desirous of obtaining guidance. In the course of the discussion many very interesting and useful views were expressed by persons engaged in an endeavor to deal with the problem, and it is possible to believe that as a result of this meeting a certain amount of advance in the direction of devising a suitable scheme was made.

The final subject on which pronouncements were made was the need for the establishment of orthodontic clinics as part of school medical treatment schemes. The time at disposal allowed for little more than the reading of a paper descriptive of what is claimed to be the first clinic in this country, but opportunity may be found later for further communications on the subject.

THE PRESIDENCY OF THE SOCIETY OF
MEDICAL OFFICERS OF HEALTH

The Society of Medical Officers of Health, in accordance with custom, towards the end of May selected its President for the next session. The rules provide that each Branch may nominate an individual, and on this occasion four names were put forward. Of the four, three most generously withdrew in favor of the fourth, and as he is an Honorary Fellow of the American Public Health Association he trusts it may be a source of gratification to those within the Fellowship of the Association to know that one of their number has had this distinction conferred upon him. His name is appended hereto.

ASSOCIATION NEWS

THE INDIANAPOLIS MEETING

WILLIAM F. KING, M.D.,

General Chairman of the Local Committee on Arrangements

BENJAMIN HARRISON, when President of the United States, in referring to Indianapolis, said, "I myself am a citizen of a no mean City."

Indianapolis is preparing to extend every possible courtesy to the American Public Health Association and will make every effort to have the 1933 meeting of the Association an outstanding success.

Trips will be arranged to the many places of interest in and about the City and special entertainment will be provided for women members and visitors.

For Sanitary Engineers there will be a trip to the Filtration Plant and Pumping Station of the Indianapolis Water Company and a visit to the Sewage Treatment and Disposal Plant of the Indianapolis Sanitary District. For Health Administrators a visit to the Indiana University Medical Center which includes the University School of Medicine, the University School of Dentistry, the Indianapolis City Hospital, Robert W. Long General Hospital, the Coleman Maternity Hospital and the Riley Memorial Hospital for

children. Of general interest will be visits to the International Motor Speedway; the World War Memorial; Lockerbie Street, the home of the Hoosier Poet, James Whitcomb Riley; Butler University; Garfield Park with its fountains and sunken gardens; Foster Hall, built by Mr. J. K. Lilly and dedicated to the memory of the greatest American song writer, Stephen J. Foster; the Laboratories and Biologic Farm of Eli Lilly and Company; the Scottish Rite Cathedral, said to be the finest Masonic Cathedral in the United States; the classic City Library and the newly erected State Library and historical building; the model kitchens of the Van Camp Company; the home of the Real Silk Hosiery; Indiana Soldiers

and Sailors Monument; Municipal Parks and Play Grounds and other distinctive places of interest.

For those who play golf, Indianapolis has to offer five municipal courses in addition to the splendid courses of the Country Club, Woodstock, Highland, Meridian Hills, Avalon and Arlington Clubs.

The Ladies' Auxiliary of the Marion County Medical Society is planning entertainment for women delegates and visitors to the Indianapolis Meeting. While the program of the meeting will be given first importance there will be no lack of opportunity for relaxation, recreation and special features.

Indianapolis will be at its best in October.

ANNUAL MEETING INFORMATION

CONTINUED FROM JULY ISSUE

Reduced Railroad Fares

REDUCED railroad fares on the Identification Certificate Plan have been authorized by the several passenger associations in the United States and Canada, which will entitle all members and dependent members of their families to a special rate of fare and one-third for the round trip to Indianapolis.

Under this plan an Identification Certificate *must be presented* to the ticket agent when purchasing tickets. (One will be mailed to every member of the Association on September 5.) This is the ticket agent's authority to issue to delegates and dependent members of their families a round-trip ticket to Indianapolis at the reduced rate. All return tickets must be validated, before leaving Indianapolis, at the regular railroad ticket office.

It is suggested that all members consult their local ticket agents in regard to dates of sale as they vary according to distance from Indianapolis. The

final return limit is 30 days in addition to date of sale. Delegates may travel to and from Indianapolis via the same route or via diverse routes, as they prefer, without additional cost.

Members who wish to include a visit to A Century of Progress in Chicago with their trip to the Annual Meeting should consult their local ticket agents as to the best route and the most favorable rates. In some cases, the World's Fair rate granted by the railroads is lower than the convention fare. Ticket agents will advise members who include the Fair in their itineraries concerning the most advantageous arrangements.

A communication to the entire membership will be mailed shortly by the New York Central Railroad giving additional information concerning travel to Indianapolis direct and via Chicago from all parts of the United States. Names of representatives in different sections will be given so that exact local details may be easily obtained.

INDIANAPOLIS IS CENTRALLY LOCATED

INDIANA AND SURROUNDING STATES

THE above map indicates the location of Indianapolis with reference to the center of population of the United States, which, according to the 1930 census, is approximately sixty miles southwest of this city.

For those attending the Annual Meeting of the American Public Health Association who are interested in seeing the

World's Fair at Chicago, it is interesting to note that there are three main paved highways from Indianapolis to Chicago, driving distance less than 200 miles. Railroad connections between Indianapolis and Chicago over the Big Four-New York Central, Pennsylvania and Monon include 17 trains daily, average running time four hours.

The Preliminary Program of the Scientific Sessions of the Annual Meeting, and other important information, will be published in the September issue.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- Robert M. Dodsworth, City Hall, Venice, Calif., Assistant Health Officer
 E. A. Garrett, M.D., 804 Peoria Life Bldg., Peoria, Ill., Commissioner of Health
 Earl E. Hansen, 369 Chorro St., San Luis Obispo, Calif., Sanitary Inspector, County Health Department
 Oscar D. Ludwig, M.D., 5433 Madison Ave., Indianapolis, Ind., Health Commissioner, Marion County
 Elmer T. McGaugh, M.D., Capitol Bldg., Jefferson City, Mo., Health Commissioner
 J. Cyrille Pomerleau, M.D., Beauceville East, Beauceville County, P. Que., Canada, County Health Commissioner
 Leslie A. White, M.D., Metlakatla, Alaska, Physician, Indian Field Service, U. S. Dept. of the Interior

Laboratory Section

- K. George Falk, Ph.D., 151 Central Park West, New York, N. Y., Biological Chemist, Bureau of Laboratories, Department of Health
 Francis A. Halliday, A.B., 3505 N. Calvert St., Baltimore, Md., Student (Assoc.)
 G. M. Pulkrabek, B.S., 608 S. Dearborn St., Chicago, Ill., Milk Sanitation and Control

Public Health Engineering Section

- Edmond Mallet, 2236 Cathedral Ave., N.W., Washington, D. C., Assistant Inspector of Plumbing, District of Columbia

Child Hygiene Section

- Bernice Wright, Box 320, Monroe, La., Executive Secretary, Ouachita Tuberculosis and Public Health Ass'n

Public Health Education Section

- Ina J. N. Durfee, Wolfeboro Camp, Wolfeboro, N. H. (Assoc.)

Food and Nutrition Section

- S. H. Crounse, 10 Vista Road, Madison, Wisc. (Assoc.)
 Raymond Hertwig, B.S., A.M.A., 535 N. Dearborn St., Chicago, Ill., Secretary, Committee on Foods
 Horace I. Lepman, 228 S. Wabash Ave., Chicago, Ill., Acting Superintendent, Division of Foods and Dairies, State Dept. of Agriculture

- Katherine Lloyd, B.S., Armour & Co., Union Stock Yards, Chicago, Ill., Nutritionist
 K. M. Royer, B.S., 608 S. Dearborn St., Chicago, Ill., Milk Sanitation
 Mervyn B. Starnes, D.V.M., Department of Public Health, Dallas, Tex., City Veterinarian

Public Health Nursing Section

- Alice L. Haviland, R.N., 2573 E. 55 St., Cleveland, O., Assistant Director, University Nursing District
 Edwina Mattingly, R.N., Shepherdsville, Ky., Bullitt County Public Health Nurse
 Virginia E. Moore, Pi Beta Phi Settlement School, Gatlingburg, Tenn., School and Public Health Nurse

Unaffiliated

- Joseph M. Dailey, D.M.D., 1478 Dorchester Ave., Dorchester, Mass. (Assoc.)
 Nelson W. Strohm, M.D., 87 W. Tupper St., Buffalo, N. Y., Diagnostician, City Health Dept.
 Burchard A. Winne, M.D., 28 N. Market St., Johnstown, N. Y. (Assoc.)

Sustaining Member

- The Travelers Insurance Company, Hartford, Conn.

ADDITIONAL APPLICANTS FOR FELLOWSHIP

Health Officers Section

- Russell E. Hobbs, M.D., Wichita, Kans.

Laboratory Section

- James A. Kennedy, Ph.D., Augusta, Ga.
 Merl P. Moon, Ph.D., Columbia, Mo.

Public Health Engineering Section

- Harold E. Babbitt, M.D., Urbana, Ill.

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, pro-

viding such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Indianapolis will be elected for the three-year term, 1933-1936.

Dr. Carl Alsberg,
Food Research Institute,
Stanford University, California.

James N. Baker, M.D.,
State Health Officer,
Montgomery, Alabama.

J. Bronfenbrenner, Ph.D.,
Department of Bacteriology,
Washington University,
St. Louis, Missouri.

Walter H. Brown, M.D.,
Stanford University,
Palo Alto, California.

John Collinson, M.D.,
State Department of Health,
Baltimore, Maryland.

Platt W. Covington, M.D.,
1119 Alpine Avenue,
Salt Lake City, Utah.

S. J. Crumbine, M.D.,
American Child Health Association,
450-7th Ave., New York, New York.

A. J. Douglas, M.D.,
City Health Department,
Winnipeg, Manitoba.

Mary J. Dunn,
Vanderbilt University,
School of Nursing,
Nashville, Tennessee.

W. Thurber Fales, Sc.D.,
Director, Bureau of Vital Statistics,
State Board of Health,
Montgomery, Alabama.

W. H. Frost, M.D.,
Johns Hopkins University,
615 N. Wolfe St.,
Baltimore, Maryland.

Paul Hansen,
6 N. Michigan Avenue,
Chicago, Illinois.

I. Malinde Havey,
National Director,
Public Health Nursing Service,
American Red Cross,
Washington, D. C.

Emery R. Hayhurst, M.D.,
1925 Concord Road,
Columbus, Ohio.

Albert H. Jewell,
1020 McGee Street, Room 400,
Kansas City, Missouri.

H. E. Kleinschmidt, M.D.,
National Tuberculosis Association,
450-7th Ave., New York, New York.

John P. Koehler, M.D.,
City Hall,
Milwaukee, Wisconsin.

Sophie C. Nelson, R.N.,
Director, Nursing Service,
John Hancock Mutual Life Ins. Co.,
Boston, Massachusetts.

George T. Palmer, Dr.P.H.,
American Child Health Association,
450-7th Ave., New York, New York.

Thomas Parran, Jr., M.D.,
State Department of Health,
Albany, New York.

Lowell J. Reed, Ph.D.,
Johns Hopkins University,
School of Hygiene and Public Health,
Baltimore, Maryland.

Milton J. Rosenau, M.D.,
20 Chapel Street,
Brookline, Massachusetts.

R. R. Sayers, M.D.,
U. S. Bureau of Mines,
Washington, D. C.

Prof. Henry C. Sherman,
Dept. of Chemistry,
Columbia University,
New York, New York.

James A. Tobey, Dr.P.H.,
Borden Sales Company,
350 Madison Avenue,
New York, New York.

H. A. Whittaker,
Division of Sanitation,
State Board of Health,
Minneapolis, Minnesota.

Fred O. Tonney, M.D.,
City Hall, Room 712,
Chicago, Illinois.

C.-E. A. Winslow, Dr.P.H.,
Yale University,
New Haven, Connecticut.

Radio Broadcast

A new series of weekly health broadcasts, under the auspices of the American Public Health Association, began on Wednesday, June 28th, over the National Farm and Home network. The opening talk on the "Health Budget" was given by Dr. Fred O. Tonney, Head of the Research Staff of the Chicago Board of Health.

The series which is titled "A Nation's Investment in Health," will continue on Wednesdays, at about 12:35 central daylight time, during the summer, and will feature authoritative speakers from the membership of the Association on a variety of subjects.

The National Broadcasting Company and particularly its Agricultural Director, Mr. Frank E. Mullen, are to be commended for the unusual vision and public spirit manifested by them in arranging these broadcasts for the American Public Health Association.

The series is under the direction of the "President's Committee," appointed by the Executive Board for the express purpose, at the last annual

convention in Washington, D. C. The committee has "power to act in negotiating and making arrangements to broadcast programs in the name of the American Public Health Association."

The committee consists of Dr. Louis I. Dublin, New York, Chairman, past president of the Association and Vice-President of the Metropolitan Life Insurance Company, Dr. John A. Ferrell, New York, president, Dr. Haven Emerson, New York, president-elect, Dr. Kendall Emerson, New York, Acting Executive Secretary, and Dr. Fred O. Tonney, Chicago, Radio Advisor.

All statements broadcast in the name of the Association will be carefully censored by the committee and hence may be accepted as accurate and reliable within the present state of scientific knowledge. Suggestions for subjects of further broadcasts are solicited and should be addressed to the American Public Health Association, 450 Seventh Ave., New York, N. Y.

The list of speakers and topics were published in the July issue.

PUBLIC HEALTH ADMINISTRATION

Hartford, Conn.—For economy reasons, the 1931 and 1932 records of this city of 170,120 population in 1932 are printed in one report. Ordinance requirements specify a report to the Court of Common Council in March, and such a report was made each year in manuscript form. Among the readjustments since the previous report are noted the transfer of the isolation hospital to the Board of Public Welfare where it is operated as a unit of the municipal hospital. The Board of Health laboratory is housed in this hospital, beside the hospital laboratory, and does the bacteriology and serology work for the institution. Hartford received honorable mention in the U. S. Chamber of Commerce Health Conservation Contest.

The first death from diphtheria in three years occurred in 1932. This was an adult, and the possibility of diphtheria seems to have been overlooked by the attending physician. The death rate from tuberculosis was 50.05 in 1932 as compared with 65.6 the previous year.

Edmonton, Alberta—In 1932, this city of 78,387 recorded a death rate of 7.9 as compared with 6.4 the previous year. The area of the city is 26,520 acres, including 1,000 acres of water. Hence there are some three persons per acre. The school enrollment numbered 18,353, while 2,340 births gave a rate of 19.5. An infant mortality rate of 44.2 is creditable. There were only 3 cases of diphtheria with no deaths. Diphtheria immunizations by official organizations numbered 1,514. Two well baby clinics are held each week in the city.

New Britain—The 1932 health department report indicates that in no previous year has the health record of this industrial city equalled that of the year reported. A general death rate of 7.5, an infant mortality rate of 54.3, and a tuberculosis rate of 60 are noteworthy. Whooping cough cases numbered 530 with 3 deaths, however, in contrast with 119 cases and 1 death the previous year.

Due to economic conditions, the scope of the dental clinic, originally for school children, increased to serve adults referred by the Mutual Aid Association and the Welfare Department. This clinic is located in the City Hall. The report concludes with recommendations for an isolation hospital, for municipal collection of refuse, and for the transfer of collection of garbage expenditures from the health department.

Brookline, Mass.—In 1932, Brookline, with an estimated population of 49,560, reported a birth rate of 9.04, a death rate of 11.18, and an infant mortality rate of 46.9 per 1,000 births. Diseases of the heart (146) and cancer (82) lead the list of causes of death. Seven cases of diphtheria with one death occurred during the year. Since 1922, 8,974 children have been immunized against diphtheria—672 having been protected last year.

A table showing improvement in the milk supply since 1925 is of interest. The average bacteria count per c.c. has dropped from 118,495 in 1925 to 8,944 for market milk; from 39,022 to 5,501 for Grade A; from 52,975 to 2,049 for Special milk, and from 6,860 to 1,392 for Certified milk. The per capita milk consumption is .98 pint, a figure

somewhat lower than for previous years.

A city-wide attempt was made to eradicate ragweed, the pollen of which causes "hay fever" during early fall months. Inspectors, while making a house to house search for fly and mosquito breeding places, made note of places where ragweed was found growing. Property owners were notified and coöperated in destroying the weed. A detail of welfare labor and a truck under a health department inspector was assigned to the task of aiding in the prompt destruction and removal of the weed. This work will be continued as a part of the 1933 program.

Brookline was awarded first place in the U. S. Chamber of Commerce Health Conservation Contest for cities within the 20,000 to 50,000 population group. The city health bulletin, published quarterly, is distributed by the Police Department to every house in town.

Attleboro, Mass.—Attleboro, with an estimated population of 22,187, reports a death rate of 12.8 per 1,000, with heart disease (49), and cancer (33) leading the list of causes of death for 1932. In 1931, a local survey showed 66.6 per cent of the school population and 60.8 per cent of the preschool group immune to diphtheria. In 1932, 515 children were immunized, and of these 333 were of preschool age.

The Chamber of Commerce, through its Health Committee, sponsored a campaign urging the use of more pasteurized milk. A regulation requiring pasteurization or certification of all milk sold in the city was adopted during the year, but will not be immediately enforced because of financial difficulties. All tuberculous cows are being removed from herds supplying the city with milk.

The year 1932 marks the tenth year of the Health Camp for undernourished boys, funds for the camp being furnished through the Community Chest.

As a result of the examination of a large group of undernourished children by the health department, 40 boys were enrolled in this six-week camp. The maximum gain in weight was $23\frac{3}{4}$ lb.; the minimum $4\frac{3}{4}$ lb. Statistical tables and reports of the various bureaus conclude this 24-page report.

Warwick, R. I.—The second annual report of Warwick, for the year 1932–1933, is well printed, but on glossy paper, with appropriate headings and sub-headings in dark print to facilitate reading. Charts, graphs and pictures aid in making this a well balanced report.

Opening with a historical sketch of the town, which was settled in 1642, the report follows the general outline of the appraisal form for rural health work of the American Public Health Association. The city scored 765 out of 1,000 possible points, as compared with 711 for the previous year. An organization chart and a detailed list of the duties of various members of the health department are of interest.

Based on an estimated population of 25,329 for 1932, the city reports a birth rate of 15.6, a death rate of 11.4 and an infant mortality rate of 73.2. With the exception of scarlet fever, pneumonia and septic sore throat, all communicable diseases in the city showed a decrease in number of cases during the year. The tuberculosis rate dropped 14 points—from 57.4 in 1931 to 43.4 in 1932.

Of the 396 births, 55 per cent occurred in homes attended by physicians; 41 per cent in hospitals, and only 4 per cent were attended by midwives. This is a well written, compact report of 33 pages.

Lorain County General Health District—According to the 1932 annual report of the Lorain County (Ohio) General Health District, the population

of the area served is 40,305. The death rate was 11.4, an increase of 1.8 over the previous year. A total of 2,131 cases of communicable diseases was reported to the health department, the largest number in the history of the department. There were 5 cases of tularemia reported as associated with unprotected handling of wild rabbits. A total of 2,032 visits was made by staff members to the cases of communicable disease, and 341 visits to suspects. During the year 1,040 vaccinations or revaccinations were given.

The Blue Ribbon Program is used in schools. There were 6,154 children enrolled in the schools in 1932. A total of 5,838 defects was found; 2,329 defects were corrected, and 1,796 children received the award of Blue Ribbons.

In 1931, the daily consumption of

milk was 1,400 gallons, with 75 per cent pasteurized. During 1932, only 1,300 gallons of milk per day were consumed and the proportion pasteurized was 71 per cent.

The laboratory made a total of 4,086 examinations, an increase being noted as largely due to communicable disease work, and the increased use of facilities by physicians of the county.

An active program in health education was carried on during the year; formal talks were given to Parent-Teacher Associations; 500 copies of the 1931 annual report were printed and distributed. More than 26,000 pieces of mimeographed material were printed and distributed. Booths were set up at both the Wellington and Elyria fairs.

The per capita cost of the health department from county and state funds was 54 cents.

LABORATORY

VALUE OF CULTURE TESTS IN THE DIAGNOSIS OF DIPHTHERIA*

HAZEL M. HATFIELD, M.D., AND ALICE G. MANN

Bureau of Laboratories, New York City Health Department

THE question has arisen as to the advisability of continuing to use routine cultures as an aid in the diagnosis of suspected diphtheria. The fundamental diphtheria culture work of Dr. William H. Park in the early years of the problem led to the estab-

immunization on a large scale, however, the problem of diphtheria control work undoubtedly enters a new phase and the value of the routine culture examination should be re-appraised.

The very excellent studies made by Godfrey of the influence of diphtheria

TABLE I

| <i>Diphtheria Morbidity</i> | | <i>Diphtheria Mortality per 100,000 of Population</i> | | | |
|-----------------------------|--------|---|-----|-----------|-------|
| 1925..... | 9,051 | 1925..... | 663 | rate..... | 10.49 |
| 1926..... | 7,531 | 1926..... | 477 | rate..... | 7.39 |
| 1927..... | 13,507 | 1927..... | 717 | rate..... | 10.90 |
| 1928..... | 10,776 | 1928..... | 642 | rate..... | 9.57 |
| 1929..... | 8,548 | 1929..... | 463 | rate..... | 6.77 |
| 1930..... | 3,794 | 1930..... | 198 | rate..... | 2.84 |
| 1931..... | 3,999 | 1931..... | 186 | rate..... | 2.62 |

lishment of this test as the accepted means of diagnosis and of guidance to necessary public health control measures. It is now in world-wide use and has increased in volume from year to year to an enormous extent.

The virulence test—a necessary concomitant of the microscopic test—is complicated and requires a number of days; the microscopic examination is relatively simple and quick. Except in the unusual case, therefore, the latter test stands alone as a guide to the public health authorities and to the physician.

With the introduction of diphtheria

immunizations on diphtheria mortality indicate that at least 30 per cent of young children must be immunized before a significant reduction in the diphtheria death rate is effected. Immunization work on a big scale has been carried forward in New York City since 1929 and it is estimated that 36 per cent of New York children under six years of age have now been immunized against diphtheria.

With this large and increasing immune child population one would logically expect a decrease, not only in the diphtheria morbidity and mortality, but in the amount of culture work sent into the laboratory for examination.

As a matter of fact, we find that, since the middle of 1929, the number

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

of cases reported has always been well below the expected number. The mortality figures also show a marked drop. These facts are shown more fully in Table I.

The culture work sent in for diphtheria diagnosis has shown no corresponding decrease in volume. A study of Table II shows that there was a decided drop in 1930 but the figures for 1931 and 1932 again show an up-

the days before immunization work was begun and should the physician still consider it the best practice to send in a culture from every case that even remotely might be diphtheria? May it not be true that more immune individuals harbor the diphtheria bacillus and, if so, will the organism more likely be non-virulent? If this presumption should prove to be true, a positive diphtheria report may readily

TABLE II
DIPHTHERIA CULTURE EXAMINATIONS

| | Primary | | Unsatisfactory | Total | Total | School | Laters | Total |
|-----------|----------|----------|----------------|--------|--------|--------|---------|---------|
| | Positive | Negative | | | | | | |
| 1925..... | 5,338 | 40,066 | 789 | 46,193 | 10,290 | 1,302 | 63,426 | 121,211 |

| 1927..... | 7,898 | 55,087 | 834 | 63,819 | 5,643 | 2,552 | 117,868 | 189,982 |
| 1928..... | 6,198 | 49,164 | 4,560 | 59,922 | 4,763 | 1,428 | 131,786 | 197,899 |
| 1929..... | 5,064 | 44,185 | 2,821 | 52,070 | 2,757 | 1,324 | 105,528 | 161,679 |
| 1930..... | 2,093 | 33,096 | 1,212 | 36,401 | 428 | 261 | 73,943 | 111,033 |
| 1931..... | 2,947 | 30,116 | 2,085 | 35,148 | 1,169 | 313 | 100,722 | 137,352 |
| 1932..... | 3,272 | 31,273 | 1,936 | 36,481 | 714 | 1,380 | 129,829 | 168,404 |

ward trend. The primary cultures for 1927, 1928 and 1929 are much higher in number than those for 1930, 1931 and 1932, but the totals of all the diphtheria culture examinations for 1930, 1931 and 1932 are again approaching the totals for the peak years of 1927, 1928 and 1929. For the same years (1927 to 1931) the census shows a moderate but more or less steady decrease in the total child population under 5 years of age. (The figures for the 6-year group are not obtainable.)

In Table II it becomes apparent that the increased totals for 1931 and 1932 are due very largely to the increased numbers of later cultures. And this brings us to the question of carriers and then to a consideration of the effect of a large immune population upon the presence of virulent versus non-virulent diphtheria organisms in the throats of these carriers. Has the carrier the same significance and importance now as in

confuse the diagnosis and thus deprive the patient of proper medication—substituting for it a dose of antitoxin which the patient may not need and, if the patient survives, putting on record another carrier whose particular strain of diphtheria organism eventually proves to be non-virulent.

Having in mind the above considerations, an attempt has been made to determine the type of case giving a positive primary culture compared with the type of case giving a negative primary culture. Data have also been obtained regarding previous immunization of the positive cases. Lastly, a study has been made of the virulence of the diphtheria strains so isolated.

Positive primary cultures were selected at random, the physician contacted in each case for pertinent data and the culture subjected to virulence test. These findings have been summarized in Table III.

TABLE III
POSITIVE DIPHTHERIA CULTURES IN RELATION TO TYPE
OF CASE AND VIRULENCE DETERMINATION

| Type of case | No. of cases | Under 6 yrs. | 6-16 yrs. | Adult | Exposure | | Immunization | | | | Virulence | |
|--|--------------|--------------|-----------|-------|----------|----|--------------|---------|----|---|-----------|------|
| | | | | | Yes | ? | Yes | Partial | No | ? | Pos. | Neg. |
| Clinically diphtheria | 18* | 7 | 8 | 3 | 4 | 14 | 4 | 0 | 13 | 1 | 6 | 12 |
| Clinically not diphtheria | 12 | 8 | 2 | 2 | 0 | 12 | 2 | 3 | †6 | 1 | 4 | 8 |
| Routine (camp, institution, hospitals) | 9 | 5 | 4 | 0 | 0 | 9 | ‡5 | 1 | 3 | 0 | 0 | 9 |
| Trials (contacts) | 4 | 3 | 1 | 0 | 4 | 0 | 0 | 0 | 3 | 1 | 1 | 3 |

* One case (of membranous croup) died. All the other cases recovered.

† One of these cases had received a first dose of T.A.T. six days before illness began.

‡ Of these five children, one had had diphtheria and four had had T.A.T. One had given a negative Schick.

In comparison with the positive cases tabulated above, the clinical diagnosis in 19 cases having a negative culture are stated as follows:

- 1 diphtheria
- 6 tonsillitis
- 2 spasmodic croup
- 1 croup
- 1 Vincent's infection of the mouth
- 1 acute pharyngitis
- 1 septic sore throat
- 4 rhinitis (one purulent)
- 1 acute laryngitis with stridor
- 1 post-tonsillectomy condition

The positive cultures classified as virulent or non-virulent in Table III have been further correlated with the history of immunization in each case with the results shown in Table IV.

In conjunction with the virulence table, a number of cases are cited because of their unusual features:

1. A child of 21 months was admitted to the hospital on the third day of illness with a diagnosis of membranous croup. There was a so-called typical laryngeal membrane. Fifteen thousand units of antitoxin was given

intramuscularly and 10,000 units intravenously on admission. Four cultures taken on admission—2 from the throat, 1 from the nose and 1 from the pharynx—all showed a morphologically

TABLE IV
VIRULENCE FINDINGS IN RELATION
TO IMMUNIZATION

| Type of Case | Virulent | | Immunization | | | |
|-----------------------------------|----------|----|--------------|---------|----|---|
| | Yes | No | Yes | Partial | No | ? |
| Clinically diphtheria | 6 | — | 1 | 0 | 4 | 1 |
| | — | 12 | 2 | 0 | 10 | 0 |
| Clinically not diphtheria | 4 | — | 1 slight | 1 | 2 | 0 |
| | — | 8 | 1 | 2 | 4 | 1 |
| Routine camp institution hospital | 0 | — | 0 | 0 | 0 | 0 |
| | — | 9 | 5 | 1 | 3 | 0 |
| Trials (contacts) | 1 | — | 0 | 0 | 1 | 0 |
| | — | 3 | 0 | 0 | 2 | 1 |

typical diphtheria bacillus. The child died 2 days later. On virulence test, however, all 4 cultures proved to be non-virulent in guinea-pigs of proved susceptibility.

2. In a boarding-home for poor children, a 2-year old child became ill with very moderate symptoms, fever and a suggestion of a membrane, slightly indicative of diphtheria. The child had never been immunized and was ill only a day and a half. A throat culture was positive and the culture was virulent. *But*, of the 5 other children in the home and in contact with the patient, none of whom had been immunized, one other child was ill with a typical follicular tonsillitis and had a negative throat culture, and two had positive throat cultures which were non-virulent. The child with tonsillitis gave a very strong Schick reaction. Incidentally, the two positive contacts continued to be positive and were released from quarantine as carriers only after their inclusion in this special study had proved them to be non-virulent.

3. A culture from a child with a temperature of 104 and large, congested tonsils was found morphologically posi-

tive for diphtheria. The patient was recovered in 24 hours. This child had a history of repeated sore throats and plans were under way to have a tonsillectomy performed. There was no membrane. Six days prior to onset of illness the child had received his first dose of T.A.T. at the Health Department. The physician felt very sure that this was not a diphtheritic infection and was extremely annoyed at the routine quarantine restrictions. This culture proved to be non-virulent.

4. A patient with a typical case of diphtheria, a positive throat culture and with a residual paralysis of the soft palate and nasal voice was found to be the carrier of a non-virulent strain.

5. A child of 4 years, after a month of hospitalization for treatment for hematuria, developed a running nose and "cold." A routine culture was morphologically positive for diphtheria but was non-virulent on further test.

A summary of the virulence work performed in the Health Department Laboratory, exclusive of those tested in the Willard Parker Hospital, shows the following:

TABLE V
SUMMARY OF ROUTINE VIRULENCE FINDINGS

| Year | Virulent | Non-virulent | Total | Child Population Under 5 Years |
|---------------------|----------|--------------|-------|--------------------------------|
| 1927 | 48 | 44 | 92 | 553,000 |
| 1928 | 31 | 50 | 81 | 551,000 |
| 1929 | 11 | 86 | 97 | 548,000 |
| 1930 | 8 | 63 | 71 | 536,000 |
| 1931 | 7 | 129 | 136 | 531,000 |
| 1932 (9 months).... | 8 | 147 | 155 | Figures not obtainable |

The facts here adduced tend to show that there has been a shift in the diphtheria situation. This is borne out by the laboratory data. There has not been a reduction in the laboratory tests sent in at all commensurate with the immunity work accomplished. The question arises as to how far the phy-

sicians are justified in sending cultures for diphtheria examination and at what point the natural barriers of more or less universal immunizations will obviate the demand for laboratory tests on this big scale. At what point will the great expense of this work no longer be justified? And, much more

important, will it be true that, if the number of carriers of non-virulent diphtheria bacilli increases markedly as the immunity work progresses—a situation at least suggested by the above facts—will it not be true that a positive laboratory report will confuse the diagnosis and cause to be treated as diphtheria many cases of streptococcal, influenzal and other type infections? Under these new conditions a positive

culture would become merely a presumptive indication that the case was one of diphtheria and should not of itself cause quarantine unless the case clinically would justify such a diagnosis.

When will the carrier cease to be more than a remotely potential menace and when may the laboratory expect to rid itself of an amount of microscopic examinations which gives no indication of dropping away spontaneously?

A CONVENIENT FECES SPECIMEN CONTAINER

M. FROBISHER, JR.

*The Eastern Health District Laboratory, The Johns Hopkins University,
School of Hygiene and Public Health, Baltimore, Md.*

IN obtaining specimens of feces for bacteriological examination it is often the practice to leave with the patient a small bottle or other container with the request that the specimen be put therein. The patient is many times left to devise a means of actually transferring a suitable portion of the fecal deposit into the container and the results are frequently unsatisfactory. Either the patient is not sufficiently ingenious to meet the situation and solves the problem by presenting a tomato can with an entire stool or else loses interest and fails to save a specimen. The use of a teaspoon or kitchen knife is inadvisable on sanitary grounds, for esthetic reasons and because of the possibility of introducing pathogens into the specimen from an outside source—possibly from some other carrier in the family.

A sterile wooden spatula is sometimes sent with the specimen container. This is frequently mislaid, suitable dis-

posal may be difficult and contamination or infection from the spatula during handling may occur.

An outfit was devised to avoid these disadvantages and is now in use in this laboratory. It consists simply of a 2 ounce, wide-mouth glass bottle with a cork stopper. A wooden tongue blade is cut into halves and one end of each piece is whittled to a sharp, flat point which is thrust firmly into a cut in the narrow end of the cork, the cut in the cork having previously been made with a paring knife. The cork is then fitted into the bottle and the whole sterilized in the hot air oven at 170 C. for 2 hours.

A good grade of cork or a rubber stopper must be used in order to avoid leakage if pressure develops. If a preserving solution is used, sterilization may be accomplished in steam.

A slightly more expensive modification of this outfit may be made from

sheet metal. The wooden paddle is replaced by a piece of metal, and this may be fastened with a few drops of solder (necessitating steam sterilization) to the inside of a metal clamp—or screw-cover, very much in the same manner as small brushes are supplied in cans of certain brands of automobile "touch-up" paint. The possibility of bactericidal or bacteriostatic effects due to the metal must be taken into consideration before adopting such a device. Much will depend on the distance, time and temperatures involved in transporting the material to the laboratory. Both types of paddle can be used more than once. Metal paddles can be made spoon-shaped to facilitate the collection of liquid material.

In collecting the feces specimen the spatula always remains with the bottle, it is not touched by anyone and no disposal or esthetic problem arises.

VITAL STATISTICS

Diphtheria Mortality in Large Cities of the United States in 1932—Reports from 93 cities in the United States, showing the number of diphtheria deaths recorded in 1932, presents a pretty good index of the diphtheria situation during the last year.

Among the ten cities with the lowest diphtheria death rates were five (Albany, Grand Rapids, South Bend, Utica, and Yonkers) which escaped recording a single death rate from diphtheria in 1932. The five cities with the next lowest rates were St. Paul (0.3), Seattle (0.3), Newark (0.4), Syracuse (0.5), and New Haven (0.6).

The ten cities with the highest diphtheria mortality were Dallas (16.3), Knoxville (15.2), Peoria (12.6), Fort Worth (11.7), Lowell (11.0), Wichita (9.2); Camden (8.4), Des Moines (8.2), Oklahoma City (8.2), and Memphis (7.6).

Geographical arrangement of the cities finds those in the Middle Atlantic states with an aggregate diphtheria mortality of 2.5 per 100,000 in 1932, thereby improving their excellent record of 2.8 in 1931 and easily maintaining their ranking as the group having the lowest diphtheria mortality. Three of the five American cities that did not register a single death from diphtheria in 1932 are in this geographic division. It is suggestive of the fact that several cities in this group were among the first in the country to put into practical application modern methods of diphtheria control. New York, for the third consecutive year, reported a very low rate—one of 2.9, this being slightly higher than the 1931 figure of 2.6 but identical with the 1930 rate of 2.9. Special attention may be directed to the low rate for

1932 in Philadelphia (0.8), the best record yet achieved by any American city with a population of more than a million. The City of Camden, for the second year in succession, registered the highest diphtheria mortality rate of the cities in this group with a figure of 8.4 per 100,000.

The New England group again made a new low record (3.65). The Connecticut municipalities, led by New Haven, have had a notably smaller diphtheria mortality than the Massachusetts cities in recent years. Bridgeport, after several years of an intensive control campaign, made a particularly fine showing in 1932, the single diphtheria death reported being that of a nonresident. The diphtheria mortality rate of 4.2 in Boston was lower than for the year before (4.7) although not quite equalling its banner year 1930 when a rate of 2.9 was recorded. Lowell, however, experienced a considerable increase in diphtheria in 1932, showing a death rate of 11.0 in contrast to the figure of 5.0 in 1931. Worcester, after experiencing diphtheria mortality of 1.5 per 100,000 population in 1930 and 4.0 in 1931, recorded a rate of 6.0 in 1932.

Several of the cities in the South Atlantic states showed notable improvement over preceding years. Among these were Richmond, which recorded the low diphtheria death rate of 1.1 in 1932 in contrast to 5.4 in the preceding year; Baltimore with rates of 1.8 and 2.8 in 1932 and 1931 respectively; and Wilmington with 1.9 and 6.6 for the same two years. The three Florida cities, Tampa (4.6), Jacksonville (7.1), and Miami (7.3) on the other hand, reported rates that indicate an excessive prevalence of diphtheria. It might also be noted that

Miami in 1932 recorded more than double the diphtheria rate in New York.

The East North Central group of cities which in 1925-1929 had the highest average diphtheria mortality of any section of the country, has made the greatest relative improvement and now with a combined death rate of 2.7, its diphtheria record ranks second only to the Middle Atlantic Cities, which had a rate of 2.5 in 1932. A notable decrease in diphtheria fatalities was shown by Cleveland which had a diphtheria death rate of 1.4 in 1932, 1.2 in 1931, and 4.1 in 1930, after having experienced a rate of 15.3 for the five-year period 1925-1929. Detroit and Chicago also have recorded spectacular reductions in diphtheria mortality in recent years; Chicago, especially, has made remarkable strides in bettering its record, dropping to a diphtheria death rate of 1.9 in 1932 as compared with 6.2 in 1931 and 12.2 in 1930. Dayton and Fort Wayne with diphtheria death rates of 7.7 and 5.8, respectively, seem to have had an unusual prevalence of the disease; Peoria, with a death rate of 12.6, apparently had a real epidemic.

The East South Central cities, as a whole, did not show much change from the high rates of the preceding year. The cities, as a group, had a diphtheria mortality of 6.1 in 1932 as compared with 6.9 in 1931 and 5.0 in 1930.

Six of the eight West South Central cities showed an increase in 1932 over 1931, and the group as a whole had an average rate of 8.2 in 1932, as against 5.9 in 1931. Fort Worth and Dallas, with diphtheria death rates of 11.7 and 16.3, respectively, seem to have been the chief sufferers from this disease. It is curious that diphtheria should now be so relatively prevalent in this region, since from 1900 to 1920 the cities of the Southwest had considerably less diphtheria mortality than the rest of the country.

The group of cities in the Mountain and Pacific States showed an increase in the diphtheria rate from 2.7 for 1931 to 3.4 for 1932; Tacoma, the only city in this group to record a reduction, registered rates of 0.9 in 1932 and 8.3 in 1931. Seattle, with a rate of 0.3, and Salt Lake City with a rate of 0.7, had the best records of this group in 1932.—*J.A.M.A.* 100:1595-1597 (May 20), 1933.

Provisional Figures for Live Births, Infant Mortality, and Stillbirths in the Birth Registration Area (Exclusive of Massachusetts and Utah) in Continental United States, 1932—The Bureau of the Census announced that in the birth registration area of continental United States (exclusive of Massachusetts and Utah) during the calendar year 1932 there were 1,961,618 births, 113,661 deaths of infants under one year of age, and 75,175 stillbirths. These figures are equivalent to a birth rate of 17.3 per 1,000 population, an infant mortality rate of 57.9 per 1,000 live births, and a stillbirth rate of 3.8 per 100 live births. The corresponding final rates for 1931 for the same area were 18.0, 61.9, and 3.8, respectively.

The birth rate of 17.3 for the 44 states and the District of Columbia covered by this press release is the lowest since the establishment of the Federal birth registration area in 1915. The infant mortality rate (57.9) is also lower than for any previous year. The stillbirth rate (3.8) is the same as for 1931 and has varied but very little since 1922, in which year the annual collection of stillbirth records was begun.

The urban part of the birth registration area of 1932, except Massachusetts and Utah, includes 864 cities, towns, and townships, with an estimated total population of 54,979,000 on July 1, 1932. In this urban area there were 896,334 births, 51,136 deaths of

infants under one year of age, and 35,317 stillbirths. The rural part had an estimated population of 58,367,000, among which there were 1,065,284 births, 62,525 infant deaths, and 39,858 stillbirths. In the urban portion of the area the birth rate was 16.3 per 1,000 population, the infant mortality rate 57.1 per 1,000 live births, and the stillbirth rate 3.9 per 100 live births. The corresponding rates for the rural portion of the area were 18.3, 58.7 and 3.7 respectively.

Naturally, the greatest number of births occurred in the most populous states—New York, having 198,353, Pennsylvania, 168,533, Illinois, 111,512, and Ohio, 101,043. The highest birth rates, however, were for New Mexico, 28.0, North and South Carolina, each 23.7, and Alabama, 23.5. Nevada,

Wyoming, and Delaware had the smallest number of births, 1,244, 4,231, and 4,264, respectively, but the states having the lowest birth rates were California and Oregon, each with 13.1, Nevada and Washington, each with 13.4, and Illinois, with a rate of 14.4.

The greatest number of deaths of infants under one year of age occurred in New York (10,446), Pennsylvania (10,107), and Ohio (5,961). The highest infant mortality rate was for New Mexico (113.6), which was the only state with a rate higher than 100.0 per 1,000 live births. Other states with high infant mortality rates were Arizona (94.5), Colorado (73.2), District of Columbia (72.9), South Carolina (76.6), and West Virginia (75.3). —U. S. Department of Commerce, Bureau of the Census. *Press Release.*

PUBLIC HEALTH ENGINEERING

A DEEP WATER SAMPLING ROD

LOUVA G. LENERT

*Chief Engineer, Bureau of Engineering, Florida State Board of Health,
Jacksonville, Fla.*

THE first requisite of shellfish sanitation is that the growing areas from which they are taken must be approved by the state agency having jurisdiction over same. To determine the fitness of these areas for shellfish production requires extensive physical surveys of the shore line and contributing drainage area. When this survey indicates considerable pollution of the water a bacteriological survey of the waters over the producing areas becomes necessary. Samples of water are taken under different wind and tidal variations to determine their effect upon the distribution of pollution. Surface samples in some cases may give a fair index of actual conditions, but bottom samples are more indicative of the condition of the growing area itself.

The deep water sampling rod illustrated was first developed by C. D. Hopkins, M.D., for taking samples of water from Hillsborough Bay below the City of Tampa, Fla., at depths varying from two to twelve feet. Very rapid progress can be made with this device which is operated as follows:

All sampling is done over the side of

a boat. Upon nearing the point where a sample is desired the sterile cover is removed from the top of the water sample bottle, which is then inserted in the cup at the bottom of the rod, being held firmly in place by the neck-clip. The top holder is expanded and allowed to slip into the groove of the ground glass stopper as is shown in the large scale illustration. The lugs and spring which serve to keep the top holder closed also prevent the stopper from slipping out. The stopper is then given a half turn to be certain it is not stuck tight, being careful not to permit the fingers to touch the top of the bottle.

As the boat arrives at the appointed spot, the operator plunges the rod forward in the direction of travel and down to the depth desired. When the rod reaches the vertical position the cord attached to the eye of the top holding bar is pulled momentarily to permit filling of the bottle and is then released. The rod is then brought into the boat and the bottle is removed to the carrying case and a new bottle is inserted for the next sample.

CHILD HYGIENE

REPORT OF THE PRESCHOOL CENTER PROGRAM OF THE CLEVELAND CHILD HEALTH ASSOCIATION

E. V. THIEHOFF, M.A., M.D.

Acting Director, Cleveland Child Health Association, Cleveland, Ohio

REALIZING that the health and welfare of the infants in Cleveland are well provided for in the infant welfare stations of the Cleveland Division of Health and that the school children are given health supervision in the public and parochial schools, but that little attention is being given to the preschool child, the Cleveland Child Health Association decided to set up a program of preschool centers as a step toward meeting the existing needs for this age group. In the summer of 1932 six centers were established in various community centers on a volunteer basis. The success of these centers was so pronounced that in the fall of 1932 it was decided to establish some of them on a permanent basis.

The first problem to be considered was space and maintenance. The room space, light and heat, and janitor service are now provided free of charge by such agencies as the Division of Health, community social settlements, Associated Charities, and church organizations.

The matter of equipment was considered next. The Mayor's Committee on Recreation gave the centers a quantity of used toys, including a slide and sandbox, at the time the centers were opened in the summer. A public school sent a supply of toys to one of the centers. A storage warehouse company gave a piano to one of the centers. The Division of Health loaned a scale for the weighing of the children.

Financial aid and food contributions also have been received.

Service contributions are secured from volunteer workers, including nursery school instructors, nutritionists, doctors, dentists, and nurses. Carfare expenses of volunteers are met by the Association and the doctors, dentists, and some of the nurses receive a small honorarium for their services. The trained preschool instructors, one in charge of each center, are the only workers on a salary basis.

The preschool centers which are functioning now may be divided into three groups:

Group I. A center established some years ago at a Health District Station, which gives medical supervision, including examination, vaccination, immunization, and close follow-up work in the homes by nurses.

Group II. Four centers established by the Cleveland Child Health Association which offer a health and play program, including recreation, habit training, nutrition, medical and dental examinations, and follow-up work.

Group III. Three centers established by interested groups with whom the Cleveland Child Health Association cooperates in securing medical and dental examinations and in supplementing their nutrition program.

In Group II the children follow regular daily routines of free play, supervised play, toilet routine, mid-session lunch, and rest period. The supervised play includes rhythms, songs, games, story hour, rhymes, and simple handicraft. The centers are open for two and one-half hours daily, either morning or afternoon.

RECREATION AND HABIT TRAINING

The preschool instructor is interested not only in the physical aspects of the child, but in the mental and emotional as well. It is her purpose to try to give the child as ideal an atmosphere in which to develop as possible. She sets up daily routines for the children which are simple. For example, there is the daily toilet routine, during which the child learns to use the paper, flush the toilet, and wash and dry his hands. He does not always want to wash his hands; but he soon learns this must be done. After a short time he grows to like routines as they give him a sense of security. In fact certain procedures become so fixed that it is almost impossible to change them.

The children learn that when they play hard, they are too tired to enjoy a luncheon and so must rest before eating. The period may be from fifteen minutes to half an hour, depending on how hard they have been playing. During the rest period the worker can observe many difficulties such as thumb sucking, which can be overcome during the rest period by asking the child to put his hands behind his head.

When difficulties arise, the teacher tries to help the child meet and solve his own problems, rather than to solve them for him. She tries to answer all his questions satisfactorily and intelligently. In speaking she is careful not to use words which are above the child. The children are told the toys are in the center for everyone and must be shared; but when one child has a toy it is his until he drops it for another. They are allowed to make their own group rules. The worker tries to get the child to form his own opinions. If he does not agree with her, where possible, she lets him proceed and learn the result of his opinion.

Many of the children in the centers come from desolate homes. A pretty, neat room is essential to them, as it

gives a new outlook and instills in them the desire for the beautiful. The children in these centers learn the nursery rhymes and hear the stories and songs which are the right of all children but which are often denied to children of this economic group. They are given opportunities to express themselves through music and rhymes.

NUTRITION

Cod liver oil is given daily to the children during the winter months. The mid-session lunch has included milk, tomato juice, cream soups, cereals, crackers, whole wheat bread, and bananas and milk.

In connection with the lunches the teacher has the opportunity to teach table manners, politeness, etc. She does this not so much by telling the children what is proper as by doing the proper thing herself and allowing them to imitate her. During the lunches it is possible also to teach the children the value of certain foods and to interest the children in them.

A nutritionist weighs the children weekly and keeps individual graphs to show gain or loss in weight. She discusses food habits and menus with the mothers.

HEALTH SUPERVISION

Daily inspection is carried out to detect symptoms of illness, and all suspects are excluded. Attention is given to personal cleanliness, and instruction in health habits are inculcated in the daily program.

A quantity of tooth brushes were secured for the centers. A routine of brushing the teeth is carried on.

At stated intervals of about six months the children are given complete physical examinations, and yearly dental examinations. A public health nurse assists in these examinations and makes follow-up calls in the homes, referring cases for correction to private doctors

and dentists or to the proper dispensaries and clinics.

COST OF CENTERS

The average monthly expenditures are \$70 per center. On the basis of an average attendance of 20 children a day at a center, the cost per child is

\$3.50 a month or sixteen cents a day.

Social rating reports are secured for each child from the Social Service Clearing House of Cleveland. As the centers are free to the children attending, each child accepted is one who is or has recently been active at one of the recognized social service agencies.

REPORT OF AN EXPERIMENT DETERMINING THE EFFECT OF WEATHER ON CHILDREN'S SLEEP

THIS experiment was conducted by Eunice Pierce, who is one of the trained instructors at a preschool center of the Cleveland Child Health Association.

It was conducted in four nursery schools located in Cleveland—Western Reserve, Hanna, Mather, and Wade—and extended over a period of six months, in order to determine the effect of weather on the sleep of children.

The time the children went to sleep was tabulated and again the time they woke up, thus giving the actual length of the naps. The weather, temperature, and rain charts issued monthly by the government were used and correlated with the length of the sleep periods. Sixty-four children, thirty-two boys and thirty-two girls, were observed in the course of the experiment.

The results pointed to the following conclusions:

1. That the length of time children sleep is variable.

2. That weather affects the length of time children sleep.

3. That children sleep noticeably longer on rainy days.

4. That nap lengths drop tremendously on the first day of severe weather change, either hot or cold.

5. That the sleep tends to go back toward the normal if the extreme cold or hot level lasts for more than one day.

6. That boys as an average tend to sleep longer than girls.

7. That sleep falls off markedly preceding an illness.

8. That the 2 and 3-year olds do not sleep longer than the 4 and 5-year olds as an average.

9. That the sleep graphs of the children from different sections of the city followed much the same curves.

INDUSTRIAL HYGIENE

Psychrometer Has Two Wet Bulbs—Precise measurement of humidity from zero to nearly saturation, and at air temperatures up to 150° F., is possible with an improved psychrometer developed at the Bureau of Standards. Two wet bulbs are used in this instrument.

The wick which supplies water to the wet bulb passes through a perforated tube which serves as a first wet bulb of the instrument. The second wet bulb is of the ordinary type. By this means the water supply for the second wet bulb is pre-cooled to the evaporation temperature.

Tests covering the range of temperature from zero to 150° F. show that the precision of humidity measurement depends only on the precision of the thermometers used.—*Heating, Piping & Air Conditioning*, V, 4:206 (Apr.), 1933.

The Presence of Lead Dust and Fumes in the Air of Streets, Automobile Repair Shops, and Industrial Establishments of Large Cities—A survey to determine the amount of lead dust and fumes present in the air of city streets, automobile repair shops, and non-lead-using industrial establishments was made in 14 of the largest cities in the United States. The Greenburg-Smith Impinger apparatus was used as the air sampling instrument. An average volume of about 8 cubic meters of air at the breathing level was taken in each sample.

In all, 78 samples were analyzed; 25 in automobile repair shops, 28 in streets, and the remaining 25 in various types of industrial plants in which lead compounds were not handled. The air of automobile repair shops disclosed an

average of 0.13 mg. of lead per 10 cubic meters with a maximum of 1.11 mg. The average for the street samples was 0.09 with a maximum of 0.34, and the non-lead-using industries averaged 0.10 with a maximum of 0.35. Eighty-six per cent of all the samples in the three sampling places contained less than 0.2 mg. of lead in 10 cubic meters of air.—J. J. Bloomfield and H. S. Isbel, *J. Indust. Hyg.*, XV, 3:144-149 (Mar.), 1933.

L. G.

Safety Regulations for Refrigeration Equipment—The following safety regulations have been recommended by the authors in order to minimize hazards from automatic refrigeration equipment:

(1) The quantity of refrigerant in any one apparatus or system shall not exceed 20 lb.

(2) There shall be at all critical points pipes leading to the outside air and provided with fusible plugs which will open at temperatures in excess of 160° F., and thus permit the escape of the entire charge of refrigerant.—Yandell Henderson and Walter V. Babson, *J. Indust. Hyg.*, XV, 3:154-155 (Mar.), 1933.

L. G.

Noise in Heating and Air Conditioning: Where It Occurs and How It Is Prevented—In the practice of air conditioning and ventilation the engineer is often faced with the problem of designing and constructing a system practically free of noise. Such installations require care in the design of the individual parts of the installation. In some cases it is necessary to use special treatment in the construction of machinery foundations and it

may become desirable to treat the machinery room itself with noise absorbent material. The prevention of noise in the ducts may often be accomplished by proper fan selection, correct duct design, paying particular attention to air velocities obtained, and to the use of non-noise and vibration conducting connections at certain vital places in the system. Air baffles properly placed have considerable value in this connection.

This paper describes the use of one of the new noise measuring devices for the estimation of the noise produced at the air filters in a radio studio ventilation system when various arrangements of air filters were utilized. The paper does not provide a basis for broad conclusions in noise prevention but points out this valuable use of noise measuring device in the ventilating art.—Samuel R. Lewis, *Heating, Piping and Air Conditioning*, V, 4:198-199 (Apr.), 1933.

L. G.

The Effect of Viosterol on the Excretion of Lead—It is known that small doses of viosterol favor calcium deposition while larger doses of this substance favor calcium excretion. Since the metabolism of lead and of calcium are affected by the same influences, experiments designed to determine the effect of large doses of viosterol on lead excretion in cats were carried out.

In the first experiment six cats were each given 100 mg. of lead in the form of the acetate in 25 c.c. of milk daily for 49 days. The lead dosage was then discontinued for 21 days to permit deposition of lead in the bones. At the end of this period 3 cats were given 20 drops of viosterol daily in 25 c.c. of milk, while three others were used as controls. The viosterol cats were found to excrete about 10 times more lead than those of the control group.

In the second experiment six cats

were given 100 mg. of lead daily in the form of carbonate which was sprinkled on the food. This was continued for 21 days when two of the animals had convulsions and died. Lead administration to the remaining cats was discontinued for 10 days. At the end of this period feces were collected and analyzed for lead in 3-day periods. This 3-day sample was used as a control for lead excretion. Twenty drops of viosterol were then added to the diet in a small amount of milk at the end of the first 3-day period. The average daily excretion of lead per cat rose sharply after viosterol was begun and reached a peak in the fourth period when the amount of lead excreted per cat was 37 times greater than it had been in the control period.

The investigations suggest that viosterol may prove an acceptable form of therapy in cases of lead poisoning after exposure to lead has ceased.—Frederick B. Flinn and Adelaide Ross Smith, *J. Indust. Hyg.*, XV, 3:156-159 (May), 1933.

L. G.

Sulfur Dioxide in Pittsburgh Air—Sulfur dioxide determinations were made in the city of Pittsburgh as a part of the Mellon Institute's air pollution investigations. The results of the survey showed that the amount of sulfur dioxide present in Pittsburgh air is too small to cause concern from a hygienic standpoint. The average concentration of sulfur dioxide in 1932 was 0.14 parts per million.

It was found that the concentration of sulfur dioxide varied with the amount of fog in the atmosphere. On all days when the fog cleared by afternoon there was a corresponding sulfur dioxide decrease. On a day when the fog did not clear, the sulfur dioxide concentration was found to rise.—Carlisle Schade, *J. Indust. Hyg.*, XV, 3:150-153 (May), 1933.

The Roentgenological Aspects of Pneumoconiosis and Its Medico-Legal Aspects—In this article the authors question the wisdom of designating the appearance of pneumoconiosis by any term denoting numerical stages of progress and suggest the designation of the appearance by terms which imply their pathological nature. The following classification of silicotic appearances based upon known pathological changes has been suggested in place of the old numerical stages:

1. Peribronchial-perivascular-lymph node predominance. This may be rapid or slow, usually the latter.
2. Early interstitial predominance. This may be extremely or moderately rapid, depending upon the silica intake. It may or may not have an associated slight nodular appearance.
3. Advanced interstitial predominance.
4. Nodular predominance. Rapidly or slowly progressing.
5. Advanced diffuse or terminal fibrosis.
 - Conglomerate nodular type.
 - Interstitial type.
 - Massive fibrotic type.

The importance of roentgenology as a means of attack and defense in medico-legal questions in silicosis compensation cases is brought out. The creation of a competent Medical Board in each state is recommended in order to act on all claims for disability from pneumoconiosis. It would then be desirable to have each state pass compensation laws as nearly uniform in essential details as possible.—Henry K. Pancoast and Eugene P. Pendergrass, *J. Indust. Hyg.*, XV, 3:117-135 (May), 1933. L. G.

Toxicity of Osmium Tetroxide (Osmic Acid)—Metallic osmium is an entirely innocuous substance but when heated in air or oxygen, or acted upon by oxidizing agents, osmium tetroxide is readily formed. This highly volatile osmium tetroxide has been the

cause of numerous cases of severe poisoning.

Experimental work with white rabbits showed osmium tetroxide to be definitely toxic in concentrations of 250 mg., 500 mg., and 1 gm. in 190 liters of air. The time of exposure was 30 minutes. All of the animals succumbed. Those receiving 250 mg. survived for 4 days on an average, while the average survival time of those exposed to 1 gm. was but 30 hours.

The objective symptoms produced are the result of the action of irritant vapor on the exposed mucous surfaces and skin, upon the respiratory tract, and indirectly also on the kidneys. Autopsies showed the entire lung to be dark red with scattered irregular areas of purple. Dark discolorations were found on the epithelial lining of the bronchi and bronchioles. This staining was more marked in the trachea, the epiglottis, and the interior of the larynx, all of which were jet black.

The effect of osmium on the eyeball was also studied.

Protection from osmium tetroxide may be afforded by a reliable down-draft, preferably through a spray of 10 per cent sodium hydroxide to absorb the oxide. Where minute quantities are encountered, protection of the eyes by air-tight goggles is sufficient. In higher concentrations a mask with an "all service" canister affords an adequate safeguard.—F. R. Brunot, *J. Indust. Hyg.*, XV, 3:136-143 (May), 1933. L. G.

Obtaining Comfort Conditions by Controlled Radiation from Electrically Heated Walls—This investigation showed that by heating large surfaces such as the walls, ceiling or floor of a room to low temperatures (80-120° F.) comfort conditions may be maintained with relatively low air temperature (60° F.), thus resulting in a saving of heat. The power consump-

tion for the heating panels varied from 5.3 to 16.1 watts per square foot. A remarkably uniform temperature was found to prevail within the room as a result of the heating method presented.—L. W. Schade. Presented at the summer convention of the American Institute of Electrical Engineers, Chicago, Ill., June 26-30, 1933.

L. G.

Physiologic Changes During Exposure to Ionized Air—The influence of ionized air upon total metabolism, respiration, pulse rate, blood pressure and body temperature, was studied on human subjects under (a) basal conditions, (b) 2-4 hours after breakfast, and (c) 3-5 hours after a light lunch. Sixty persons in a total of 141 experiments were exposed for an hour or more to air containing from 5,000 to 1,500,000 small ions per cubic centimeter after a preliminary resting period of 1-2 hours in normal air.

The ionized air appeared to exert a normalizing influence upon the human mechanism by increasing or decreasing the physiologic processes under study.

The physiologic response to positive or negative ions did not differ greatly but certain differences were observed in the sensation produced by the two kinds of ions. The respiration of positive ions resulted in headaches and irritation of the nose and throat in some cases while negative ions predisposed to relaxation and other sensations of desirable character.—C. P. Yaglou, A. D. Brandt, and L. C. Benjamin. Presented at the Semi-Annual Meeting of the American Society of Heating and Ventilating Engineers, Detroit, Mich., June, 1933.

L. G.

Carbon Monoxide Distribution in Relation to the Heating and Ventilation of a One-Floor Garage—A study of the carbon monoxide distribution was made in a garage utilizing

various methods of ventilation. The air supply was made through large conical diffusers located near the ceiling for downward ventilation and located 4 inches above the floor level for upward ventilation.

The results showed that upward ventilation results in a lower concentration of carbon monoxide at the breathing line and a lower temperature above the breathing line than does downward ventilation.

Assuming the average rate of carbon monoxide production of an idling car to be 35 cubic feet per hour, an air change of 350,000 cubic feet per hour per car would be required to keep the carbon monoxide concentration down to one part in 10,000 parts of air.—F. C. Houghten and Paul McDermott. Presented at the Semi-Annual Meeting of the American Society of Heating and Ventilating Engineers, Detroit, Mich., June, 1933.

L. G.

The Application of the Eupatheoscope for Measuring the Performance of Direct Radiators and Convectors in Terms of Equivalent Temperature—The eupatheoscope, which is an instrument used as an index of the combined effects of air motion, radiation and convection, was used to determine whether the steam condensation of direct radiators and convectors could be correlated with the equivalent temperature as indicated by the eupatheoscope.

The study showed that the eupatheoscope served as a means of ranking various heating units in the order of the relative heating effects produced. The heating effect is not materially greater than the total heat output as measured by steam condensation under given standard conditions, and the authors feel that the practice of adding a large proportion to the condensation rating in order to provide for heating effect cannot be justified.—A. C. Willard, A. P.

Kratz, and N. K. Fahnestock. Presented at the Semi-Annual Meeting of the American Society of Heating and Ventilating Engineers, Detroit, Mich., June, 1933. L. G.

Necessity for Bureau of Occupational Diseases, Connecticut—Connecticut ranks third among the states in the percentage of her working population employed in manufacturing and mechanical industries. According to the 1930 Census, 309,465 persons, or 46 per cent of her working population, are so employed.

According to "Occupation Hazards and Diagnostic Signs," such workers are exposed to 700 hazardous occupations, some 500 of which are potentially dangerous to the health of the employees in Connecticut. The Bureau of Occupational Diseases has classified the hazardous materials, processes, and conditions into about 70 groups. At the same time, several thousand plants in the State were classified into about 100 industrial groups. This classification is so arranged that it may be correlated with that of the U. S. Census and of the National Council on Workmen's Compensation. The Bureau has made 1,373 field trips and 717 studies and surveys in various industries in the State (list attached). Each plant has received a confidential report of the Bureau's findings, including physical and chemical determinations of the working environment, with recommendations for the elimination or control of hazards found. Thus the health of several thousand workers was directly affected.

The report continues at some length with the conditions found; improvements noted; the centralization of information; industry's relationship to the industrial health problem, also that of the health department; the occupational disease program; the effect of industrial environment on health—in

which Dublin has shown that, age for age, the mortality rates of the industrial group run from one-and-a-half times to more than double the rates in non-hazardous occupations, and with a difference in life expectancy of seven years; occupational diseases vs. accidents, and the greater cost of the former; the necessity for control; the similarity to epidemics; the problem of new substances and processes; and essential control measures.

As it is the purpose of the State Department of Health to afford protection to all of the people of the State, the work of such a Bureau must be continued as an integral part of that duty. Forty-six per cent of the working population, embracing one-sixth of the population of the State, and representing a large income-producing portion, is not to be discriminated against and deprived of an essential protection. (Appendices attached.) — Connecticut State Department of Health (Hartford), 1933, 20 mimeographed pages plus Appendices. E. R. H.

Indices of Air Change and Air Distribution—The present ventilation code of the American Society of Heating and Ventilating Engineers makes use of the carbon dioxide content of the air of the environment under test as an index of air change. And variations in the CO₂ content as an index of air distribution. Realizing that human beings liberate heat and moisture in addition to CO₂, the authors of this paper have made a critical study of changes in air temperature, moisture content and CO₂ content in an effort to determine the most satisfactory index for future use.

Tests were conducted in a psychrometric chamber on 10 subjects. The calculated values of air change determined from CO₂ and moisture increase indicated a somewhat higher air change than that actually supplied by the ventilating system. The dis-

crepancies noted were not significant. The use of the dry-bulb temperature rise as an index is precluded because a large part of the liberated heat is absorbed by the surrounding walls and objects.

The determination of air change from the increase in moisture content is recommended because of the rapidity and simplicity of the method and because of the greater consistency shown in the determinations.

It is suggested that an air motion of from 20 to 50 ft. per minute, determined by the kata thermometer, be used as an index of satisfactory air distribution.—F. C. Houghten and J. L. Blackshaw, *Heating, Piping and Air Conditioning*, V, 6:324-330 (May), 1933. L. G.

Occupational Disease Compensation, Pennsylvania—The conclusions of the special Commission are first given, which were signed by all of its 10 members, composed of physicians, representatives of self-insurers, child health, underwriters, miners, and employers, with T. Henry Walnut, Philadelphia attorney, as chairman.

In brief, the Commission found that compensation for occupational diseases could be set up constitutionally; that a separate act would be required with its own rules for procedures; that special provisions were necessary to fit the slow development and course of occupational diseases; that assistance of scientists would be essential as well as a schedule listing of special diseases; that a general statement of the occupations concerned is also necessary; that definite articles should be drawn up to protect the fund as well as employers; that silicosis and/or miners' asthma would present the greatest difficulties in administrative problems; that a board of experts should therefore be appointed whose findings would be conclusive; that it would be impossible to estimate the cost of such a scheme accurately in

advance; that the wisdom of an occupational disease enactment was outside of the commission's pronouncement; and that a survey should be made by the U. S. Public Health Service of the exact nature and prevalence of chronic incapacitating miners' asthma.

Scope and cost, legal aspects, definitions, a survey of acts in other states, rules established by judicial decisions, reasons for omitting additional diseases from the suggested schedule, and recommendation that a medical board be set up as an integral part of the administrative body, are among the features further discussed. There is also a special report of the legal committee and of the committee on scope and cost, also much other material of coördinate value.—Pennsylvania Commission on Compensation for Industrial Disease to Governor Pinchot, Harrisburg), 1933, 96 pp. E. R. H.

Industrial Medicine in France—A Decree issued by the French Minister of Education on April 11, 1933, provides for the establishment of an Institute of Industrial Hygiene and Medicine at the Paris School of Medicine in place of the Industrial Hygiene Institute.

The object of the new foundation is to provide training in occupational hygiene and pathology for doctors who intend to practise in industry. It will contain a Hygiene Section, a Medical Section devoted to clinical study of occupational diseases, and a Toxicological Section.

The Institute will give instruction in the form of two introductory courses on industrial hygiene and industrial medicine, and an advanced course on industrial hygiene, medicine, and toxicology. In addition to lectures on theory, there will be opportunity for practical work, visits to factories, examination of workers; etc.—*Indust. & Labour Inf.*, XLVI, 7:177 (May 15), 1933. E. R. H.

Obituary—Sir Arthur Whitelegge—Benjamin Arthur Whitelegge died April 25, 1933, at the ripe age of 80 years. He was born in Tideswell, Derbyshire, graduated in medicine in 1876 from the University College, and was a member of the Council of the Royal Sanitary Institute with which he had been associated for over 50 years.

Dr. Whitelegge will be chiefly remembered by our readers as His Majesty's Chief (Medical) Inspector of Factories at the Home Office, which post he held from 1896 to 1917, in which latter year he was followed by Sir Thomas Legge. Under Whitelegge's leadership the Factory Department was greatly increased in both personnel and influence.

Considered a master of English, he was also the author of a compact textbook on Hygiene and Public Health which ran through 17 editions—the latter editions in co-authorship with Sir George Newman. Dr. Newman credits him with being "the man who established intimate relationship between the factory medical service and the public health service."—*J. Royal San. Inst.* (May), 1933, Supplement p. 198. Also a fine tribute (with portrait) by Sir George Newman in *Lancet*, V, 5723:990 (May 6), 1933. E. R. H.

Silicosis and Tuberculosis Among Miners of the Tri-State District of Oklahoma, Kansas, and Missouri—I.—This Report is for the year ending June 30, 1928, and is the first of a proposed series dealing with the data concerned. An earlier investigation, begun in 1923, by the U. S. Bureau of Mines and completed in 1925, showed less dust in the mines of this, the Picher district, than in the Joplin district, reported in 1915 (Technical Paper No. 105). The present investigation is the result of an agreement between the Metropolitan Life Insurance Company, the Bureau of Mines and the mining

companies. The first year's proceeds were expended in constructing and equipping the clinic.

Of 7,722 examined at Picher in the year ending June, 1928, 1,617 (21.3 per cent) were diagnosed as having silicosis; 267, silicosis plus tuberculosis; and 104, tuberculosis alone.

An analysis of examination-records, subjective symptoms, physical examinations, X-ray findings, prognosis and treatment of silicosis is given. Appendix I gives the technic of radiographic work; II, the symptoms of silicosis by stages; III, the pathology of silicosis, and IV, the Picher mining district, with map.

Prognosis in early silicosis is considered good if the patient can be removed from a dusty occupation and placed in the open, but advance of the disease, especially with the superaddition of tuberculosis, renders the outlook less favorable. In the Picher field, pneumonia is a frequent complication, from which the death rate is high. Treatment recommended is removal from the dust to "open air." For complicating tuberculosis, a high, dry, warm climate is recommended. The men do much better when they go to the Southwest.—R. R. Sayers, F. V. Meriwether, A. J. Lanza, and W. W. Adams, U. S. Bureau of Mines, Technical Paper 545, 1933, 30 pp. (illus.).

Paper No. II, for the year ending June 30, 1929, shows some reduction from the number of cases of silicosis found in the previous year, also in the number complicated with tuberculosis, but the number of cases of tuberculosis rose. Apparently, a total of 154 of the 2,110 essentially negative cases of the previous year had progressed to first-stage silicosis, 2 to first-stage silicosis plus tuberculosis, 10 to early tuberculosis, 1 to moderately advanced tuberculosis, and 1 to advanced tuberculosis. Similar progressions (figures given) was noted for others who were previously

reported in the early stages of silicosis.

The etiology of silicosis is discussed in relation to age, personal history, past history of diseases and defects, and of previous occupations. Subjective symptoms of the disease, and the findings of physical examinations, X-rays and laboratory, are also discussed in some detail.

The action of silica dust in the formation of fibrosis probably continues for 12 to 18 months provided a non-dusty occupation is sought and infection is avoided. Prevention at the mines is discussed, also removal to the high, dry climate of the Southwest. Patients do better with a limited amount of daily exercise.—F. V. Meriwether, R. R. Sayers, and A. J. Lanza, U. S. Bureau of Mines, Technical Paper No. 552, 1933, 28 pp.

E. R. H.

Occupational Disease Decisions—

1. A painter who sprays automobiles with wood alcohol in a small, poorly ventilated room and, as a result, suffers a disabling illness, is disabled, not by an occupational disease, but by an accidental personal injury, and under the Oklahoma workmen's compensation act is entitled to compensation.—*J.A.M.A. (Medicolegal)*, (June 3), 1933, p. 1894.

2. A laborer working under the direction of a county surveyor was overcome by smoke while burning brush along a country road. He applied for compensation for disability but died before the claim was considered. After investigation the claim was approved.—*Monitor, Ohio Indust. Comm.*, (June), 1933, p. 780.

3. An employee lifted one end of a gasoline engine weighing 300 pounds. He quit work immediately and the next day was operated upon for acute appendicitis. The claim for compensation was approved, the Commission holding that appendicitis can be brought

on by a strain or an injury to the right side of the abdomen.—*Monitor, Ohio Indust. Comm.*, (June), 1933, p. 780.

4. A painter ordered to paint a fence was compelled to tear away vines and shrubbery by which he came in contact with poison ivy. He was disabled for almost a month. His claim was allowed by the Commission as an injury claim.—*Monitor, Ohio Indust. Comm.*, (June), 1933, p. 780.

5. An employee carried sacks of stucco, weighing 100 pounds, up a flight of 22 steps. After carrying 8 such sacks he became dizzy and fell down the stairs. Two days later a physician found him suffering from acute cardiac dilation. His claim was considered meritorious and allowed.—*Monitor, Ohio Indust. Comm.*, (June), 1933, p. 781.

E. R. H.

Ventilation of Factories and Workshops—Conditions are stated for satisfactory ventilation including importance of air movement, cooling power, and the effects of impurities. The standards involve ventilation itself, air movement, temperature, and humidity.

Natural ventilation which pertains to every workroom, to some extent, requires efficient openings of adequate size and suitability (which are discussed and illustrated). Much space is next given to the use of fans with illustrations of the propeller, pressure, and circulating types.

Mechanical ventilation systems of the extraction, plenum and combined types are described and illustrated. There is a note upon heating and a brief description of the instruments and apparatus for ascertaining atmospheric conditions.—Great Britain, Home Office, Welfare Pamphlet No. 5, 2d Ed., 51 pp., 1933. Price 1s. (British Library of Information, 270 Madison Ave., New York.)

E. R. H.

FOOD AND NUTRITION

The Copper, Iron and Manganese Content of Fish—Twenty species of fresh water and salt water fish were used in the experiment. The average copper content of both the salt water and fresh water fish was about the same, or 2.5 mg. per kilo. of moist material. The sunfish showed the lowest average copper content (1.4 mg. per kilo. of moist material), while the ling was the highest (4.1 mg.). Salt water fish was found to contain approximately 12 per cent more iron than fresh water fish. Cod fish and sunfish showed the lowest amount of iron (3.4 mg. per kilo. of moist material) while ling showed the greatest amount (9.6 mg.). Fresh water fish contained more manganese than salt water fish. The various species of fish muscle contain about 0.1 mg. to 0.4 mg. per kilo. of moist material. Species of fish with dark colored tissue contain approximately 75 per cent more iron than the species with the light colored tissue.—Thomas B. Parks and Embree R. Rose, *J. Nutrition*, 6:95 (Jan.), 1933.

Vitamin G (B₂) in Fruits—A study was made of fresh apples, avocados, oranges, and pears for vitamin G. Young albino rats, 21 days old and weighing 35 to 40 gm., were placed in metal cages with raised screen floors, and given distilled water and a basal diet deficient in vitamin G. At the end of two weeks, each animal was given a daily weighed portion of the material to be tested in addition to the basal diet. The apples used were Arkansas grown Delicious. Experiments were also made with Washington grown Delicious but the results were similar to the former. Bartlett pears, California oranges and avocado (Fuerte

variety) were the other fruits tested. Apples and oranges were found to be poorer in vitamin G than such root vegetables as beets, carrots, potatoes, and turnips. Avocados and pears were found to be better sources of the vitamin than the root vegetables but poorer than the leafy ones. Oranges and apples each contained about one-fifth Bourquin-Sherman unit per gram of the fresh edible fruit; avocados contained about two-thirds unit per gram, while pears were found to contain one unit per gram.—Paul L. Day and William J. Darby, *J. Home Econ.*, 25: 319 (Apr.), 1933.

The Chemical Nature of Vitamin C—The authors here undertake to show that hexuronic acid itself and not a contaminant is responsible for the antiscorbutic activity. In accordance with recent chemical analysis, this term is dropped and for it "ascorbic acid" is substituted. Adrenal glands are the only materials suitable for large scale preparations of ascorbic acid. Owing to the difficulty in securing these, investigation was made of vegetable sources. One apparently has been found in the Hungarian red pepper, *Capsicum annuum*, which shows a high reducing power. A method is given for preparation of the ascorbic acid from these red peppers following which the authors finally obtained yellow crystals melting at 187 to 189°. Guinea pigs were protected against scurvy for 65 days with 0.5 mg. of this substance. On recrystallization, crystals were obtained melting sharply at 192°, the product corresponding to a pure preparation of ascorbic acid. In order to prove that contaminants were not responsible for the biological activity, a

derivative, monoacetone-ascorbic acid, was prepared. This monoacetone derivative is only partly protective but ascorbic acid recovered from the derivative is completely protective. The test with different substances for a 65 day period on 250 to 350 gm. animals showed full protection was secured with 1.5 c.c. lemon juice added to the basal diet and when the animals were given 1 mg. ascorbic acid prepared from the acetone derivative, or 0.5 mg. ascorbic acid prepared from the paprika. Very good results were also secured with 0.5 c.c. paprika juice, with 1 mg. monoacetone-ascorbic acid and with 0.5 mg. ascorbic acid, recrystallized five times, obtained from adrenal glands. In an experiment to determine the stores of ascorbic acid in the adrenal glands of animals, it was found that this rapidly disappears when the animals are on a vitamin C-free diet.—Joseph Louis Svirebely and Albert Szent-Györgyi, *Biochem. J.*, 27:279, 1933.

The Effect of Cooking on the Vitamin A and C Content of Fresh and Dried Apricots—This study involves the effect of cooking on the retention of vitamin C in dried fruits—peaches, prunes, and apricots—both sulfured and unsulfured, supplementing previous reports from this laboratory showing the protective value of sulfuring on vitamin C, and to a lesser extent, on vitamin A. The question was raised by Nelson and Jones of the U. S. Department of Agriculture, who, in unpublished work, observed that the effect of sulfuring would be of little practical value since cooking tended to destroy vitamin C. This experiment aims to answer two questions, the effect of cooking in the case of sulfured and unsulfured apricots and the effect of processing and re-sulfuring. The fruit was cooked by bringing the temperature to 85° C in 15 minutes and maintaining that temperature for 5 minutes.

The technique was that followed in previous experiments with a total feeding period of 60 days. Comparisons of the vitamin C content of the raw and cooked fresh apricots show in every instance that the raw product is much more antiscorbutic than the cooked, 15 gm. of the fresh raw apricot affording full protection against scurvy, as against more than 20 gm. for the cooked fresh fruit, indicating a probable loss of 30 to 50 per cent of the vitamin C through cooking.

Comparison was made between the raw and cooked, sulfured and sundried apricots, and the same fruit after storage at room temperature for one year and the unsulfured, sundried and dehydrated. In the case of the sulfured and sundried, there was a retention of 94 to 100 per cent of both raw and cooked. The same after a year's storage showed only 40 per cent retention. The raw, unsulfured, sundried and dehydrated showed no retention of vitamin C. Both raw and cooked, sulfured and sundried showed approximately a 50 per cent retention. In the storage experiment, there was a loss of 31 per cent of the sulfur dioxide as well as 60 per cent of its antiscorbutic value. After cooking there was a further loss of more than 50 per cent of the sulfur dioxide but no parallel loss of vitamin C.

Fifteen and 25 gm. respectively of the raw fresh and cooked fresh apricot are regarded as protective. Since the equivalent of 16 gm., either raw or cooked, in the case of sulfured fruit furnishes practically complete protection, it is concluded that the full vitamin value of the fresh apricot is retained. Sulfured apricots held at room temperature for 5 months and then commercially processed show a loss of approximately 50 per cent of vitamin C, as against practically no loss of this vitamin when stored at 0° C, showing that freezing storage is necessary to preserve vitamin C. In the case of

vitamin A, less variation is shown between the raw and cooked sulfured fruits. According to the results of the experiment, 26 to 41 per cent of vitamin A is preserved in the raw sulfured fruit, and 25 to 33 per cent in the same fruit cooked. Vitamin A is retained to the extent of 16 to 28 per cent in the raw unsulfured dried fruit, against 9 to 20 per cent, cooked. Again attention is called to the unusually high vitamin A content of apricots, which is attributed to their pigmentation by carotene, reported by Morgan and Madsen (*J. Nutrition*, 6:83 [Jan.], 1933—see following abstract). The fact that cooked fresh fruit shows a higher vitamin A value is attributed to better intestinal utilization either because of enzyme destruction or better carotene absorption. The calculated losses of vitamin A due to the drying process are 59 to 74 per cent in sulfured, 76 to 82 per cent in unsulfured, and 71 to 82 per cent in processed fruit.—Agnes Fay Morgan, Anna Field and P. F. Nichols, *J. Agr. Res.*, 46:841 (May 1), 1933.

Mottled Enamel Produced by Water Containing Sodium Fluoride—While McCollum and coworkers in 1925 reported the unusual growth of the upper incisors of rats fed sodium fluoride, credit is given to Smith, Lantz and Smith as the first to associate experimental fluorosis in the rat with the condition known as mottled enamel. A so-called "mottled enamel area" exists at Conway, S. C., and the municipal water supply has been shown to be high in fluorine—six parts per million. The object of this experiment was to compare the changes in the teeth of white rats fed small quantities of fluorine in the drinking water with those produced by natural water from a mottled enamel area. Experimental rats were placed on a leached casein and cornstarch diet supplemented with yeast, cod liver oil and salt mixture, the latter contributing

about 10 parts per million of fluorine to the diet. Groups of 6 rats were fed for about 100 days on this basal ration, the drinking water used in the various experiments being as follows:

Group 1, distilled water.

Group 2, municipal water supply of Conway, S. C., 10 times concentrated. This would make the fluorine content approximately 60 parts per million by the ferric chloride method of Churchill which was employed by the authors.

Group 3, synthetic water of the same composition as the concentrated Conway water except that it contained no fluorine.

Group 4, a similar synthetic water containing 150 p.p.m. of sodium fluoride (equivalent to about 68 p.p.m. of fluorine).

Group 5, distilled water plus 500 p.p.m. of sodium fluoride (equivalent to about 226 p.p.m. of fluorine).

Groups 1 and 3 (water containing no fluorine) grew normally and presented no evidence of disease. Teeth showed the normal orange color at all times. Groups 2 and 4 (water containing approximately 60 p.p.m. of fluorine, in the form of natural fluorine and added sodium fluoride, respectively) grew normally with the exception of the following gross pathological changes noted in the teeth: Within 10 days the normal orange color had disappeared from the labial surfaces of the lower incisors, which appeared whitish except for an opaque orange spot at the tip of each tooth. Within the next week they became a translucent white throughout. Within 52 days small brown spots appeared on the labial surfaces of these incisors. During the remainder of the feeding period these spots increased in number and gradually covered the entire surface of the teeth. Group 5 (distilled water containing 226 p.p.m. of fluorine as sodium fluoride) gained in weight 3 days, lost weight during the next week, and thereafter showed a more or less normal gain with the exception of one rat which died after 11 days' feeding. This experiment was

repeated with 20 rats and 16 of these died within 11 days, indicating that fluorine in these amounts has a distinct acute toxic effect. The surviving rats showed the same tooth changes as Groups 2 and 4, during the first 10 days but by the end of 52 days the teeth were chalky white and brittle and many of them had broken off at the tips or even at the gums, and the opposing teeth had become abnormally long, tending to curve upward and penetrate the palate.

The work confirms in general the conclusions of Smith, Lantz, and Smith that endemic tooth mottling is definitely due to fluorine in the drinking water. —W. H. Sebrell, H. T. Dean, E. Elvove, and R. P. Breaux, *Pub. Health Rep.*, 48:437 (April 28), 1933.

A Comparison of Apricots and Their Carotene Equivalent as Sources of Vitamin A—Royal apricots, having a deep yellow flesh, were chosen for the test. The carotene con-

tent of fresh frozen, sulfured sundried and unsulfured sundried apricots was determined by pyridine and by acetone ether extraction followed by colorimetric estimation. The fresh frozen apricots which were used for the vitamin tests were found to have a maximum of 0.102 mg. carotene per gram of fruit solids compared with 0.066 and 0.060 mg. for the sulfured and unsulfured samples, indicating losses of 36 and 41 per cent of the carotenoid values during drying. A daily dose of 15 mg. of the fresh fruit gave an increase of 3 gm. body weight per week. Twice the equivalent of this amount must be fed as either sulfured or unsulfured sundried apricots in order to obtain about the same amount of growth. In nearly all cases the unsulfured dried apricots yielded growth in proportion to carotene intake which was distinctly lower than the other sources of carotene used. —Agnes Fay Morgan and Evelyn O. Madsen, *J. Nutrition*, 6:83 (Jan.), 1933.

PUBLIC HEALTH NURSING*

Health Education Conference at Ann Arbor—The tone of the conference on health education, held at Ann Arbor under the auspices of the American Child Health Association, was definitely educational. There were no suggestions as to what the doctor or nurse as such should do, but what should be taught for the good of the child.

No one knows definitely yet what health education practices prove best for the child. There was much discussion pro and con as to the value of weighing and measuring school children and as to whether the school or community should be responsible for milk, hot lunches, filling children's teeth, etc. Some felt that unless an activity was purely educational (in some cases for demonstration, perhaps) it had no place in the budget of school authorities.

The question of the abiding values of Gold Star and Blue Ribbon Campaigns was argued again pro and con.

Health Education is rapidly changing from formal education to progressive education in which practice rather than theory is stressed. In assisting teachers, efforts are made first to have them develop a point of view, then to guide experience. The old conception of health education was to teach how to prevent sickness, now it is to promote healthful living. The content has been changed also: we used to give advice on what not to do, now we try to control the factors in the environment in which we live.

There was general agreement that there needs to be more research work done in the field of health education.

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

The League Meeting in Chicago—The National League of Nursing Education, which is composed of superintendents, instructors, supervisors, and all other nurses acting in a teaching capacity in nursing schools, held its 1933 annual meeting at the Drake Hotel in Chicago the week of June 19.

It was in 1893 at the World's Fair in Chicago that the League was formed under the original name of the American Society of Superintendents of Training Schools for Nurses and it seemed fitting that the 40th Anniversary of the League should be held at the time of the Century of Progress Exposition in Chicago.

It is significant that one whole day's program was devoted to a discussion of ways to improve obstetrical nursing. As a result of the discussion the American Nurses' Association and the League pledged themselves to make better obstetrical nursing a project for the coming year.

Another whole day of the program was devoted to a discussion of the need for psychiatric nursing. A map was displayed showing the distribution of graduate nurses in the psychiatric hospitals in the United States. Some states, like Minnesota and New York, made a good showing; others showed no trained nurses in any of the psychiatric hospitals.

One day of the League meeting was devoted to problems of state boards of nurse examiners.

One of the features of the program was the presentation of the Saunders Medal for distinguished service in nursing to Clara D. Noyes, R.N., National Director, American Red Cross Nursing Service, Washington, D. C., by

Dr. Malcolm T. MacEachern of the American College of Surgeons.

The N.O.P.H.N.—When the National Organization for Public Health Nursing was founded in 1912, there were fewer than 3,000 public health nurses in this country. Now there are approximately 20,000 and about 6,300 are members of the N.O.P.H.N. Every public health nurse in New Mexico is a member for 1933. Rhode Island comes next with an enrollment percentage of 96, District of Columbia ranks third with 87 per cent, Oklahoma and Iowa fourth and fifth with 72 and 69 per cent respectively. Michigan comes sixth with 68 per cent. Fourteen states are more than half enrolled and in half the states 40 per cent or more of the public health nurses are members of the Organization.

The N.O.P.H.N. is interesting because it is a national organization which includes both professional and lay-workers in its membership. The interest and support of a well informed citizen's group is considered to be an essential factor in the successful development of every public health nursing agency; it is this fact that accounts for the lay members.

In the list given below are recounted some of the accomplishments of the National Organization for Public Health Nursing during the past two years:

1. Published *Objectives of Public Health Nursing and Qualifications for Public Health Nurses for 1935*.

2. Prepared two books: a revised edition of the *Manual of Public Health Nursing and Principles and Practices of Public Health Nursing Including Cost Analysis*.

3. Took a "1931 Census of Public Health Nurses in the U. S. A."

4. Gave advisory and consultation service in the field in nearly all the states in the union.

5. Conducted social hygiene and tuberculosis institutes in over half the states and institutes for board members in more than a dozen states.

6. Published monthly the magazine *Public Health Nursing*, the only magazine in the world devoted solely to subjects related to public health nursing.

7. Maintained a vocational guidance and placement service in the Joint Vocational Service.

8. Gathered facts on the economic emergency which have been used to stabilize local public health nursing situations.

9. Carried on a nationwide correspondence of approximately 600 letters monthly.

10. Continued to recommend minimum requirements for post-graduate courses in public health nursing.

11. Conducted and published an annual public health nurse's salary study.

12. Offered special service to boards and committees through a lay staff member and, through her, also conducted an educational study program for them.

13. Prepared 13 bibliographies in relation to various aspects of public health nursing and made them available on request.

14. Continued to publish public health nursing record forms.

15. Continued the work of the School Nursing Section and published a special school nursing number of the magazine each September.

16. Continued the work of the Industrial Nursing Section and published material for industrial nurses; also prepared a book *Nursing in Industry* soon to be published.

17. Planned a survey of public health nursing throughout the country.

18. Developed and fostered relationships with many of the National Health Agencies in this country.

Listening In, N.O.P.H.N. Releases in June, 1932, and May, 1933.

EDUCATION AND PUBLICITY*

Health Education at Indianapolis—Elsewhere in the *Journal* you will find the outline of the Health Education Section's program for the October convention at Indianapolis.

Under the title, "Organization of Adult Groups for Health Education," the first session will deal with the problem of health teaching for those members of the adult population who do not belong to service clubs, parent-teacher associations, church societies and other groups already organized and ready to welcome speakers on health subjects. Those who most need health teaching are least likely to be members of these organized groups. They need the methods of a class, meeting in at least four or five sessions. How can they be found, brought together in groups and held together long enough to learn some of the elementary facts about health? The speakers in this session will tell of methods used in reaching this section of the public.

"Retailing Health Information and Ideas" makes another approach to the problem of how to put salt on the bird's tail. First catch your bird, but how? In this session the whole question of distribution within a single city will be discussed. How do you find your market for health education? How do you cover it? Three hypothetical campaigns are to be outlined, all of them requiring well planned and thorough distribution.

Are there certain objectives on which all health organizations and health departments can unite in what they tell

the public? Is it possible that the combined forces of the health agencies might bring about much stronger support for public health work? It is the aim of the panel session, in which six or seven leaders in public health will participate, to arrive at an agreement on one or more common objectives which might be made the basis for intensive health publicity during the coming year. Our joint session with the Vital Statistics Section will consider news values in statistics, with special attention to ways in which the significance of national statistics can be interpreted in relation to local situations.—Mary Swain Routzahn.

Again Education and Publicity Headquarters will be a feature of the Annual Meeting. Have you material for display? Have you ideas as to what should be displayed? Please write editor of this department.

A Century of Progress—Chicago has put on a splendid show. The strictly public health exhibits are few, but many other displays in the medical section of the Hall of Sciences will interest health workers. Here are some notes supplied by the exposition management:

The first X-ray photograph ever used in surgery—two months after the discovery was announced by Roentgen in 1895—is in the exhibit of the medical department of McGill University of Montreal, Canada, in the Medical Section of the science exhibits.

The display of the Medical Sciences visualizes the tremendous advance in the past century in the knowledge of the causes, detection, prevention and cure of human and animal diseases. Scientific medical institutions of England, France, Germany, Austria, Italy, Holland and Canada have cooperated with the American associations.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

The transparent Man, from the Deutsches Hygiene Museum of Dresden, Germany, is a life size model, of transparent cellon, the interior of which is illuminated to show in rotation all the deep organs of the body.

Also in this exhibit are moving models of parts of the body which may be operated by the visitor, showing the action of joints, operation of the breathing apparatus, circulation of the blood, the larynx in different states, and horizontal sections of the body, shown in a life size model in eight parts.

The works of Louis Pasteur, pioneer of bacteriology and of Robert Koch, who discovered the tubercle bacillus, are shown in commemorative exhibits.

Structure and function of the nervous system are demonstrated by the Central Institute for Brain Research of Amsterdam, Holland.

An extensive exhibit of work in bacteriology and tropical diseases of man and animals is that of the Wellcome Research Institution of London. The Institution shows models of the floating laboratory presented to the Sudan government on the Nile and of the mobile field laboratory given the British War Office during the World War.

Progress of hospitals in the past century in America is shown by the American College of Surgeons. The American Medical Association uses dioramas, mechanical displays and transparencies to show the evolution of medical care. The American Pharmaceutical Association illustrates the evolution of medicine dispensing from an old-time pharmacy to actual demonstrations of modern prescription compounding, assays and chemical tests.

History of blood transfusion is shown by the use of actual instruments in the exhibit of the Cleveland Clinic Foundation. Physiological relations of the thyroid, pituitary, suprarenal and sex glands are shown by specimens, models and charts.

The discovery of appendicitis in the last century is shown by Harvard University and the Massachusetts General Hospital. The development of abdominal surgery and work on the treatment of pernicious anaemia are among other subjects of exhibits.

Motion pictures, wax models, transparent photographs and charts are used by the Mayo Foundation to illustrate work on goitre, diseases of the digestive tract and of the nervous system. A large electric thermometer enables visitors to take the temperature of their hands and a thermometer enables them to test their nerve steadiness.

Rehabilitation of the crippled child is the subject of the University of Chicago exhibit. Motion pictures show results of work on

acute infantile paralysis. Models and photographs illustrate the possibilities of work on the spine.

The Georgia Warm Springs Foundation, for the study and treatment of infantile paralysis, founded and financed by President Franklin D. Roosevelt, exhibits photographs illustrating exercise and massage treatments for patients suffering from the results of the disease. A series of X-ray photographs of affected limbs show results of treatment.

Bright's disease is illustrated by specimens of organs and the relations between kidney disease and acute infections are shown by Marquette University and Milwaukee County Hospital.

The American Urological Association presents an exhibit on diseases of the urinary tract.

To demonstrate the fact that cancer is, to a great extent, curable if recognized and treated in early stages, is the purpose of the exhibits of the American Society for the Control of Cancer and of the New York City Cancer Committee. Influence of genetics on cancer is shown by the Otho S. A. Sprague Memorial Institute—University of Chicago—in records of 110,000 necropsies on mice in twenty-three years.

Importance of prenatal and post-natal care for babies is shown by the Maternity Association of New York. Questions and answers on maternal hygiene are shown by the Chicago Medical, Dental and Allied Service Women's Association.

The fight against tuberculosis is portrayed by the Chicago Municipal Tuberculosis Sanitarium and the Chicago Tuberculosis Institute.

Causes, prevention and treatment of rheumatism are shown by the American Committee for the Control of Rheumatism.

Care of the teeth and the progress of dental science are shown by the Chicago Centennial Dental Congress. Motion pictures, operating models, specimens, charts and transparencies are used to show methods of treatment and the relation of the teeth to the general health.

Relation of focal infections to systemic diseases is the subject of the exhibit of the University of Illinois and the Illinois Department of Public Health. The Chicago Board of Health shows the work for the control of preventable diseases in the city's past 100 years.

Loyola University, Chicago, shows a series of complete anatomical models. The University of Wisconsin presents the history of the pioneer work on gastric digestion, result of the observation 100 years ago of Alexis

St. Martin, whose digestive operations were visible as a result of a gunshot wound.

Health is represented in effective fashion in the social welfare section of the Hall of Social Sciences.

Public health and the medical sciences in general do not approach the German Hygiene Museum in graphic presentation. And in all the buildings we visited we noticed but a single use of the symbols or "fact-pictures" as developed so strikingly by Dr. Otto Neurath of the Social and Economic Museum, Vienna, for the presentation of statistical data.

Throughout the exposition light, color and form have been used to give settings for the displays, in addition to their large scale use outdoors in producing effects which delight the eye.

In the construction of scientific exhibits and those showing processes and products lavish use has been made of modern methods of graphic presentation. Many ideas may be taken over by the readers of the *Journal*, but naturally many of the forms used are possible because of funds available far beyond the resources of health and welfare agencies.

Much has been done to explain the exhibits to visitors. But largely the exhibitors overlooked the fairly recent studies which have been made in the museum field. And mere common sense would have bettered many exhibits in their audience contacts.

Typewritten labels were seen on elaborate, expensive scientific displays. Pages of *typewritten matter in capital letters* were seen. Signs, under glass, in small letters, all capitals, and above the eye level were used in an expensive commercial display.

Mechanical voices explained in many cases, but frequently the voice or the recording was not satisfactory. One of the successes was the easily recognized voice of Dr. W. W. Bauer in one of the

booths of the American Medical Association.

"Do you want to learn something about the exhibits?" or "Are there any questions I could answer?" was the unfortunate and rather futile way in which some of the human explainers approached visitors. If they had started telling some interesting fact or idea, and had pointed to the exhibit many of the visitors would have listened gladly. Few of the explainers had a pointer to hold the attention of visitors and to direct attention to the particular detail which was being discussed. Good explainers had audiences.

We hope that every delegate to the A.P.H.A. meeting at Indianapolis in October will be able to add at least a day at the Century of Progress.

What Have You?—Anything you have written or published, or have read which might be used in explaining the importance of any public health activity? Anything which other health agencies might use, or chests and federations which must soon face the enormous job of raising funds to keep going the non-official health activities in many cities?

Case stories, facts, statistics? Reports of studies which reveal situations or needs, or point to trends?

Anything about results?

Almost unlimited quantities of such material can be used during the next six months—in press releases, by magazine and syndicate writers, for bulletins to local agencies. And he helps most who helps quickly.

Address Miss Mabel Ellis, editor, United Educational Program, 130 East 22d Street, New York.

If you have something which should be mentioned in this department of the *Journal* please send a copy also to Evart G. Routzahn, 130 East 22d Street, New York.

Again Behind the Front Lines— Last year a series of bulletins, "Behind the Front Lines," was issued for those wanting fresh data for educational presentation of health and welfare work. Those bulletins were prepared first for use in the fall and winter money-raising campaigns. Then much of the material was used in the year round publicity of chests and individual agencies.

A new supplemental series is being prepared for issue in August. Four or five of the new series will present public health material. Any public or private agency may use the material, which is suitable for printed matter, house organs, newspaper copy, talks, etc.

The copy is prepared by the United Educational Program of the National Social Work Council. The bulletins are available for 10 cents a copy through Community Chests and Councils, Inc., Graybar Building, New York. Ask for a list.

Sixty Is the Limit—The 1933 Institute on Public Health Education will be held Saturday, Sunday and Monday, October 7-9, at Indianapolis. The general theme will be The Psychology of Health Education. Write the A.P.H.A. for details. Make sure that it will give what you want before signing up. Then you won't take the place of someone else.

Broadcasting in Manitoba—May 5, 1933, the 54th in a series of radio talks was given by representatives of the Manitoba Department of Health and Public Welfare. Some of the titles follow:

"The Place of Health in School Education"; "Child Health" (interview between a mother and her physician about underweight in children); "The Significance of the Common Cold"; "How Communicable Diseases Are Spread"; "The Aftermath of Communicable Diseases"; "The History of Vaccination and Preventive Inoculation";

"Common Skin Diseases"; "Maternal Welfare"; "A Christmas Well and Happy"; "Health Conditions in 1932" (a newspaper reporter interviews a health official); "The Scope and Aims of Mental Hygiene"; "Public Health Nursing Problems" (emergency conditions); "First Aid and Home Nursing" (a series of conversations between Ellen, an 8th grade girl, and her Aunt Mary, a nurse); "Scarlet Fever"; "Food Hygiene"; "Rural Sanitation"; "Sanitation and Housing"; "Vital Statistics" (series of three on their why and wherefore); "Diphtheria Prevention" (series of 3).

A full list and single copies are available. Address Anna E. Wells, Health Education Service, Department of Health and Public Welfare, Winnipeg, Manitoba.

Institute for Visual Education—Many of our readers know something about the method of graphic presentation developed by Dr. Otto Neurath in the Social and Economic Museum, Vienna. The method—

reduces complicated facts to their bare essentials and transforms them into pictures—attractive modern symbols which everyone can understand.

The Neurath method is based on the theory that it is better for the average man or woman to remember simplified pictures than to forget detailed and intricate figures. The Neurath fact-pictures are so clear and striking that they can be comprehended at a glance and are far more easily remembered than figures in type.

The Neurath charts have been widely used in Europe. American organizations, research workers and writers, however, have been seriously handicapped in using Dr. Neurath's method because of the difficulties and loss of time involved in ordering material from Vienna. An American agency is urgently called for which will make the Neurath technique applicable to American conditions, and charts readily available in this country.

An Organizing Committee for an Institute for Visual Education has been formed, and invites correspondence with those interested. Vital statistics are happily adapted to this striking form of presentation. Address Rudolf Modley, field secretary, 130 East 22d Street,

New York. Bertrand Brown of the Milbank Memorial Fund represents public health on the committee.

In the final organization we hope that a different name will be selected, since "visual education" means so much more in the school world in the United States than any single form of presentation of facts.

Health Examinations But a Part of a Whole—*The Health Examiner*, with the June, 1933, issue—

appears in a new form and under new auspices. Established in April, 1931, *The Health Examiner* has until the present been published by The Greater New York Committee on Health Examination. With this number the publication comes under the supervision of The New York Academy of Medicine, 2 East 103d St., New York City.

The events leading to the change in publication auspices reflect the growth of medical appreciation of the nature and significance of the health examination movement. *The Health Examiner* was created to propagate health examinations. Its first and early issues were devoted to the description of the technique in examining the apparently healthy individual. Many contributions from leaders of the medical profession were published, extolling the merits of the health examination. Some space and consideration were devoted to certain practical problems such as equipment, record keeping, follow-up, etc.

The editorial statement indicates a new approach to the health examination:

Time and accumulated experience, however, convinced the editorial board that the health examination idea could not effectively be promoted of and by itself. The examination of the apparently healthy individual is merely one phase of the practice of personal preventive medicine. Unless the health examination is made with this understanding, it is liable to prove an ineffective gesture, promising more than it could possibly achieve, and in the long run it would defeat the very ends at which it is aimed.

Dr. Iago Galdston, as a member of the editorial board, is largely responsible for the content of the magazine. Of considerable value to

many public health workers. \$1.00 a year; 10 cents a copy. Specimen copy free.

Emergency Relief Diet Demonstration—Already we have mentioned danger in demonstration of local relief diets, unless the public is informed as to the limitations in those diets. The *News Bulletin* of the Social Work Publicity Council, 130 East 22d Street, New York, refers to one attempt at public explanation:

In the April issue we gave the opinions of some social work leaders about the wisdom of drawing attention to relief food budgets by reporting formal dinners of campaign workers or other laymen where relief budget meals were served. You may judge for yourselves, therefore, the constructive value of the way the Cleveland News presented the Associated Charities' food budgets. A staff reporter and his family lived a week on the food a client would have, and the reporter wrote daily of their experience. The tone of the writing was light and readable, helped along by pictures of the family planning, preparing and consuming the meals. The conclusions seemed to be that it was not a great hardship for a week, but that even for that length of time it took careful planning. It is certainly well for the public to know what clients are expected to live on, and maybe this is one acceptable way for the realization to reach them.

Inner-Convention Interpretation—The strictly medical discussions in the annual meeting of the National Tuberculosis Association include the presentation of developments of much significance to the administrators of state and local tuberculosis associations. Many of the administrators are without medical training. All of them have a full-time job at the annual meeting in keeping up with the important sessions of the Sociological and Administrative Sections.

Near the close of the conference a special session was held for the non-medical delegates in which the significant utterances in the Pathological and Clinical Sections were reviewed.

The selecting and interpreting was done by Drs. Esmond R. Long and Iago Galdston. They were interesting and effective.

Health Material in Libraries— Have we given enough attention to health books and periodicals in public, school and other libraries—to the useful possibilities, and the dangers as well?

In "Social Hygiene and the Libraries," Pearl A. Winchester reports on a study made with the coöperation of public, school, state, normal school, medical school, and university libraries, including 22 in Canada.

The returns show a fairly generous number of books, with a rather high average in quality. The report gives considerable interesting detail as to the particular books found most widely in the different types of libraries.

Most widely distributed were titles by Wiggan, Darwin and Jane Addams, along with several titles from the list of selected books issued by American Social Hygiene Association.

The report discusses the problem of "closed shelves"; also subject headings for library catalogues. In *Journal of Social Hygiene*, 450 7th Avenue, New York. June, 1933. 35 cents.

HEALTH PLAYS

The *Bulletin* of the National Tuberculosis Association reports:

"Shadows," a health play by Mrs. Alice McGouldrick, Executive Secretary of the Maine Public Health Association, was recently published by that association and is available for distribution through their office, 256 Water Street, Augusta, Maine.

The play is well written and presents two contrasting scenes. The first scene is laid in 1882 and tells the story of a tuberculous family with the shadow of despair hanging over them before the discovery of the tubercle bacillus and modern public health organization. The second scene is in 1932 and takes place in the office of a public health nurse or tuberculosis association. It tells the story of

the modern organized campaign against tuberculosis. The play is simple in scenic requirements and could easily be presented by any local group, and may also be altered in the last scene to fit local conditions.

For the following address your state tuberculosis association:

"Thanks for Health Day," a playlet for grade, rural, private and parochial schools and "A Trip to Yesterday," a pageant for the high schools, are the titles of the two new programs which have been arranged for the schools of the nation for presentation on Thanksgiving Eve, Wednesday, November 29.

These two plays are offered in place of the school stories of former years and as a means of keeping in step with modern trends which call for dramatization of the story of the Seal. . . .

Both programs, which are timed for less than an hour, close with the distribution of bangle pins (small double barred crosses) and as the pupils receive their pins they will be asked to "tell two" (the 'tell two' pledge) people the story of the Seal as they have learned it through the program. . . .

Included with the "Thanks for Health Day" program is a list of ten class room activities and the whole is set up attractively in clip sheet style (all spread out on one sheet so that the teacher has only to cut it apart for the various assignments). A poster and bangle pins must accompany the clip sheet and two clip sheets are required for each teacher—one to cut up and one for copy.

HONORABLE MENTION

To National Society for the Prevention of Blindness, 450 7th Ave., New York City: for giving the addresses of all periodicals mentioned under "Current Articles of Interest," a department in *The Sight-Saving Review*, a quarterly magazine.

Health workers are too busy to go to a public library, where they may or may not locate the addresses of periodicals, copies of which they wish to order.

BOOKS AND REPORTS

Peace of Mind and Body—By *William S. Walsh, M.D.* New York: Dutton, 1933. 243 pp. Price, \$2.50.

Everyone desires peace of mind and body but its availability is determined mainly by the ability of individuals to live intelligently. Back of this is the necessity of health as a prerequisite to normal adjustment. All rules and regulations, plans and schemes for teaching people to manipulate their lives so that they may attain rational living appears dubitable in the light of the basic tendencies of mankind to magnify difficulties, to utilize leisure time without great thought and to stultify an individuality in the avid interest of attaining economic security.

Dr. Walsh suggests what is reasonable: the elimination of the disturbing environmental factors so that one may realize the joys of tranquillity. The attainment of such a state involves both physical and mental hygiene in the interest of physical vigor and vitality, personal satisfaction, useful and pleasant employment of all hours, whether in work, play or rest. The attainment of social adequacy assumes an important place in this scheme of organismic equilibrium.

Dr. Walsh is not a doctrinaire but his advice is based upon a number of factors which are beyond individual control. His approach involves a capacity for self-direction and intelligent self-guidance, which are not readily attainable. His mode of life calls for substantial courage, a splendid honesty with one's self in addition to a specialized knowledge of the essentials and art of living, which actually is the possession of comparatively few of our active population. To learn how to grow up, how to live in the home and

on the job, how to withstand pressures and how to enjoy the release into freedoms, how to measure one's own satisfactions, in terms of a practical standard of equability and equanimity is in itself a threat to the peace of mind unless the innate organization of the individual is equal to the task.

Peace of mind and body, after all, are by-products of living. General rules are difficult to follow. Everyone has personal problems to solve, out of which varying degrees of peace are attained. Sometimes life is merely an armed armistice, at other times it is retreat; and yet there is some peace to be found in each of these though perhaps to the onlooker it merely represents strife and discomfort. The goal of peace—pleasurable and persistent—warrants a battle.

Dr. Walsh has presented a non-technical, popular volume dealing with psychological values which are bound up in living, learning, and loving, intelligently, without losing emotional equilibrium.

IRA S. WILE

Child Care Today—By *Bela Schick, M.D., and William Rosenson, M.D.* New York: Greenberg, 1932. 320 pp. Price, \$2.50.

This is a well-written book by men of recognized ability, the facts being so simply stated that the subject matter is easily comprehended by the layman. It was felt by the authors that there was a distinct need for a book that would assist parents in laying the foundation for sound physical and mental health in infancy and childhood.

Part I deals with the important phases of prenatal care and influences.

Part II considers the details of general hygiene and feeding of infants.

There is an interesting chapter on "Guiding the Infant in His Intellectual and Emotional Growth."

Part III covers the preschool child—the child between 2 and 6 years of age—which has come to be called the "neglected age." The general care and hygiene of this child is well presented, with the newer ideas of nutrition and diet. There is a most important consideration of child guidance and behavior problems.

Part IV emphasizes disorders and diseases of childhood, especially from the preventive standpoint. Recognized procedures of prevention are fully considered and evaluated.

ELDRED V. THIEHOFF

The New Dentistry: A Phase of Preventive Medicine (Six Lowell Lectures)—By Leroy Matthew Simpson Miner, D.M.D., M.D. Cambridge: Harvard University Press, 1933. 219 pp. Price, \$2.00.

We would pass this book without review, except that it comes from the Harvard University Press, from which we are entitled to receive correct information, and it is written by the Dean of the Dental School of that University.

The lectures of which it is composed were delivered to the laity, and the book is intended for nonprofessional reading. It contains some useful information. We would, however, recommend both to the author and the editor of the Harvard University Press the use of a good medical dictionary, and a study of history, and would refer them particularly to Bulletin 19 of the Carnegie Foundation for the Advancement of Teaching, to the Dictionary of American Medical Biography by Kelly and Barrage, on Crawford W. Long, and the Index Catalogue of the Surgeon General's Library, Third Series, Vol. VII, page 764, Long (Crawford Williamson).

MAZÏCK P. RAVENEL, M.D.

Amateur Nurse—By Mary Wright Wheeler, R.N. Indianapolis: Bobbs-Merrill, 1933. 234 pp. Price, \$2.00.

This book will undoubtedly find a place among wives and mothers in average homes who sooner or later may be called upon to be amateur nurses. The style is informal and gay, sometimes even saucy. It is easy reading for laymen, because it is free of heavy scientific terms, and written in language for the "man in the street."

Obviously the book was not written by a public health nurse, because there is a little too much emphasis put on home medication, even though the doctor is mentioned in nearly every other paragraph. Argylol for a baby's inflamed eyes and to be swabbed on a sore throat, and "perles" of amyl nitrite for angina pectoris and asthma are illustrations of this.

Not all physicians will agree that the only place for the patient ill with pneumonia is the hospital. This disease does call for good care, but many cases have recovered at home with nursing furnished by members of one's own family, a practical nurse, a visiting nurse, or a private duty registered nurse. Some authorities feel that babies and very young children recover more rapidly and surely at home than in the hospital separated from parents and family.

The chapter on nursing care of prenatal patients is particularly good, but those that shine above all others are "The Amateur Nurse Lovingly Tends an Aged Invalid," "Tempting an Ailing Appetite," and "Good Invalids—Makings of and Encouragement to Be." Every trained as well as every amateur nurse should read these chapters. The author certainly knows her mental hygiene when dealing with elderly people. She could even give Dorothy Dix some pointers on how to solve the mother-in-law problem.

EVA F. MACDOUGALL

The Examination of Waters and Water Supplies—By John Clough Tresh, M.D., John Foster Beale, and Ernest Victor Suckling. (4th ed.) Philadelphia: Blakiston, 1933. 824 pp., 61 ill. Price, \$9.00.

The authors have tried to maintain the general plan of the first edition. With the greater utilization of sources of water, more emphasis has been placed upon the quality and purification of river waters. The most recent methods of sterilization of water by the use of minute amounts of silver and chloramine, for example, have been included. Sources of water, the mineral content, and the effect upon health of the various inorganic constituents are considered. Methods for the determination of the numerous elements in water are described and the properties of water which make it suitable or unfit for particular purposes are given.

Part IV is devoted to the interpretation of the results of physical, biological and chemical examinations. The lead solvent action of various waters and possible remedies are discussed, although this is of minor importance from the standpoint of readers in this country, where lead is only sparingly used as a conduit for drinking water.

A reasonable portion of the book is concerned with the bacteriological examination of water, the survival of bacteriological types, the enumeration, the use of different bacteriological indicators of sewage pollution, and the isolation and identification of pathogenic species. The last section deals with the purification and treatment of waters. Unfortunately, few data are given which might indicate the relative efficiency of different purification methods. A chapter on the treatment of water for the removal of undesirable odors and tastes will be of interest to many. This includes the use of activated carbon. The fundamentals of

swimming pool control are given in the final chapter. This is followed by 36 plates illustrating the microscopic organisms and debris found in waters derived from a variety of sources, and by an appendix which contains formulae for use in the chemical and bacteriological examinations of water and sewage.

The printing and make-up are excellent. NEWELL R. ZIEGLER

The Medical Secretary—By Minnie Genevieve Morse. New York: Macmillan, 1933. 162 pp. Price, \$1.50.

As one, who like the woman in the Bible, has suffered many things from many physicians, in the literary sense at least, the reviewer is tempted to indulge in enthusiasm over this little book, and would do so if it could be placed in the hands of all physicians as well as their secretaries, and they be made, in the words of the Episcopal Prayer Book, to "read, mark, learn, and inwardly digest" it.

The author writes from her experience of 10 years as a medical secretary, and 9 as a member of the executive staff of a general hospital, 3 of which included the training of young women for hospital record-room work. It is evident that she has made good use of her experience.

Short as the book is, it covers practically every point necessary, beginning with qualifications and personality desirable for secretarial work. She even considers such points as answering the telephone, a point the importance of which is probably not appreciated by many. Good advice concerning the handling of patients, and of correspondence, proper forms and style, etc., are given. Next comes advice on medical research, card indexing, abstracting of medical articles, and preparing of medical manuscripts, bibliographies, etc. Two pages are given to the signs used in correcting proof. A very useful section of the book, some 62 pages, is

devoted to medical terminology, which is remarkably complete for the space given, and correct.

There are only two things which we feel inclined to criticise: the definition of the prefix "meta," and the use of the word "receptionist," meaning the person who receives in the office. With such a rich language as English, there is hardly any excuse for coining such a terrible word.

The book is well printed and put together, and can be heartily recommended.

MAZÏCK P. RAVENEL

Die soziale Bedeutung und Beurteilung der Kreislauferkrankungen

—By Dr. Franz Grünbaum. Leipzig: Georg Thieme, 1933. 128 pp., 20 figs. in text. Price, M. 4.50.

This is No. 21 in the series of booklets on Labor and Health, a social-medical series from the Labor Ministry of Germany. This field of social-medical service has lagged behind others, notably those of tuberculosis, and of late of venereal diseases, infants' diseases, cripples, and cancer. The growth of information as to the significance, frequency, and the cause of diseases of the circulatory system has brought this field into prominence, especially in the United States. Mortality records in Germany from 1904 to 1928 show a sharp decline in total mortality and especially in that due to tuberculosis. On the other hand, deaths from heart disease have shown a statistical increase of about 60 per cent, rising most rapidly in recent years. A similar increase occurs in Massachusetts. Heart disease is, as a rule, the leading cause of death, being a little greater in most age classes in females than in males, and attaining its maximum incidence in sixty to seventy years, namely of 26.91 in males and 27.45 per cent in females in Prussia in 1928. There are suggestions that the increase in recent years is associated

somewhat with the growth of urban life, but the statistical data are as yet inadequate to make this certain. Organic heart diseases are clearly associated with rheumatic conditions in decreasing ratios in persons from ten to fifty years of age and with the incidence of infectious diseases, in increasing ratios, from forty to eighty years.

The social significance of this group of diseases is great, since they profoundly affect the amount and kind of labor that the persons thus afflicted can perform. They constitute a large element in the burden of invalidism which the family and society must carry.

C. A. KOFOID

Annual Report of the Bureau of Sanitary Engineering, Maryland State Dept. of Health, 1932.

It is interesting to report that the lowest typhoid fever death rate experienced in the history of the State of Maryland occurred this year when a death rate of 3 per 100,000 was reached, with virtually none of this attributable to public water supplies. \$7,071,000 were expended for water supply and sewerage facilities in the state or \$1,179,000 less than in 1931. Permits were issued for 143 of the 155 camps and for 8 of the 20 swimming pools inspected. Full-time sanitary engineering in Anne Arundel County permitted regular monthly sampling of all milk sold; special sampling from individual cows suspected of mastitis, garget and inflamed udders; careful investigations at 45 dairy farms, and inspections of all schools in the county. Improvements have been made at many of the dairies and schools.

Two epidemics of importance received special study. A para-typhoid A fever outbreak in a mining community at Vindex developed serious proportions in the late summer and, during a picnic at Fairview Beach, a severe epidemic of intestinal disturbance occurred. By

means of the salt test it was demonstrated that a suspected privy was the source of contamination of a semi-private dug well used as a source of water supply by the community. The well was inadequately protected against surface and underground drainage. A dug well furnishing drinking water for the public at Fairview Beach was not so definitely established as the cause of this epidemic, but it was so constructed as to be exposed to pollution from surface wash and probably shallow infiltration.

Developments in swimming pool sanitation and control consisted essentially in prescribing for the control of ringworm or athlete's foot. Cleansing of equipment with calcium hypochlorite and foot baths containing either a 2 per cent solution of calcium hypochlorite or a 15 per cent solution of sodium thiosulphate has been suggested, although the dechlorinating possibilities of the latter have made its use somewhat undesirable.

Early in the year, a report was prepared on the operation of sewage treatment plants at state institutions, based upon inspections and analyses of samples collected during 1930 and 1931.

The industrial waste that offered the important problem of the year was that from milk plants. This industry, without efficient regulation and control of supply and demand, was forced in several instances to discharge tons of skimmed milk containing valuable food and fertilizer elements into sewage treatment works and streams.

The recommendations of the Chief Engineer were accepted by Baltimore City in its refuse collection and disposal problem, and resulted in the construction of a new 600 ton incinerator which is to become city property at the expiration of the 10-year contract, and will save the city \$324,400 annually.

The Water Resources Commission

completed its survey and recommends the creation of a permanent Water Resources Commission of Maryland.

A. W. BLOHM

Social Work and Educational Problems in Germany—Series I, of 6 numbers of 10 mimeographed pages each, on present conditions in Germany, by Dr. Ruth Weiland, Manager of the Deutsche Zentrale fuer freie Jugendwohlfahrt (Central Organization for Youth Welfare), Berlin, Germany. \$3.00 U. S. currency. Schwarzburg Allee 3, Berlin-Charlottenburg, Germany.

This series of informative monographs will present to the English and American readers material difficult to obtain except from those actually engaged in active welfare work in Germany. The author has been in such work for a number of years and is conversant with the current trends in the social, economic and cultural life in that country. Her practical experience as an executive in the central organization for the youth welfare movement in Germany qualifies her in presenting the results of her observations. These papers discuss the following subjects:

1. Federal and State Legislation in the Field of Child Welfare
2. Responsibility of Local Authorities for Needy Individuals
3. Importance of Sickness, Invalid and Old Age Insurance for the Economically Weak
4. Welfare in Actual Practice for the Unemployed
5. Development and Extent of Social Welfare in Country Districts
6. Effects of Unemployment on Delinquency of Children and Young People

The first number of this series appears in May and will be followed soon by the others. All those who wish to gain a broad view of what is happening in the social welfare field in Germany will do well to read this series.

RICHARD A. BOLT

American Red Cross First Aid Text-Book—*Philadelphia: Blakiston, 1933. 237 pp., 110 illustrations. Price, paper, \$.60, cloth, \$1.00.*

This book is to be used by the teacher for the instruction of First Aid Classes, and it would be hard to conceive of a text that is more complete or more compact. There is not a superfluous word in it. Everything from corns to hiccoughs and hives is discussed from the first aid point of view.

Plenty of space is given to the 3 chief causes of accidents in the home; burns, falls and poisons. An innovation is rules for the prevention of these accidents given along with their first aid treatment.

The illustrations are abundant, up to date and excellent. The book deserves to be the leading authority in the field for its purpose—to guide instructors of First Aid Classes. It is also undoubtedly the best general reference book on first aid that exists.

EVA F. MACDOUGALL

Official Proceedings of the Thirty-Eighth Annual Convention of the American Society of Municipal Engineers—*St. Louis: Printed by the Society, 1933. 685 pp. Price, \$7.50.*

This volume of papers and discussions by well known authorities contains 3 chapters of particular interest from the public health standpoint, for they have to do with water supplies, refuse disposal, street cleaning, and sewage disposal. Other chapters contain matter of more or less health interest.

The chapter on water-works is a committee report on recent progress in producing pure water. Most municipal supplies are safe most of the time, and a large percentage of the typhoid which occurs could be prevented if more attention were given to the protection of the water after it has come into the

control of the company or municipality.

Cross connection with polluted water, leakage of well casings and conduits, and failure to chlorinate continuously are sources of danger which are now receiving more attention than formerly.

All recent filtration plants have been of the rapid, or mechanical, type. The only large cities on the Great Lakes without filters are Chicago and Milwaukee, and both are considering purification.

The removal of tastes and odors from water by activated carbon is being practised at over 400 municipal plants, at an average cost of 1 cent per 10,000 gallons.

There are 175 municipal water softening plants in the United States, of which about one-third treat well waters. Usually, the saving in soap justifies the cost.

Refuse disposal and street cleaning have recently been the subject of sharp budgetary cuts, but in spite of this there has been no great reduction in the work done. The savings have been made chiefly by wage reductions, stagger employment, speeding up, and increased mechanization.

Incineration, hog feeding and dumping are the usual methods employed for disposal of garbage. In the year ended June 30, 1932, there were 17 incinerators of from 50 to 600 tons daily capacity built in the United States. A number of incinerators were erected for the screenings produced by sewage disposal plants.

Closed vehicles with low-loading sides have made their appearance in a number of American cities for collecting refuse, and a number of designs have recently come upon the market; but aside from this no special advance in public cleansing methods or equipment is noted.

An excellent paper by Major I. S. Osborn, with discussions by a number of qualified persons, deals with the tech-

nical aspects of incinerator design. Others were on recent developments in sewerage and sewage disposal, by Albert P. Learned; on construction costs of sewage treatment works, by Samuel A. Greeley; on operation of sewage treatment works, by Harry A. Beaumont; and on modern methods of dewatering sludge, by Edmund B. Besseilievre.

These papers were read January 16-18, and the *Proceedings* published on April 1, an example of prompt, enterprising executive ability which many other societies might well imitate. Its early appearance adds immensely to the value of the volume.

GEORGE A. SOPER

Towards Mental Health: The Schizophrenic Problem—By Chas. Macfie Campbell. Cambridge: Harvard University Press, 1933. 110 pp. Price, \$1.25.

Dr. Campbell is a psychiatrist of wide experience and broad horizons. He offers a wealth of material, succinctly discussed, pointedly presented in a manner that should stimulate all readers who are interested in public health.

There is a clear demonstration of the difference between the fields of physical and mental hygiene. The larger measure of etiological certainty that obtains in promoting immunity from diphtheria sharply contrasts with the poorly formulated factors operating in the field of mental disorder.

Workers in public health must learn to perceive the significance of the reaction to living in its influence upon human happiness. Functional qualities of life are bound up in the complex problems of mental hygiene rather than the quantitative factors of vitality, which form the major phases of public health service.

Dr. Campbell selected the schizophrenic field rather than the subject of dementia praecox, thus indicating his

appreciation of the limitations of nomenclature and the uncertainty of much of our present day symptomatology as the basis of final diagnosis. His "schizophrenic territory" especially concerns public health authorities, because those living therein are most likely to become social liabilities.

Forty-three cases are discussed in terms of their reaction types. His exposition centers upon 3 main phases which recur most frequently in clinical histories: (1) the question of an adjustment in terms of the sex instinct and the memories of past sexual experience; (2) the problem of parent-sibling relationships, (3) the question of attaining an individual personal value in social groups.

The third chapter discusses heredity and environment and places the main emphasis upon education and environmental factors, because of the very limitations of hereditary material. Just as in public health work there was need for social coöperation and support in order to prevent tuberculosis, so the prevention of mental disorders calls for the education of individuals, families and communities.

Rigid community standards and demands for conformities tend to lessen mental stability and need curbing. Educational values enable each person to accept his real limitations and to function in terms of his complete organic potentials.

This is a presentation of the three Adolph Gehrmann lectures in hygiene given at the University of Illinois College of Medicine in 1932. The issues discussed, the cases presented and the viewpoints expressed are of paramount importance and merit reading and consideration by public health workers who have not yet appreciated the significance of individual adaptation as a factor in public achievement and communal welfare.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Diabetes in Married Women and "Maiden Ladies"—Among New Yorkers over 45 years, the diabetes death rate in single women is no higher than in bachelors, but the rate in married and widowed women is more than double that of married men. Is this due to the fact that married women are fatter than single, or because they have borne children? Other statisticians are invited to analyze their records to find out if the number of pregnancies affects the rate.

ANON. Diabetes in Older Adults by Civil Condition and Sex. *Quart. Bull. (New York City Dept. of Health)*, 1, 2:29 (June), 1933.

General Protection from Specific Immunization—Here are significant findings:

"1. . . . exercise of the defense mechanism by inoculation with heterologous antigens increases the resistance . . . to the subsequent action of various infectious agents and toxin substances.

2. . . . "this increased resistance . . . is the result of a mobilization, strengthening, and training of the defense mechanism.

3. . . . "it may be sufficient to modify the cause of subsequent infections . . . such as poliomyelitis or post-vaccinal encephalitis.

4. . . . "specific immunization . . . may be valuable in increasing resistance to various subsequent infections."

ARMSTRONG, C., and HARRISON, W. T. Heterologous Experience (Immunization) as a Factor in Resistance to Disease. *Pub. Health Rep.* 48, 22:597 (June 2), 1933.

Phage Proves a Weak Reed in Water Purification—Reasons why bacteriophage cannot be expected to be a useful agent in the purification of

polluted waters are briefly set forth. The studies reviewed indicate that many research workers have been led to believe in the sanitary value of the phage.

BEARD, P. J. Rôle of Bacteriophage in Natural Purification. *J. Infect. Dis.* 52, 3:420 (May-June), 1933.

Looking at Mortality Rates—There is no evidence in the Massachusetts death rates, conclude the authors, that the physically unfit are coddled in childhood, for the mortality rates in middle life, which should increase if we were rearing a race of weaklings, do in fact show a gratifying decline.

BIGELOW, G. H., and HAMBLIN, A. D. What Are Death Rates in Massachusetts Doing? *New Eng. J. Med.* 208, 25:1313 (June 22), 1933.

Blood Cultures from Rheumatic Fever—This is the brief and disturbing conclusion to a very long and involved dissertation on rheumatic fever: "Diplostreptococci (alpha type) and pleomorphic bacilli may be recovered repeatedly from the blood of patients (and others). . . . These organisms apparently represent stages in the life cycle of the same organism. A specific etiologic relationship between these organisms and rheumatic fever is questioned."

CALLOW, B. R. Bacteriologic Investigation of the Blood of Rheumatic Fever. *J. Infect. Dis.* 52, 3:279 (May-June), 1933.

Why We Fail to Detect Tuberculosis—Principal reasons for failure to diagnose tuberculosis early are that symptoms are absent and the doctor is not consulted. When he is, too much dependence is placed upon physi-

cal examination. History of contact is of some slight diagnostic value in children but not in adults. A roentgenogram is the only way to avoid mistakes. A tuberculin test should be given to all children and some adults.

CHADWICK, H. D. Early Detection of Pulmonary Tuberculosis. *New York State J. Med.* 203, 22:1143 (June 1), 1933.

Diphtheria Immunization and Tuberculosis—Schick positive children suffering from tuberculosis were immunized successfully against diphtheria with three injections of toxoid and without troublesome reactions.

PARISH, H. J. Immunization of Tuberculous Children Against Diphtheria with Formol Toxoid. *Lancet* 224, 5725:1063 (May 20), 1933.

Disposing of Sewage Sludge—The newer developments in the 57 varieties of sludge treatment found the country over are summarized in an inclusive discussion of this most difficult phase of sewage disposal. The authors conclude that sludge handling has not kept pace with other advances in sewage treatment.

RUDOLFS, W., and CLEARY, E. J. Sludge Disposal and Future Trends. *Sewage Works J.* 5, 3:409 (May), 1933.

Nursing Service and Relief—How the New York State Relief agency supplied nursing care for dependent families, utilizing the services of nurses who themselves needed aid, furnishes an important chapter in the story of better health administration.

SHEAHAN, M. W. An Experiment in Double Relief. *Pub. Health Nurs.* 25, 7:378 (July), 1933.

Successful Results from a Scarlet Fever Toxoid—A method is described for the concentration of scarlatinal streptococcus toxin to increase the content fourfold without increasing total nitrogen. Detoxification methods are given. Three doses administered to

children under 15 years produced only mild symptoms and induced a Dick negative condition in 87 per cent of the cases.

VELDEE, M. V. The Preparation of a Scarlet Fever Streptococcus Toxoid and Its Use in Active Immunization. *Canad. Pub. H. J.* 24, 6:255 (June), 1933.

Industrial Hygienists, Take Note—Methylene blue, an antidote for cyanide, is not a satisfactory one for carbon monoxide. Evidence is presented showing that its use may induce fatalities that might otherwise not occur.

HAGGARD, H. W., and GREENBURG, L. A. Methylene Blue, a Synergist, Not an Antidote, for Carbon Monoxide. *J.A.M.A.* 100, 25:2091 (June 24), 1933.

Contaminated Eclairs Poison 150 Women—Golden staphylococcus colonies isolated from eclair filler were cultured and the filtrate fed to volunteers. Symptoms of food poisoning developed quickly to prove that the eclairs were the culprits causing a large outbreak of digestive disorders. The volunteers who took the filtrate ought to be given a niche in the hall of public health fame. How the virulent staphylococcus got into the filler and from whence it came were not disclosed.

McBURNEY, R. Food Poisoning Due to Staphylococci. *J.A.M.A.* 100, 25:1999 (June 24), 1933.

Can Venereal Disease Cases Really Be Followed?—Services of a social worker were offered to a group of practicing physicians for the follow-up of delinquent venereal patients and sources of infection. What the outcome was, and the philosophic discussion of the possibilities of this line of attack, will interest all health officials who have the fortitude to look this problem in the eye.

NELSON, N. A. The Follow-Up of Gonorrhea and Syphilis in Private Practice. *New Eng. J. Med.* 203, 22:1153 (June 1), 1933.

NEWS FROM THE FIELD

DR. CHARLES PORTER.

PRESIDENT OF THE SOCIETY OF MEDICAL
OFFICERS OF HEALTH

AT a general meeting of the Society of Medical Officers of Health, held recently, Dr. Charles Porter, M.D., C.M., B.Sc. (P.H.) Edin., M.R.C.P. Edin., Barrister-at-Law, the well known Medical Officer of Health of the Metropolitan Borough of St. Marylebone, London, was unanimously elected President of the Society for the session 1933-34, and will take office on October 1st next. Dr. Porter, who is Deputy Chairman of the Council of the Royal Sanitary Institute, of England, is widely known for his active and whole-hearted support in connection with furthering the efforts of a number of societies whose aim and object it is to continue to raise the standard of the

health of the community. He is author and part-author of a number of works which are regarded as standard authorities upon the subjects dealt with. He is an ideal chairman of meetings and, socially, his personality has made him a host of friends, who will congratulate him upon his fresh honor. To these congratulations we add our own.

FINANCING PUBLIC IMPROVEMENTS

THE Industrial Recovery Act, passed by Congress June 13, 1933 (Act H. R. 5755), includes an appropriation of \$3,300,000,000 to finance public improvements. It is stated that under the provisions of the Act there is a possibility for local communities to secure necessary public improvements, such as sanitary water system, sewage systems, etc. This would indicate the possibility of securing necessary public health improvements under the provisions of the Public Works Title of the Industrial Recovery Act.

IMMUNIZATION PROGRAM FOR DENVER

RECOMMENDATIONS framed by the committee on relations with public schools of the Medical Society of the City and County of Denver have been adopted by welfare agencies as the basis of a program of immunization for the city and county. Provision was made for vaccination of all new-born infants occupying free beds at the Denver General and Colorado General hospitals and immunizations against both smallpox and diphtheria for all infants admitted to welfare stations. Free immunization of school children in poor districts and of poor children in other districts if certified by the school

nurse was recommended. Parents are to be urged to have their children immunized by the family physician.

The committee also recommended that the society sponsor a campaign of education among physicians to prepare them for the work of immunization, including demonstrations of the technic of giving toxoid, the Schick test, and smallpox vaccination. In addition, literature on immunization, prepared jointly by the society, the city health department and the school health authorities, will be distributed among parents' organizations, especially if a case of smallpox or diphtheria appears in the schools.

CANADIAN PUBLIC HEALTH MEETING

THE 22nd Annual Meeting of the Canadian Public Health Association was held in St. John, N. B., June 19, 20, and 21. There were two General Sessions, two meetings of the Vital Statistics section, and one each of the sections on Public Health Nursing and Laboratory. All were well attended.

Dr. John A. Ferrell, President of the American Public Health Association, attended the meeting and extended the greetings of the A.P.H.A.

Dr. William Warwick, Deputy Minister of Health of New Brunswick, is President of the Canadian Public Health Association for 1933, and Dr. Alphonse Lessard, Provincial Health Officer of the Province of Quebec, was named as President-Elect, to serve through the year 1934.

MISSOURI STATE BOARD OF HEALTH ABOLISHED

THE State Department of Health of Missouri has been created to supplant the old state board of health, through the enactment of recent legislation. The position of secretary of the board has been abolished and provisions have been made for the appoint-

ment of a commissioner of health, to whom have been transferred all rights, powers and duties heretofore conferred on the secretary. Emmett P. North, of St. Louis, is president.

CELEBRATION OF BIRTH OF BERNARDINO RAMAZZINI

DR. LUIGI DEVOTO, President of the Permanent International Commission on Labor Medicine, announces that the 3rd Centennial Anniversary of the birth of Bernardino Ramazzini will be celebrated on October 4, 1933, at the Clinica del Lavoro, Milan, Italy. Two editions of Ramazzini's "De Morbis Artificum" will be published for the occasion, one in Italian and one in French. Appropriate auxiliary features, exhibits, etc., will accompany. Those who may be able to attend should address Dr. Emery R. Hayhurst, 1108 State Office Building, Columbus, Ohio (representing the United States on the Commission).

INDIANA STATE HEALTH DEPARTMENT NEWS

DR. V. K. HARVEY is the new head of the Indiana State Department, succeeding Dr. John H. Hare. Dr. Harvey was formerly with the Department for two years as Epidemiologist, after which time he was given leave of absence to take a year in Johns Hopkins.

BIRTH CONTROL REVIEW SUSPENDS PUBLICATION

AFTER sixteen years, the *Birth Control Review*, published by the American Birth Control League, Inc., of New York, will be discontinued, with the July issue.

In its place, the League will issue a monthly news bulletin, which will start publication in October, and retain the name *Birth Control Review*.

CLOSING DATE FOR SUBMISSION OF FELLOWSHIP APPLICATIONS

ALL members desirous of applying for Fellowship are hereby advised that their applications must be transmitted to the Executive Office not later than August 10, if they are to be finally acted upon by the Governing Council at the Indianapolis Annual Meeting.

ORGANIZATIONS MEETING WITH US AT INDIANAPOLIS

The organizations meeting at Indianapolis with the American Public Health Association are scheduled as follows:

- October 7-9, Conference of State Sanitary Engineers.
- October 7-9, Public Health Education Institute (Claypool Hotel).
- October 9-12, International Association of Medical Health Officers.
- October 9-12, American Association of School Physicians (Severin Hotel).
- October 12-14, American Social Hygiene Association.
- October 12, Central States Sewage Works Association.
- October 12-14, International Association of Dairy and Milk Inspectors (Claypool Hotel).
- October 12-14, Indiana State Nurses' Association (Severin Hotel).
- October 12-14, Board of Directors of the Midwest Division, American Nurses' Association (Severin Hotel).

PERSONALS

DR. JAMES V. MAY, member A.P.H.A., was elected recently as President of the New England Society of Psychiatry.

EDWARD L. MILOSLAVICH, M.D., Fellow and applicant for Life Membership in the A.P.H.A., has accepted a position as Professor of Legal Medicine and Director of the Medico-

Legal Institute at the Royal University, Zagreb, Yugoslavia.

DR. OSCAR D. LUDWIG, member A.P.H.A., has been appointed Health Officer of Marion County, Ind., to fill the unexpired term of the late Dr. Frederick W. Mayer, of Indianapolis.

DR. ELMER T. MCGAUGH, of Jefferson City, Mo., has been appointed to serve as Missouri State Health Commissioner for a term of 4 years, succeeding Dr. James Stewart, who also acted as secretary.

DR. BURTON K. KILBOURNE, of Fargo, N. Dak., was elected president at the annual meeting of the official organization for North Dakota Health Officers, at Fargo recently. Dr. Ernst G. Sasse, of Lidgerwood, also member of the A.P.H.A., was elected vice-president; and Dr. Arthur A. Whittemore, of Bismarck, was elected secretary.

DRS. JOHN S. MCCELVEY, of Temple, Tex., and SAMUEL A. WOODWARD, of Fort Worth, have been appointed to the Texas State Board of Health, it is reported. Dr. John R. Mahone, of Austin, was recently named Health Officer of Cameron County, to succeed Dr. William E. Spivey, of San Benito.

DR. JOHN A. AMYOT, member A.P.H.A., for 14 years Deputy Minister of National Health of Canada, and, recently of Pensions and National Health, has retired because of ill health. From 1900 to 1919 he was associated with the Provincial Department of Health of Ontario and also with the public health teaching staff at the University of Toronto.

DR. HAVEN EMERSON, of New York, Life Member and President-Elect of the A.P.H.A., addressed the graduating class of the Woman's Medical College of Pennsylvania at the 81st annual commencement, June 7, on distribution of medical care.

DR. ALBERT FRITSCHKE, of New Ulm, Minn., has been appointed a member of the Minnesota State Board of Medical Examiners, succeeding Dr. George B. Weiser.

DR. EDWIN R. VANDERSLICE, member A.P.H.A., has been appointed to succeed Dr. S. Rowland Hill as Health Officer of Lansing, Mich., who held the position for 12 years.

DR. SAMUEL R. MCKELVEY, of Denver, member A.P.H.A., has been reelected as secretary of the Colorado State Board of Health. Dr. McKelvey will become executive officer of the division of public health created as a part of the Colorado executive department in a reorganization of the state government by the last legislature. The new division combines all the functions of the state board of health, the meat and slaughter plant inspectors, and the state chemist under Dr. McKelvey's supervision, subject to control by the state board of health.

CONFERENCES

July 29–August 4, World Federation of Education Associations, Dublin.

September, 1933, European Reunion on Mental Hygiene and Prevention, Rome, Italy.

September 5–7, Seventh Annual Conference of the Pennsylvania Sewage Works Association, State College, Pa.

September 27–28, Second European Reunion on Mental Hygiene, Rome.

October 7–9, Public Health Education Institute.

October 7–9, Conference of State Sanitary Engineers, Indianapolis, Ind.

October 9–12, Sixty-second Annual Meeting of the American Public Health Association, Indianapolis, Ind.

October 9–12, American Association of School Physicians, Indianapolis, Ind.

October 9–12, Conference of State Laboratory Directors, Indianapolis, Ind.

October 9–12, International Society of Medical Health Officers, Indianapolis, Ind.

October 9–12, Association of Women in Public Health, Indianapolis, Ind.

October 12, Central States Sewage Works Operators Association, Indianapolis, Ind.

October 12, Indiana State Nurses' Association, Indianapolis, Ind.

October 12, Indiana League of Nursing Education, Indianapolis, Ind.

October 12–14, American Social Hygiene Association, Indianapolis, Ind.

October 12–14, International Association of Dairy and Milk Inspectors, Indianapolis, Ind.

November, 7th American Scientific Congress, Mexico City.

February 5–9, 1934, Third International Heating and Ventilating Exposition, Grand Central Palace, New York, N. Y.

March 29, 30, 1934, Annual Meeting of the American Association of Pathologists and Bacteriologists, Toronto, Ont., Canada.

Spring, 1934, Statistical Conference, International Statistical Institute, London, England.

1935, International Congress on Mental Hygiene, Paris.

The Sanitary Control over the Production and Handling of Shellfish on the Pacific Coast*

CARL E. GREEN

Sanitary Engineer, State Department of Health, Portland, Ore.

WITH the appearance of numerous and widespread cases of typhoid fever in the eastern part of the United States in the latter part of 1924 and in the early part of 1925, studies were made by health authorities to determine the sources of the infection. After considerable study the investigators concluded that oysters were responsible. To protect the public health and to restore public confidence in the shellfish industry, a committee, known as the Committee on the Sanitary Control of the Shellfish Industry in the United States, was formed on February 19, 1925, to study the problem. Representatives of the shellfish industry as well as federal, state and municipal health officials were included in the personnel. A report by this committee was made to the Surgeon General of the U. S. Public Health Service in 1925, in which were recommended minimum requirements for control of the shellfish

industry. Two supplementary reports have since been issued. Speaking generally, it is these minimum requirements which are followed by the U. S. Public Health Service and the various state agencies engaged in the sanitary control of shellfish.

On the Pacific Coast Washington led the way in June, 1927, when the State Board of Health adopted rules and regulations for the sanitary control of shellfish. Oregon and California followed in January, 1932, and Washington amended its regulations in January, 1933. The requirements of the three Pacific Coast states are practically identical and in general conform with the minimum requirements of the U. S. Public Health Service.

Though the term shellfish as used in various state regulations includes all varieties of clams, mussels and scallops as well as oysters, this paper will be limited to a discussion of the sanitary control of oysters. From a public health point of view oysters are the most important of the shellfish group for the following reasons:

* Read before the Session on Sanitation, Water, Food and Milk of the Fourth Annual Meeting of the Western Branch of the American Public Health Association, Pasadena, Calif., May 30, 1933.

1. The location of oyster beds and the feeding habits of oysters make them generally more subject to pollution than other shellfish.
2. Methods of production, handling and distribution are such as to increase the likelihood of contamination.
3. Large numbers of oysters are eaten raw, whereas most other shellfish are thoroughly cooked before being eaten.

On the Pacific Coast three species of oysters are found: (1) *Ostrea lurida*, or Olympia, which is native to the Pacific Coast; (2) *Ostrea virginica*, or eastern, which has been transplanted from the Atlantic and Gulf states; and (3) *Ostrea gigas*, or Japanese, which has been imported from Japan and is known in the west as the Pacific oyster.

Oysters are an excellent food. They contain proteins, fats, carbohydrates, vitamins A, B, and C and many mineral constituents. Because of their high iron and copper content, they are especially valuable in the treatment and prevention of anemia. No other commonly used food except liver surpasses oysters in the amounts of iron and copper furnished in average servings. Other valuable elements are manganese, calcium and iodine. During the feeding season oysters store up large quantities of glycogen. Glycogen and the other constituents of oysters are easily digested even when eaten raw; consequently, they are an ideal food. It is unfortunate that such a valuable food should be open so easily to contamination either in the growing area or later as it is being handled and distributed. It is the duty of health officials to protect the public by requiring that all oysters be produced, processed, packed and distributed in accordance with approved sanitary methods. The safeguards in the oyster industry should be similar to and as effective as those placed around the production and handling of raw milk.

The state of Washington is by far the largest producer of oysters on the

Pacific Coast. This is due to the fact that there are many extensive areas in the state which are suitable for oyster culture. Suitable bays and inlets in Oregon and California have been developed, but the intensive cultural methods of the Washington growers have not yet been largely adopted by the other states. British Columbia produces Olympia oysters, particularly in Ladysmith Harbor and Boundary Bay, some of which are shipped into the United States.

The phenomenal growth of the Pacific Coast oyster industry during the past three years can be accounted for by the importation of seed oysters from Japan. The most extensive plantings have been made in Puget Sound, Gray's Harbor, and Willapa Bay, all of which are in Washington. Growers in all three coast states have transplanted eastern oysters into the numerous bays available, but except in a few instances the eastern oyster has failed to propagate in western waters. At present most eastern oysters sold on the Pacific slope are secured direct from the Atlantic seaboard.

Japanese oysters have failed successfully to propagate in waters of the Pacific Coast, but because seed oysters may be purchased from Japan so cheaply very little effort has been made to secure heavy sets of "spat." It is probable that the water of the west coast is not sufficiently warm to cause complete development of oyster larvae. Under favorable conditions, heavy sets of native oysters can be secured.

It is evident that the production of Japanese oysters on the Pacific Coast is rapidly increasing. In most bays intensive fishing of the natural oyster beds long ago depleted the native species. Artificial methods of growing now widely practised have resulted in high yields per acre. In this cultural method the Puget Sound oyster growers have led.

Japanese, or Pacific, oysters were first planted on the Pacific Coast in the waters of Puget Sound in 1902, but extensive plantings were not begun until 1928 and 1929. In each succeeding year increasing numbers of cases of seed have been planted. The hardness of the Pacific oyster, together with the rapidity with which it grows to a

ing opening and packing. It is of prime importance that all market shellfish be taken from clean areas. To determine whether or not a given area is safe, it is necessary to make a sanitary survey of the area and the surrounding country. Bacteriological examinations are made of the shellfish and of the water overlying the beds. The findings

* Data from reports of Washington State Dept. of Fisheries and U. S. Dept. of Commerce.

marketable size, has been largely responsible for the continued increase in importation. Instead of requiring from 3 to 5 years to attain marketable size, as required by the Olympia and eastern oysters, those imported require from 1½ to 3 years. This rapid growth can be accounted for by the fact that the Japanese oyster passes far greater volumes of water through its gills in a given length of time than the native or eastern species. Since oysters obtain their food by straining out from the water microscopic material such as diatoms, it follows that the more water pumped through the gills the more rapid the growth.

Oysters are more apt to become contaminated on growing areas than dur-

ing opening and packing. It is of prime importance that all market shellfish be taken from clean areas. To determine whether or not a given area is safe, it is necessary to make a sanitary survey of the area and the surrounding country. Bacteriological examinations are made of the shellfish and of the water overlying the beds. The findings

of sanitary surveys are essential in the interpretation of laboratory results and, conversely, laboratory analyses are often necessary to substantiate field data. Sanitary surveys are made to determine the extent of existing and potential sewage pollution both at the growing area and in the surrounding country. In no case can direct fecal pollution of water near growing areas be tolerated. If sewage is discharged into the water at a distant point, consideration is given to the extent of sewage treatment, if any, before discharge, the amount of dilution available, the extent of natural purification which may take place, the temperature of the receiving body of water, and the time of flow to the

oyster beds. The likelihood of pollution from boats must also be given study.

In Oregon water samples for bacterial examination have been collected on both ebb and flood tides. The number has varied with the area under consideration—generally from 12 to 30 samples are taken on a single tide, the points of collection being approximately equidistant over the area studied. After a sanitary survey has been made of the surrounding country, one can usually tell whether to expect the best bacteriological results on the ebb or flood tide. Once this has become known, it has been the practice to limit sample collection to the tide which is apt to give the most pollution. In the early part of the work bottom water samples were often collected, but in most bays there was little difference between the *B. coli* scores of surface and bottom samples. Practically all samples are now collected from 6 inches to 12 inches below the surface.

Occasionally shellfish samples are dredged or tonged from the beds and sent to the laboratory for examination. Most investigators have found a wide variation in the *B. coli* scores of shellfish liquor. These discrepancies, together with the fact that the laboratory examination of shellfish is more laborious and time consuming than that of water, have led most states to rely mainly upon *B. coli* scores of the overlying water. Wide variations in shellfish liquor scores may be due to the fact that we are working with a living organism.

On the Pacific Coast, *B. coli* scores of shellfish liquor averaging about 2 and rarely exceeding 5 have been considered satisfactory. No allowable *B. coli* score, either of shellfish or of water overlying growing areas has been set by the western states. In some eastern states water scores not exceeding 2.3 to 3.6 are specified. Others recommend

a maximum allowable score of 2.5, or not more than 50 per cent of the 1 c.c. portions positive for the coli-aerogenes group. In the west certainly the problem of sewage pollution is not so great as that in the oyster producing areas of the east, for the reason that the population on the Atlantic seaboard far exceeds that on our Pacific Coast.

The recommendations of the U. S. Public Health Service state that laboratory findings should be interpreted in view of the sanitary survey data. This should be done; nevertheless, there is need of a definite standard to be used throughout the country. At present each state seems to have its own standard, or frequently, no definite standard for approved areas.

In the bacteriological examination of shellfish liquor practically all the states follow the standard methods of the A.P.H.A. There is need for uniformity in the examination of water overlying shellfish areas. Routine procedure should include the examination of 5 portions each of 10 c.c., 1 c.c. and 0.1 c.c. of water, following the standard methods used in the bacterial analysis of water. A uniform standard for the quality of shellfish area water should be established, preferably by the U. S. Public Health Service. Standards for the certification of water supplies used on interstate carriers have been established, and there should be no legitimate objection to a reasonable standard for shellfish growing areas, the oysters from which are usually shipped interstate.

The regulations of the Pacific Coast states permit the transplanting of shellfish from unapproved areas to clean areas provided no shellfish are removed for market in less than thirty days. Transplanting must be approved by the state shellfish control authority and must take place when the oysters are feeding actively. Hibernating oysters do not cleanse themselves of pollution even when placed in clean water.

Whenever possible, toilet facilities at culling houses and living quarters are required to be located on land at a safe distance from the water. If it is not possible to provide for land disposal, chemical toilets are required.

TABLE II

CASES * OF JAPANESE SEED OYSTERS PLANTED
IN OREGON AND WASHINGTON, 1930-1933

| <i>Year</i> | <i>Number of Cases</i> |
|-------------|------------------------|
| 1930 | 12,430 |
| 1931 | 15,710 |
| 1932 | 36,600 |
| 1933 | 46,020 |

* Each case of seed contains from 12,000 to 16,000 young oysters.

It is difficult, if not impossible, to keep shucked oysters clean during the opening process unless the shell stock is reasonably free from mud. In many areas, particularly where oysters are grown on mud flats, growers have been required to install washing equipment. Pumps using sea water are in general use for washing shellfish at the live floats.

Shucking and packing plants are required to be similar in construction to modern milk plants. Those approved by the state health departments have floors and opening benches of concrete or other equally impervious material. Smooth surfaced, painted and easily cleaned walls and ceilings, as well as plenty of light and ventilation have been required in all modern plants. All equipment with which shucked oysters come in contact is of smooth, hard surface material, free from corrosion, and free from seams, cracks and grooves in which bacterial slime or food particles may collect. Approved plants also have adequate facilities for the cleaning and bactericidal treatment of all utensils, containers, etc., as well as an abundant supply of hot and cold water under pressure.

It is practically impossible to keep

shucked oysters free from shell particles and other foreign matter during the opening process. It is, therefore, necessary to wash the shucked stock before it is packed for market. This can best be done with clean cold water. Various methods are used, but in most plants blowers or sprays have been found most effective. Whatever method is used, the washing process should be completed in three minutes or less. Shucked shellfish will "soak up" much fresh water if washed for long periods or allowed to stand in water. Some plants have found a 2 per cent to 3 per cent salt solution helpful in cleansing the oyster meats of adhering slime and particles of dirt.

Pacific oysters vary in size to such an extent that they must be graded at packing plants. Small oysters have a higher market value than large. Sorting or grading is done on monel metal tables which drain into the washing sink. Monel metal has been more successful for equipment and utensils than any other because it does not corrode and is easily kept clean and bright.

Refrigerators are used at all plants to cool shucked shellfish immediately after the washing and packing process. A temperature above freezing but below 50° F. is maintained in all cooling units. No ice or ice water is permitted to come in direct contact with shucked shellfish.

In an industry where there are so many dangers of transmitting the germs of infectious diseases to the product, rigid standards of cleanliness of employees must be enforced. Health examinations are given to all plant employees, and especial effort is made to detect carriers of typhoid, para-typhoid or other communicable diseases. No person who is suffering from, or is a carrier of, contagious disease or who has infected wounds on his arms or hands is permitted to work. All employees must wear clean garments. In addition,

shuckers must wear rubber or oil skin aprons and those washing or packing shellfish must wear rubber gloves. Washing facilities with hot and cold water, soap and individual towels, as well as sanitary toilet facilities, are a necessary part of all plants. All employees are required to wash their hands after each visit to the toilet and

signs to this effect must be posted in conspicuous places.

Uniform requirements and constant supervision over shellfish growing areas and shucking plants on the Pacific Coast are necessary to protect the public health and, incidentally, to encourage and safeguard a rapidly developing industry.

International Congress on Working Mothers and Their Children

THE first international congress on working mothers and their children was held in Paris from June 7 to June 11, 1933, under the auspices of the Union Feminine Civique et Socials. The purpose of the congress was to call the world's attention to the evils of the employment of mothers outside the home and to discuss its causes and remedies. The congress was attended by delegates from more than 20 countries, among them the United States.

Reports were read on the condition of wage earning women in various countries. It was pointed out that in France 35 to 40 per cent of all married women were employed outside their homes, and in this way 700,000 homes were deprived of their mothers during work hours; in Germany the number was almost the same; in Brazil, of 150,000 women factory workers 50,000 were married and had children; in Poland the number of working women was larger than that of working men; in Austria the number of married working women had constantly increased. It has been found that a married woman's work outside the home necessitates expenses which amount on the average to 50 per

cent of her earnings. The delegates spoke against day nurseries for infants, day centers for older children, and other unsatisfactory but costly measures that should be replaced by allowances to mothers, coöperative societies, and mutual aid funds, and by other arrangements. All speakers urged legislative measures for safeguarding the family.

The resolutions passed asked among other things for the payment of a wage sufficient to meet the normal needs of a family with the mother staying at home. In the meantime the conditions of women in employment should be made as satisfactory as possible. Society must increase the number of agencies, particularly mutual aid agencies, aiming to aid the home and to give a certain amount of security to the family. It was stated that international, as well as national, legislation is needed for this purpose.

Finally, the congress urged the establishment in all countries of committees, such as are already in existence in some countries, for the carrying out of the resolutions.—*Journal des Débats*, June 5-15, 1933; *Le Temps*, June 7-12, 1933; and *Le Matin*, June 5-13, 1933.

Resident Mortality from Tuberculosis in Urban and Rural New York According to Age, Sex, Color, and General Nativity*

ELIZABETH PARKHURST

*Senior Statistician, Division of Vital Statistics, New York State
Department of Health, Albany, N. Y.*

OFFICIAL vital statistics do not always measure accurately the natality and mortality of communities, mainly because of the general practice of registering births and deaths in the place of their occurrence, which often is not the permanent residence of the mother or of the decedent. In 1926, therefore, the Division of Vital Statistics of the New York State Department of Health undertook the task of measuring in a logical and consistent manner the natality and mortality among the residents of the more important administrative units of the State. Birth rates and death rates corrected for change of residence are now published in the annual reports of the Division. Special attention has been given to the determination of resident mortality from tuberculosis because the segregation of many sufferers from this disease in hospitals and sanatoria distorts, often to a degree of uselessness, the recorded rates of mortality in many urban and rural areas.† Table I illustrates the weight of residence in areas even as large as the city of New York and the entire urban and rural sections of the rest of the State:

The purpose of this paper is to analyze the resident tuberculosis mortality in the State and its main subdivisions according to sex, age, color, and nativity. The period chosen is the triennium 1929-1931. The fact that the latest census data are for the mid-year 1930 makes, of course, for the greater accuracy of the computed rates.

The number of deaths from all forms of tuberculosis of residents of New York City which occurred anywhere in the State in the course of the three-year period was 16,703; the corresponding number of deaths for the rest of the State was 10,134, of which 6,943 were of residents of the urban territory, 3,191 of rural New York. The rates per 100,000 population according to sex and age were as shown in Table II.

The curves of mortality for males begin with a peak in the youngest age

* Urban includes cities and other incorporated places whose population was 2,500 or more. Rural includes the remainder of the Upstate area.

group, under 5 years, coming down to a minimum in the age group 10-14 years and rising to a maximum at 55-64 years in New York City with the next highest rate at 45-54 years; in the urban part of the rest of the State the maximum rate was that at 45-54, the rate at 55-64, however, being of practically the same magnitude. In rural New York the peak was in the oldest

TABLE II

RESIDENT DEATH RATES, PER 100,000 POPULATION, FROM ALL FORMS OF TUBERCULOSIS BY SEX AND AGE: NEW YORK CITY AND URBAN AND RURAL AREAS OF REST OF STATE, 1929-1931

| Age | Males | | | Females | | |
|-------------------|------------------|---------------|-------|------------------|---------------|-------|
| | New York City | Rest of State | | New York City | Rest of State | |
| | | Urban | Rural | | Urban | Rural |
| Total | 97.6 | 76.2 | 55.5 | 62.2 | 53.7 | 46.2 |
| Under 5 Years | 49.0 | 31.0 | 20.5 | 41.2 | 27.9 | 17.8 |
| 5-9 years | 10.6 | 10.8 | 5.6 | 8.0 | 9.5 | 4.5 |
| 10-14 years | 9.7 | 11.3 | 6.7 | 15.2 | 13.4 | 9.7 |
| 15-19 years | 45.1 | 36.2 | 24.1 | 76.9 | 65.1 | 43.9 |
| 20-24 years | 87.8 | 67.0 | 42.9 | 107.9 | 91.5 | 96.6 |
| 25-29 years | 101.2 | 80.8 | 70.1 | 93.5 | 89.8 | 82.8 |
| 30-34 years | 107.2 | 94.0 | 87.4 | 80.2 | 74.0 | 77.0 |
| 35-44 years | 132.9 | 107.6 | 90.6 | 57.2 | 56.7 | 51.8 |
| 45-54 years | 170.9 | 131.6 | 77.6 | 56.8 | 48.5 | 41.6 |
| 55-64 years | 198.6 | 131.4 | 75.8 | 65.4 | 54.8 | 47.1 |
| 65-74 years | 163.6 | 114.8 | 81.5 | 67.7 | 61.3 | 61.5 |
| 75 years and over | 115.5 | 75.7 | 92.5 | 70.0 | 53.6 | 68.9 |

age group, 75 years and over, with an almost equally high rate at 35-44 years. Among females, we also find a peak in the youngest age group, under 5 years, with the minimum in the next group, 5-9 years; the maximum rates, however, were in much younger age groups than among males, the mortality in all three sections of the State being relatively highest among young women 20-24 years.

The total death rate in New York City exceeded the corresponding rate in the rest of the urban territory of the State by 28 per cent among males and 16 per cent among females. Specific death rates by age were, with the exception of the age groups 5-9 years and 10-14 years, higher in New York City, the excess ranging from 14 per cent in the group 30-34 to 58 per cent among children under 5 years. Since the last group is numerically small, it is important to note the excess in New York City mortality in the large group 55-64 years where it equalled 51 per cent. Among children 5-9 years of

age the rates were virtually equal, while in the next group, 10-14 years, the New York City rate was 14 per cent lower.

The death rates among females were higher in New York City at all ages, with the exception of 5-9 years. The excess of the New York City mortality, however, was not so great as among males, ranging from 1 per cent between 35 and 45 years to 48 per cent in the numerically small group under 5 years. Among children between 5 and 10 years, the New York City mortality was 16 per cent below the upstate urban rate.

Similarly, the urban upstate rate exceeded the rural rate at almost all ages, the exceptions being the groups 75 years and over among both sexes and 20-24, 30-34, and 65-74 years among females. The excess of the urban mortality upstate among males ranged from 8 per cent in the group 30-34 years to 93 per cent among children 5-9 years; next in size was the disparity in the age group 55-64 years—73 per cent.

* The numbers in these columns were not considered in the computation of the rates. It is clear, however, that their distribution upon any basis would not change the relationship between the rates of the several nativity groups.

Among females, the excess of urban mortality was greatest under 20 years, the disparity being as high as 111 per cent at 5-9 years. After age 20 the maximum difference was only 17 per cent, in the age group 45-54.

The striking fact that the major portion of the excess mortality in New York City and in the urban part of the rest of State as compared with rural New York was among males between the ages of 45 and 65 is clearly seen in Graph 1.

Another interesting form of comparison is that of the male and the female mortality. The total death rate among males exceeded the rate among females by 57 per cent in New York City, 42 per cent in the urban part of the rest of State, and 20 per cent in rural New York. The most significant fact is the excess of female mortality in the three sections of the State between 10 and 25 years of age. In addition, upstate, the mortality among females was higher than among males also in the age group 25-29 years. At all of the other ages in New York City the death rate among males was higher, the disparity being greatest, over 200 per cent, between 45 and 65 years. In the urban part of the rest of the State and in rural New York the mortality among males was relatively highest at 45-54, exceeding the female mortality by 171 and 87 per cent, respectively.

The analysis of resident tuberculosis mortality by color and general nativity had to be limited to the upstate area only, the necessary data for New York City not being available. Table III shows the specific death rates in the State, exclusive of New York City, according to sex, age, color, and the general nativity of the white population.

The death rate among negro males, 283.0, was more than four times the corresponding rate among whites, 64.9; the rate among negro females, 236.4,

was almost five times that among whites, 47.9. Without exception, the specific death rates by age were much higher than among whites. While the numbers upon which the negro rates are based are relatively small, deaths of negro males numbering 361 and females, 302, as compared with 5,438 and 3,985 for whites, the differences between the rates are of such magnitude that they are undoubtedly significant.

Among the three general nativity groups of the white population, the total death rate was lowest for the native-born of native parentage followed by the first native-born generation, the rate for the foreign-born being highest. When, however, we consider the mortality by age, we find that practically all the specific rates were higher among the first native-born generation than among the foreign-born. The differences between the rates for native-born persons of native parentage and those for persons of foreign birth or of immediate foreign origin were especially marked among adult males (see Graph 2). When the rates for the three groups are corrected for differences in the age distribution (by adjusting them to the population of the state, exclusive of New York City, according to age and sex), they are found to be as follows:

| | <i>Males</i> | <i>Females</i> |
|---|--------------|----------------|
| Native-born of native parentage | 45.0 | 39.3 |
| Native-born of foreign or mixed parentage | 82.3 | 56.5 |
| Foreign-born | 80.9 | 50.9 |

When the analysis is extended to the leading racial strains it is advisable to group the entire area of eastern and central Europe into a single unit because, in many instances, the information given on death certificates regarding country of birth does not correspond to the post-war boundaries. In no other way could one explain a tuberculosis rate of 279.8 for natives of Austria when the natives of Czecho-

GRAPH II

Resident Death Rates per 100,000 Population from All Forms of Tuberculosis by Sex, Age, and General Nativity of White Persons, in New York State, exclusive of New York City, 1929-1931.

slovakia show a rate of only 47.9; or a rate for natives of Hungary of 133.4, while the natives of Yugoslavia show a rate of less than half, 59.7. Although there were also modifications in the territories of Denmark and Italy, they were not sufficiently large to influence the validity of the rates.

The necessary population data not being available, it is impossible to make correction for differences in the age distribution of the foreign-born and the first native-born generation. No deductions, therefore, may be drawn from the comparative size of the total rates. It is interesting to note, however, that notwithstanding the undoubtedly more favorable age composition of the first native-born generation, the total death rate for persons of Irish parentage was higher than the corresponding rate for the natives of Ireland. Among the foreign-born, the Irish had the highest rate followed by natives of eastern and central Europe, while the Canadians and Italians showed the

lowest rates. In the group of native-born of foreign or mixed parentage, persons of Irish stock had the maximum

TABLE IV

RESIDENT DEATH RATES, PER 100,000 POPULATION FROM ALL FORMS OF TUBERCULOSIS: NEW YORK STATE, EXCLUSIVE OF NEW YORK CITY, 1929-1931

| Country of Birth or Origin | Foreign-born | Native-born of Foreign or Mixed Parentage* |
|-----------------------------|--------------|--|
| Total | 82.0 | 63.3 |
| Canada | 57.0 | 55.3 |
| England, Scotland, Wales | 62.0 | 58.5 |
| Ireland | 108.8 | 114.0 |
| Norway, Sweden, Denmark | 82.8 | 64.1 |
| Italy | 57.5 | 36.6 |
| Eastern and central Europe† | 100.2 | 59.3 |
| Other foreign countries | 106.0 | 54.7 |

* By country of birth of father, or if father was native-born or of unknown nativity, by country of birth of mother.

† Austria, Czechoslovakia, Germany, Hungary, Lithuania, Poland, Roumania, Russia, Yugoslavia.

rate and the Italian group the minimum.

Table V shows the death rates by age, sex, color, and general nativity in the urban and rural areas. The death rate of negro males was 345.3 in the urban area as compared with 117.6 in the rural area, and of negro females 280.1 in the urban area as compared with 106.0 in the rural. The total urban rate for males was 37 per cent higher than the corresponding rural rate and for females 11 per cent higher; if the death rates of whites only are considered, these differences are cut to 31 and 10 per cent, respectively.

The relationship mentioned earlier between the age and sex specific death rates for the three general nativity groups in upstate New York is found to exist when the urban and rural parts of the State are considered separately. Among males, the urban rates were higher than the rural except at 25-34 years for the two classes of native-born and at 35-44 years and the numerically unimportant group "under 15 years" for the foreign-born. The disparity between the rates was greatest between 45 and 65 years: 42.5 per cent for the native-born of native parentage, 73.3 per cent for the first native-born generation, and 56.0 per cent for the foreign-born. Among females, the differences in the urban and rural rates were negligible, the rural rates slightly exceeding those in the urban area between 25 and 45 years for the native-born of native parentage, between 15 and 45 and after 65 years for the first native-born generation, and between 25 and 45 for the foreign-born.

If the distribution of the rural population according to age, sex, color, and general nativity were the same as in the urban upstate area the total rural rate would be increased from 51.0 to 55.3. This corrected rate is still 15 per cent lower than the urban rate, 64.8.

General Summary—In 1929-1931, the excess of the resident tuberculosis

mortality in New York City and in the urban part of the rest of the State, as compared with that of rural New York, was almost wholly due to the higher death rates among adult males, particularly between the ages of 45 and 65 years.

The death rates among males exceeded the rates among females at practically all ages with the important exception of the age groups 10 to 25 years in New York City and 10 to 30 years in the rest of State, where the mortality among females was *higher* than among males. The excess of male mortality was greatest in New York City, amounting to as much as 200 per cent between the ages of 45 and 65. In the urban and rural parts of the rest of State the difference was greatest in the age group 45 to 54 years—171 per cent in the urban and 87 per cent in the rural area.

The death rate among negroes greatly exceeded that among whites. The difference was especially marked in the urban area, where the negro male rate was 4.8 times and the female rate 5.2 times the white rate. In the rural area the negro rates for both males and females were slightly more than twice the corresponding rates among whites.

In the three general nativity groups of the white population, the total death rate was lowest among the native-born of native parentage, followed by the native-born of foreign or mixed parentage—the rate among the foreign-born being highest. When age specific death rates are considered, however, the rates at practically all ages are found to be *higher* among the first native-born generation as compared with the foreign-born. The differences were greater among males than among females and greatest among males between the ages of 45 and 65 years.

Among persons of foreign birth or immediate foreign origin, the crude death rates were highest among the

* See footnote to Table III.

Irish and lowest among the Italians. In spite of the more favorable age distribution of the population, the death rate of native-born persons of Irish parentage was higher than that of natives of Ireland.

When correction is made for differences in the distribution of the population by age, sex, color, and general nativity, the total rural resident rate is found to be 15 per cent below the urban rate.

CONCLUSION

The causative factors in the higher urban mortality from tuberculosis are very likely environmental, since the excess over rural mortality remains when correction is made for the unlike sex, age, color, and nativity composition of the population. In view of the fact that the disparity is greatest among males between the ages of 45 and 65, it seems reasonable to assume that occupation is an element of prime importance.

Relative Merits of Raw and Pasteurized Milks

. . . There are, therefore, strong grounds for the belief that infants can satisfy all their requirements on diets of adequate amounts of pasteurized milk provided that extra vitamin D, and, of course, vitamin C, are added to the diet.

The subject is, however, one which demands further investigation. No body of evidence is available on which a really conclusive statement of the relative merits of raw and pasteurized milk, when fed without vitamin supplements, can be founded. This is surprising in view of the facilities afforded by child clinics for a really informative study of the question. Moreover, our whole knowledge of the metabolism of infants is singularly meager, and it is highly desirable that further work should be done in this field. More especially is it desirable, in view of the

importance of calcium and phosphorus in the building up of the skeleton, that the requirements of children for these elements at various stages in the life-history should be more firmly established. Investigation should also be made into the quantity of milk which is necessary for the optimum retention of calcium and phosphorus, while the effect of variations in the vitamin D intake should also be studied. In this way there could be built up a body of knowledge which would not only be of great value in determining the relative merits of raw and pasteurized milk in infant feeding, but which would furnish a useful guide to pediatricians in the more general field of infant dietetics. —J. S. Stirling and J. H. Blackwood. *The Nutritive Properties of Milk in Relation to Pasteurisation*. Hannah Dairy Research Institute. *Bull.* 5, p. 75.

The Treatment of Water by Certain Forms of Silver

JAMES GIBBARD, F.A.P.H.A.

Bacteriologist, Laboratory of Hygiene, Department of Pensions and National Health, Ottawa, Ont.

IN Canada and the United States one seldom hears of any process other than filtration and chlorination recommended for the treatment of polluted water supplies. Recently a new method involving the use of silver, has been receiving considerable attention, especially in Europe. The apparatus designed to apply this new process is now sold in Canada and presumably in the United States, and it is believed that patent rights for this new method have been issued.

This process depends upon the so-called oligodynamic action of silver. It is a well-known fact, first reported by Naegeli in 1893, that silver metal exerts an inhibitive action toward bacteria, algae and certain other forms of microscopic life. The term "oligodynamie," coined by Naegeli, is used to define that bactericidal action of silver, copper, mercury, etc., and their salts, which occurs in such a dilute concentration that a chemical determination is extremely difficult. In fact for many years the inhibitory action of the metals was thought to be mysterious, but it is now generally accepted that the metals act only through the solution of traces of salts or oxides on their surface. When water is exposed to metallic silver it develops oligodynamic properties reaching a maximum in about eight days, but if the area of metal exposed to water is increased many hundreds of times the time factor is greatly reduced.

In this new process silver with or without certain "activators" such as palladium or gold, is deposited on the surface of sand, porcelain, or filter candles. Water is then passed through the filter or allowed to remain in contact with the silvered porcelain for a certain time. Very striking claims are made for this method:

- (1) There is no taste, odor or color to water treated by this method.
- (2) Water which has been exposed to silver has the power of sterilizing other polluted water mixed with it.
- (3) It is claimed to sterilize polluted water independent of the temperature of exposure.
- (4) There is no reduction in the efficiency of this new process by the presence of minerals or organic matter in the water.
- (5) The quality of the water is only of importance when it contains much suspended matter.
- (6) It is recommended for the treatment of water in swimming pools, laundries, drains, ice plants, etc.
- (7) Certain claims for medicinal application are made.

It will be seen that *if* this process is all that is claimed for it, we have available the ideal method of treating polluted water.

It is well at this stage to point out that although this process has important limitations, it has some points in its favor, and, in the author's estimation, is worthy of considerable further research.

As regards "oligodynamie" in gen-

eral, there have been at least 200 publications dealing with various phases of the problem.

Suckling^{1, 2} studied this method of treating water and concluded that "it is a delicate process susceptible to interference by many factors such as temperature, turbidity, sulphides, chlorides, iron and organic matter. As far as public water supplies are concerned, the process is applicable to few and carefully selected cases. It is superior to chlorination in certain minor respects such as the entire absence of odor and taste production." He believes that it "may meet a long-felt need as a means of sterilizing water in the case of small supplies, country homes, etc."

It seemed desirable to obtain some first-hand data regarding this new process, while for comparison, studies on silver-plated porcelain, colloidal silver and silver nitrate were included.

One specimen of the commercial apparatus was obtained. The sterilizing elements consisted of small unglazed porcelain rings, each approximately 1.5 cm. in diameter, 1.5 cm. deep, the walls 0.2 cm. thick. These rings had silver in some form, presumably metallic, on the surface. Upon breaking a ring and heating it with H_2S , marked discoloration occurred at the surface only and it is therefore concluded that silver was deposited only on the surface. A quantitative determination of silver on 1 ring indicated 7.5 mg. There is undoubtedly considerable variation, as microscopic and macroscopic examination showed a considerable unevenness in deposit. The apparatus, which was designed to treat, by contact, 1,300 c.c. of water, contained approximately 400 rings. The directions were simply to rinse the jar, fill with water, allow to stand two hours, when the water would be found to be sterile unless it had approached sewage in its degree of contamination, in which case 6 to 7 hours would be necessary.

Preliminary experiments were done with the sterilizer as sold by the manufacturers. The jar was filled with tap water to which enough of broth culture of *B. coli* or *B. typhosus* was added to give approximately 1 million viable organisms per c.c. The test was conducted at 22° C. At half-hour intervals 5 c.c. of water were removed from the jar and inoculated into Smith fermentation tubes of lactose broth. Growth occurred from samples removed after one hour, but all cultures were negative after two hours' exposure. Those tubes which showed no growth were then reinoculated with the test organism, in order to determine whether or not enough of the inhibitive material might be carried over to prevent growth. In every case excellent growth took place. It was concluded that the process warranted further study.

It was considered advisable to remove the silvered rings from the apparatus for experimental purposes, and place them in 400 c.c. pyrex beakers for further study, in order that they would not all be affected by some special experiment. In addition broken porcelain insulators and later porcelain rings, plated with silver by one of the usual chemical reduction methods, were used in identical experiments.

Distilled water suspensions of 24 hour broth cultures of *B. coli* were used. Five c.c. amounts of the suspension were removed at half-hour intervals and inoculated into lactose broth Smith fermentation tubes. In this report "sterility" means that growth did not occur when the sample was inoculated into lactose broth and incubated at 37° C. for 48 hours.

At room temperature (22° C.) water with approximately 2 million *B. coli* per c.c., was sterilized by silvered commercial rings in slightly less than four hours; at 37° C. in two hours, while at 10° C. not even after 22 hours. Identical results were obtained with the

silvered rings prepared in the laboratory.

A variety of experiments was conducted, during which it seemed as if both the commercial and the laboratory rings were losing their efficiency, so a comparison was made with new rings. Sterility was obtained at room temperature within four hours with the used rings, but in two hours with the new ones.

These results were repeated several times and indicated that under continued use there is a gradual loss of efficiency of both commercial and laboratory rings. It was believed that the use of broth cultures in preparing the suspensions of *B. coli* for test purposes might be a factor through the addition of organic matter. Only 1 to 2 c.c.'s of a broth culture were used to prepare a litre of suspension, and this quantity of broth would represent very little organic matter. In order to avoid objections on this point, all further suspensions were, unless otherwise stated,

prepared from *B. coli* grown on an agar slant and filtered through paper. Even under these conditions there is a gradual loss of efficiency of the rings.

It was also found that when the bacterial content was greatly increased, there was a corresponding increase in the time necessary for sterilization. Water with 500,000 *B. coli* might be sterilized at room temperature within 1½ hours, but with 10,000,000 per c.c. may take ten hours. Although it is possible that the same rate of action on *B. coli* took place in both samples, the result was a greatly increased time.

Temperature plays an important rôle in sterilization. Distilled water containing a suspension of *B. coli* may be sterilized in from 1½ to 2 hours at 22° C., while at 8° it may require six or seven hours, indicating that even with the most favorable type of water the temperature is a very important factor.

Sixteen experiments were conducted to determine rates of reduction in the

FIGURE 1.
RATE OF REDUCTION IN NUMBERS OF VIABLE *B. coli*
EXPOSED TO SILVERED RINGS

number of *B. coli* suspended in distilled water when exposed to silvered rings at room and refrigeration temperatures. Control experiments were conducted on *B. coli* suspended in distilled water and 1 per cent sodium chloride. The cultures for these control tests were grown on either sodium chloride free agar or 1 per cent sodium chloride agar. A semi-logarithmic graph (Figure 1) shows these results to the best advantage.

Table I shows the silver content of water exposed to silvered laboratory and commercial rings. The spectrograph was employed.

TABLE I

SPECTROGRAPHIC QUANTITATIVE DETERMINATIONS OF SILVER IN WATER *

| <i>Water exposed to silvered commercial rings</i> | <i>Silver in parts per million</i> |
|--|--|
| After 1 hr. exposure | 0.03 p.p.m. |
| After 2 hrs. exposure | 0.07 p.p.m. |
| After 4 hrs. exposure | 0.15 p.p.m. |
| After 8 hrs. exposure | 0.5 p.p.m. |
| <i>Water exposed to silver plated laboratory rings</i> | |
| After 1 hr. exposure | 0.125 p.p.m. |
| After 4 hrs. exposure | 0.2 p.p.m. |

* Acknowledgment is gratefully expressed to Mr. J. Dick for conducting these analyses.

It will be seen that the quantity of silver in the water increases with the length of exposure.

Silvered commercial and laboratory rings which have become inactivated can be revived by treating with 10 per cent HCl for one hour and then thoroughly washing. It is difficult to determine whether or not this so-called oligodynamic effect is metallic in nature or due to traces of soluble salts or oxides on the surface. Hydrogen ion concentration was not a factor after this treatment.

The effect of light on silver plated

laboratory rings was studied at room temperature. Two dishes with 1 layer of rings were prepared. One was kept in a dark room and 1 in daylight, but away from direct sunlight. The temperature, bacterial count, condition of rings and method of sampling were as nearly identical as possible. It was found that the rings were not as active in the light as in the dark. The difference in time necessary to sterilize a *B. coli* suspension varied considerably, and was found to be as much as one hour longer for those rings kept in the light. Unfortunately, rate curves were not prepared. It was quite evident that there is some photo-effect which needs further study.

When comparisons were made between sterile raw water and sterile distilled water to which was added a filtered 24 hour culture of *B. coli* to approximate 1 million per c.c., the organisms suspended in distilled water were killed or rendered inactive more quickly by silver plated rings than those in raw water. This indicates that the nature of the water treated markedly affects the results. That this difference was not due to distilled water against raw water is shown by the normal death rate of *B. coli* suspended in distilled water (Figure 1).

Several experiments were conducted in an attempt to determine whether or not the organisms are actually killed by exposure to silver. Thus far it has not been possible to obtain any definite evidence of revival, although doubtful results were obtained in one test. Further work is indicated in light of the reported revival of organisms exposed to copper.

Sterile distilled water was exposed to silvered laboratory porcelain rings for several hours, removed and its action against *B. coli* determined. It was found that it had acquired considerable sterilizing effect, as would be expected from the spectrographic determination

of the silver content of exposed water (*vide supra*).

SILVER NITRATE

The action of silver nitrate was also studied. The dilutions are expressed on the basis of the silver ion-content.

It was found that in a dilution of 1 in a million silver nitrate sterilized water containing a million and a quarter *B. coli* per c.c. in less than $\frac{1}{2}$ hour, while a 1 in 10 million required $1\frac{1}{2}$ to 2 hours at 22° C. and $2\frac{1}{2}$ to 3 hours at 8° C. The effect of temperature on the action of silver nitrate on *B. coli* is not as great as in the case of either the silvered rings or colloidal silver. It was noted, strangely enough, that 0.1 per cent normal horse serum seemed to increase the rate of action.

The effect of light was also studied but no difference could be noted between experiments conducted in the dark and those conducted in the light.

Another series of interesting experiments was conducted with silver nitrate. Tubes of lactose broth were prepared with a 1 in 100,000 concentration of silver nitrate. A definite number of organisms was added to each tube and incubated at 37° C. No growth was obtained in any tube inoculated with less than 200,000 *B. coli*, while all inoculated with 200,000 or more grew. A concentration of 1:10,000 AgNO_3 prevents growth in a tube inoculated with 100 million *B. coli*. A set of tubes was prepared with 1:100,000 silver nitrate and allowed to stand at incubator temperature for 48 hours and at room temperature for ten days. They were then inoculated with varying numbers of *B. coli*. A control set without silver nitrate was inoculated with a similar number of *B. coli*. All of the control tubes showed growth within 24 hours. Those which had silver nitrate added, and were inoculated with 200 or more showed excellent growth, but growth was prevented when only 20 *B.*

coli were used. The difference noted between this experiment and the first one described suggests that the combination of AgNO_3 with something in this broth results in inactivation.

COLLOIDAL SILVER

The action of silver sols on bacteria has been studied by Marshall.³ He reported that silver nitrate was more active than silver sols, *i.e.*, that silver nitrate calculated as 1 part of silver in 3,200,000 killed *B. typhosus* in 10 minutes, whereas a silver sol containing 1 part silver in 25,000 failed to kill in 15 minutes, but killed in 30 minutes. Marshall used Bredig's method, which produces particles of various sizes, most of which are so large that they readily precipitate. In this research a new electric dispersion method described by Fraser and Gibbard⁴ was used, by which a clear, yellow, silver sol was prepared. It was found that the concentration of silver in an effective silver sol was of the same order as the concentration of silver as silver nitrate, producing similar results. In addition, the concentration of silver in water exposed to silvered commercial rings or silver plated rings was also of the same order. A concentration of silver (colloidal silver) of one in 10 million in distilled water produces sterility in $3\frac{1}{2}$ hours at 23° C., and in 6 hours at 8° C. It was found that the action of colloidal silver on *B. coli* is affected by the presence of organic matter and temperature of exposure.

It is believed, therefore, that colloidal silver has an inhibitory or oligodynamic action similar to that of silvered commercial rings, or silver plated porcelain.

SILVER CHLORIDE AND FUSED SILVER CHLORIDE (HORN SILVER)

The effect of silver chloride was studied in a few experiments, with results similar to those obtained with

silver nitrate. A concentration of 1 part of AgCl in a million parts of distilled water sterilized a million *B. coli* per c.c. in 2½ hours.

Horn silver, or fused silver chloride, had a more rapid action, producing sterility in ½ to ¾ of an hour. However, quantitative determinations of the solubility of fused silver chloride were not made; consequently the results are not quite comparable.

METALLIC SILVER

The action of metallic silver in agar plates heavily seeded with *B. coli* was studied.

Pure sheet silver was obtained (99.98 per cent pure); a small strip as first obtained was placed in an agar plate. A zone of inhibition ¼ inch wide surrounded the silver after 24 hours' incubation. Another experiment was set up in which strips ¼ inch wide and 1 inch long were used. One strip was cleaned by fine emery paper, another was heated to a red heat in a bunsen flame and a third was held above the tip of the flame for about one minute. Neither the cleaned silver nor that heated to redness gave any zone of inhibition, while one held over the flame gave a zone of inhibition at least ¼ inch wide. The inference is, of course, that the inhibitory or oligodynamic action on *B. coli* is due entirely to traces of salts, oxides or sulphides on the surface.

After some days a plate which had shown a zone of inhibition was seen to have colonies growing in the clear zone. It is suggested that there is a distinct possibility of developing silver-resistant strains of *B. coli*. This point has not been studied, but will be kept in mind in future work.

MISCELLANEOUS EXPERIMENTS

One. A number of flasks and beakers, some of which were etched with hydrofluoric acid, were plated with

silver by the same chemical reduction process used for plating the porcelain. It was found that quite good oligodynamic action was secured. The rate of action was definitely co-related with the ratio between the capacity of the beaker and its wall area. The narrower the ratio between surface and volume the more quickly were the organisms affected. The suspension contained 700,000 *B. coli* per c.c. The experiment was conducted at room temperature. The main objection to this process from a practical point of view is that the silver plating on polished or etched glass did not adhere under the usual washing and cleansing conditions with soap and water.

Two. Double distilled water exposed to silver plated laboratory rings forty hours was boiled down from 500 c.c. to 10 c.c. and immediately diluted to 500 c.c. A suspension of *B. coli* was added to give a count of approximately 2 million per c.c. In addition, two control experiments were conducted with water exposed to silver which had not been boiled. The test was conducted at 22° C. It was found that while *B. coli* failed to grow after six hours' exposure to the control "silver" water, excellent growth was obtained after 24 hours' exposure to the boiled "silver" water.

SUMMARY

1. Distilled water suspensions of *B. coli* are apparently killed by exposure to silvered porcelain rings, without affecting color, odor or taste of the water.

2. There is a very definite time factor for silvered commercial rings and silvered laboratory rings to affect *B. coli* even under optimum conditions.

3. Although definite evidence of revival of organisms exposed to silver has not been obtained, further investigation is necessary before any final conclusion can be made.

4. The quantity of silver in water ex-

posed to silvered commercial rings, or to silver plated laboratory rings increases with the time of exposure, introducing another variable factor.

5. The presence of organic matter markedly increases the time of exposure necessary to prevent subsequent growth of *B. coli*.

6. The temperature of exposure markedly affects the rate of action of silvered rings, the sterilizing time increasing with lowered temperatures.

7. Rings which become inactive may be reactivated by treating with dilute HCl.

8. Silvered laboratory rings are more active in the dark than in the light.

9. Water which contains silver after exposure to silver plated porcelain has, as would be expected, the ability to inactivate *B. coli* added to it.

10. The effect of light on the action of silver nitrate on *B. coli* was studied, but it was found that under the most carefully controlled conditions there was no difference.

11. The concentration of silver in water exposed to silvered rings which is effective against *B. coli* is of a similar order as the effective concentration of silver in a silver nitrate or silver chloride solution and colloidal silver.

12. In general those factors which

affect the so-called oligodynamic effect of silver metal also affect the action of the other forms of silver studied.

CONCLUSIONS

It may be concluded, as a result of these laboratory studies, that although the application of the oligodynamic action of metallic silver to the treatment of water has some points of considerable interest, it cannot at the present time be recommended for practical use. Temperature, organic and inorganic constituents definitely influence the "oligodynamic" action of silver toward *B. coli* to a degree which renders the results unsatisfactory for practical application.

Furthermore, the definite, rather prolonged time factor which markedly increases under unfavorable conditions, necessitates constant and careful bacteriological control. The lack of a simple, delicate test for silver would require water to be stored until a bacteriological analysis could be completed.

A Study of the Opsono-Cytophagic Power of the Blood and Allergic Skin Reaction in Brucella Infection and Immunity in Man*

I. FOREST HUDDLESON, HOWARD W. JOHNSON
AND E. E. HAMANN

*Central Brucella Station, Bacteriological Section, Michigan State
Experiment Station, East Lansing, Mich.*

IN a series of studies which the writers have been conducting for the past two years, in connection with the phenomenon of phagocytosis and allergic reactions in Brucella infection in man and animals, evidence has been obtained to the effect that one of the most important indications of infection with, and immunity to, Brucella in man is the phagocytic response of the blood, based on measurements made *in vitro* in an opsono-cytophagic system and the existence of a state of allergy as determined by an allergic skin test.

Since the widespread occurrence of undulant fever in man in the United States was established, considerable attention has been given to the diagnosis of the disease, chiefly by cultural, serological and allergic methods. There are being accumulated data which indicate that the methods of diagnosis just mentioned are not always satisfactory in detecting many cases of the disease in man. Again, there are times when the results of the serological or allergic tests are misleading which in turn may result in an incorrect diagnosis.

Many physicians often observe the occurrence of a symptom-complex in patients not unlike that of acute or chronic undulant fever. One may be confused in making a diagnosis because, if Brucella infection is suspected, it might easily be ruled out on the basis of a negative blood, stool and urine culture, and negative agglutination test. If in addition to these examinations an intradermal test is performed with a suitable agent and a positive reaction is obtained, this evidence alone is not sufficient to warrant a diagnosis of undulant fever. The diagnosis remains uncertain because all individuals who have been infected with Brucella as well as those who are actively infected will show an allergic skin reaction to a satisfactory Brucella allergin.

Confusion may again arise when individuals who are ill or who are apparently healthy are found to have Brucella agglutinins in their blood serum. Those comprising this group are chiefly laboratory workers, practising veterinarians, farmers and packing house employees. By way of illustration let us consider the status of practising veterinarians toward the disease. Those who are engaged in cattle practice come in contact with *Br.*

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27, 1932.

abortus to a greater extent than any other single group of people. It has already been shown by serological and intradermal tests made on veterinarians in Europe and this country, that a considerable percentage have *Brucella* agglutinins in varying degrees in their blood and give a positive intradermal test. While very few of them give a history of having a clinical course of the disease, many report the occurrence of skin eruptions and malaise after removing retained placentas from aborting cows. The malaise is usually characterized by dullness, head-ache, sweating, aching in the muscles and joints. There may occur an elevation of the temperature. These symptoms may also occur from the ingestion or inhalation of the organism alive or dead, or of sterile broth filtrates on which the organism has grown. It is necessary, of course, that these materials pass through the epithelium of the skin, or the respiratory or digestive tract. Individuals in the general population as well as those in particular groups may show the symptoms just mentioned when exposed to *Brucella*.

We have conclusive evidence that all of those individuals who recover from *Brucella* infection, be it clinical or sub-clinical, are left sensitive and in some cases hypersensitive to *Brucella*, perhaps for several years. Such individuals show not only a local reaction to the intradermal test when made, but may show symptoms exactly like those seen in typical undulant fever as well. The differentiation of such cases from active infection with *Brucella*, or from many other diseases characterized by similar symptoms, has been a difficult problem to the clinician.

In attempting to arrive at a satisfactory method of detecting *Brucella* infection in those who do not show agglutinins in their blood and of clarifying the status of those individuals who show symptoms characteristic of

the disease when exposed to *Brucella* or to protein fractions of the organism, it was thought that a study of the phagocytic power of the blood in conjunction with an allergic skin test might possibly furnish considerable information on these problems and clarify the diagnosis of *Brucella* infection in many cases.

The literature is rather extensive on the phenomenon of phagocytosis and its meaning with respect to infection and immunity in other bacterial diseases. The application of allergic skin tests in detecting *Brucella* infection has also been given considerable study by many workers. Space does not permit at this time a review of the literature on all the important accomplishments in these directions.

Definite evidence was obtained during the course of these studies to support the view held by many others that a more accurate determination of an individual's actual phagocytic response to bacterial invasion may be gained by the use of whole blood, rather than by using the serum plus washed leucocytes of another individual or species of animal. In view of this fact the whole blood method was adopted for determining phagocytic response in *Brucella* infection and immunity in man in preference to the commonly used Wright and Douglas¹ opsonic index method.

Shortly after beginning this study we were surprised to find that the polymorphonuclear cells in whole defibrinated blood of many adults, regardless of their history as respects *Brucella* infection, show a decidedly marked ingestion of any of the three species of *Brucella in vitro* in a phagocytic system. Later it was found that when a certain amount of sodium citrate is added to a given specimen of whole blood, phagocytosis of *Brucella* is either inhibited, retarded or unaffected. The degree of phagocytosis that obtains

depends upon the history of the individual as respects *Brucella* infection. Hektoen and Ruediger² many years ago found that a great many other salts as well as sodium citrate, when added to whole blood in low concentrations, will retard or inhibit phagocytosis of certain bacteria. They succeeded in showing that the salts affected the opsonic property of the serum rather than the activity of the leucocytes.

We have found that the concentration of sodium citrate that is necessary to inhibit phagocytosis in whole blood varies with different species of animals. That is, a certain concentration of sodium citrate in the blood from one species of animal may prevent phagocytosis of *Brucella* altogether, but may not have the same degree of inhibiting action when added to the blood of another species of animal. By taking advantage of the inhibiting action of sodium citrate on phagocytosis, and applying it to a study of the opsono-cytophagic power of the blood of humans as respects *Brucella*, we find a marked difference in the opsono-cytophagic activity of the blood from the susceptible, from the infected and from the immune. In other words, one can measure an individual's status with respect to *Brucella* infection by determining the opsono-cytophagic power of the whole citrated blood *in vitro* for *Brucella*.

The concentration of sodium citrate in whole blood which has thus far given the most favorable results in determining gradations or degrees of phagocytic response toward *Brucella* sufficient for differentiating between the susceptible, the infected, and the immune is 0.8 per cent. If the concentration of sodium citrate in the blood is varied from the stated amount, differentiation between the three groups is not obtained.

In determining the phagocytic activity of whole blood, Glynn and Cox³ coined

the word "opsono-cytophagic" to indicate the phagocytic activity of blood in the presence of serum opsonins and homologous leucocytes. This expression has been adopted to describe the phenomenon with which this study deals. A description of the technic that has been employed and the results of the study follow.

METHODS OF STUDY

Determination of Opsono-Cytophagic Power of Blood. The method which we have adopted for determining the opsono-cytophagic power of blood for *Brucella* is a modification of the Leishman⁴-Veitch⁵ technic. The modified technic consists of mixing equal quantities of a citrated (0.8 per cent) fresh blood and a heavy bacterial suspension of living organisms in small Wassermann tubes, incubating at 37° C. for 30 minutes, and subsequently making spreads and staining with Hastings stain. The addition of a definite amount of sodium citrate prevents clotting of the blood and inhibits the action of *Brucella* opsonins which are present in the serum of many normal individuals.

Preparation of Blood Specimen. The blood specimens on which the test is to be made are collected in 5 c.c. amounts in glass vials in which has been placed 0.2 c.c. of a 20 per cent solution of sodium citrate in physiological salt solution. The final dilution of sodium citrate that obtains in the blood is 0.8 per cent. The test should be conducted on the specimens within six hours after collection provided they are kept in a cool place. The polymorphonuclear cells in blood disintegrate very rapidly when it is kept warm for two or three hours. The specimens should be thoroughly shaken directly before mixing with the bacterial suspension.

Bacterial Suspension. The bacterial suspension is prepared fresh each day by suspending several loopfuls of the

growth from a 48 hour liver agar slant culture in sterile physiological salt solution of pH 7. The turbidity of the suspension should give a reading of approximately 2 cm. when measured with the Gates apparatus.⁶ Suspensions of any of the three species of *Brucella* are suitable regardless of virulence.

The Test. Into clean small glass vials, such as are used for the agglutination or Kahn test, are placed 0.1 c.c. of the whole blood and 0.1 c.c. of the bacterial suspension. After mixing thoroughly, the vials are placed in an incubator for 30 minutes at 37° C. Certain strains of *Brucella* tend to become "fast" to ingestion by the cells after being transferred daily for many weeks. If a culture is being used daily for the test, it should be checked frequently for "fastness" to phagocytosis against whole citrated blood from a known immune person. Continuous agitation during the period of incubation tends to inhibit phagocytosis. Considerable sedimentation of the blood cells takes place during the incubation period. The cells should not be resuspended by shaking after the period of incubation. Directly after removing the tubes from the incubator, a small amount of the sedimented cells is removed by means of a finely drawn capillary pipette to which is attached a small rubber bulb. A drop of the cells is placed at one end of a thoroughly cleaned and polished glass slide, and drawn across the slide by placing the end edge of another slide at such an angle that the spread thins out and terminates at or near the middle. In a spread of this type, most of the leucocytes may be found near the terminating edge of the spread. The blood film should be dried as rapidly as possible to prevent shrinking of the leucocytes. Rapid drying may be obtained by placing the slides in front of a small electric fan. A small heating unit from an electric heater, if attached to the

front of the fan and operated simultaneously, will greatly increase the speed of drying.

Staining Spreads. The slides are placed face-upward on a suitable rack and the spreads covered with 0.5 c.c. of Hastings stain. After an exposure of 15 seconds, 1 c.c. of distilled water is added to the stain on the slide. At the end of 10 minutes, the spread is gently washed free from stain with distilled water and dried in front of an electric fan.

Estimation of the Degree of Opsonocytophagic Activity. The size of the organism in question and the marked degree of phagocytosis which occurs in cells from immunes has necessitated the employment of a different system of recording phagocytic activity from that which is commonly used in studies of this nature. In routine work, a total of 25 cells is counted in different sections of the spread and each cell is recorded as negative when no phagocytosis occurs, as slight when from 1 to 20 bacteria are seen in the cell, as moderate when from 21 to 40 bacteria are found in a cell, and marked when the number of bacteria in the cell is above 40. The bacteria are so numerous in those cells showing marked phagocytosis that it is impossible to count all of them. Examples of different degrees of phagocytosis of *Brucella* are shown in Plate I.

It is realized that the foregoing method of measuring degrees of phagocytosis is only approximate. It was adopted after making thousands of examinations by different methods.

Brucella Allergic Skin Test. The agent used in making the allergic test was developed by Hershey in our laboratory during his study of the chemistry of *Brucella*. It is a soluble nucleo-protein fraction of the three species of *Brucella* in 1-1000 dilution in slightly alkaline physiological salt solution. The test is made by injecting

*Slight**Marked**Negative**Moderate*

PLATE I

DEGREES OF PHAGOCYTOSIS OF BRUCELLA

about 0.1 c.c. of the fluid intracutaneously in the lateral surface of the forearm, using a 26 gauge needle. The size of the local reaction, which is characterized by a circumscribed erythema and slight edema, may vary from 1 to 2 inches in diameter and appears within 24 hours after injection. It may persist for 48 to 96 hours. There is no necrosis or sloughing of the tissue at the point of the local reaction. In the infected, the local reaction may be accompanied by a more marked manifestation of symptoms. Those that are hypersensitive will show a terrific symptomatic reaction along with the local reaction. Those that have not been sensitized to *Brucella* and who are probably susceptible to infection show no systemic reaction. Often

one sees in certain individuals an erythema, about one-half inch in diameter with no edema around the point of the injection. It has the appearance of a nonspecific reaction.

RESULTS OF STUDY

Results on Blood Specimens from Cases Diagnosed as Undulant Fever. Each of the 19 cases presented in Table I has shown clinical symptoms similar to those seen in acute and chronic undulant fever before a laboratory diagnosis of the disease was made. The laboratory diagnosis was based on either a positive blood culture or on the combined results of the agglutination, allergic and opsono-cytophagic tests. In the absence of a positive blood cul-

ture and positive agglutination test, the diagnosis was made on the basis of the results of both the allergic skin test and opsono-cytophagic test. No diagnosis was based on these two tests until sufficient data were accumulated from previous studies to warrant their application to the diagnosis of undulant fever.

The laboratory tests and allergic skin test were used in the diagnosis of the disease within a few days after the onset of symptoms in a few cases, while in others the interval varied from six weeks to approximately two years.

Brucella melitensis was isolated from the blood of cases Nos. 3, 14 and 15. These were laboratory infections. *Brucella abortus* was isolated from the blood of cases Nos. 5, 8, 9, and 13. Blood cultures from the remaining 12 cases were negative.

It may be noted from the data presented in Table I that the opsono-cytophagic power of the blood is low or

absent in all cases with the exception of No. 6. This individual had a comparatively mild form of the disease as expressed in terms of clinical symptoms. Experience with this test has shown that the phagocytic power rises and falls during the course of the disease. If the invading organism is very active in the body, the phagocytic activity of the cells is likely to be low. On the other hand, if it is not very active, as indicated by clinical symptoms, the phagocytic activity of the cells will be found higher.

In view of the fact that many individuals, either healthy or ill, will show an allergic skin reaction to *Brucella* due to previous infection, one might question a diagnosis of undulant fever based on a positive allergic skin test and low or negative opsono-cytophagic test in a patient in the absence of a positive blood culture and negative agglutination test. We have given considerable attention to this question in our studies.

The contention that a diagnosis of undulant fever can be made on the basis of the two tests in question is supported by the data which are to follow concerning the degree of ingestion of the organism on the part of the cells in blood examined shortly after and long after recovery from the disease, as compared to that which takes place in the blood from patients during the course of the disease. Furthermore, it is supported by the fact that those cases in question respond to specific treatment with either Brucellin or Pyronin, or both, when administered simultaneously and the cells in whole citrated blood show marked phagocytosis of Brucella.

Comparisons of the Results of Blood Examinations Made on Patients During and After Recovery from Undulant Fever. The comparative results are illustrated in Table II on eight known cases of undulant fever. The opsono-cytophagic test was made during the disease from two days to two months after the onset. The time of making the test on each case after recovery, varied from two days to approximately one month. The evidence on which recovery from the disease is determined is the complete disappearance of all those clinical symptoms by which it is characterized.

The data clearly show that the opsono-cytophagic power of the blood is low during the disease and becomes very marked after recovery.

Results of the Examination of Blood from Individuals Known to Have Had Undulant Fever. In Table III are illustrated the results of the opsono-cytophagic test and agglutination test on 15 individuals after recovery from undulant fever. These cases are not included in the group in Table II. The tests were made at intervals varying from 36 days to four years after recovery from the disease.

The opsono-cytophagic power of the blood for Brucella is very marked in all cases, regardless of the length of the interval between recovery and the phagocytic examination. It is interesting to note that there is no relation between Brucella agglutination titer of the individual's serum and the ingestion capacity for Brucella of the leucocytes suspended in the serum.

All individuals whose blood shows a marked opsono-cytophagic power for Brucella *in vitro* similar to that in those cases illustrated in Table III, will also show an allergic skin reaction to the same degree as those that are infected with Brucella when tested by a satisfactory Brucella allergin. The blood of the infected, however, will not show

marked phagocytic power for *Brucella in vitro*.

Results of the Examination of Specimens of Blood from Bacteriology Laboratory Workers. In Table IV are presented the results of the opsonocytaphagic and agglutination test in three groups of laboratory workers; namely, those who have been working with infective material for several years, those who have never knowingly handled infective materials, and a group before and after working with infective materials. Cases No. 1 and 2 represent the latter named group. The blood of these two individuals showed no phagocytic activity for *Brucella* before working with infective materials or infected animals. At some period within four months after beginning their laboratory work, both were infected with *Brucella*, as indicated by the results of the blood examinations. There was no clinical evidence of the disease in either case.

Those that have never knowingly worked with infective materials or infected animals are Nos. 6, 10, 12, 18, 19, and 20. The remainder of the group are known to have worked with cul-

tures of the organism or infected animals. The blood of each of the latter, twelve in all, with the exception of one, shows a very marked phagocytic activity for *Brucella*.

In Table V are presented data on 17 packing house employees, to support the contention that those who are exposed constantly to *Brucella* infective materials or to *Brucella* infected animals will sooner or later become infected. The blood of these men was examined on November 11, 1931, with negative results to both the agglutination and opsonocytaphagic tests. One of the men in this particular group, engaged in the manufacture of sausages, developed clinical undulant fever in June, 1932. An examination of the blood of each, including the one, No. 17, who was showing symptoms typical of the disease on July 22, 1932, revealed valuable information pertaining to *Brucella* infection and immunity. The results of the agglutination test show that eleven had been exposed to infection; that is, the organism had passed beyond the epithelial barrier of the skin or mucous membranes. The opsono-

cytophagic test was conducted on all except two. The results of this test showed that all those reacting to the agglutination test and two others that were negative had been exposed to infection. The blood of those, Nos. 2, 8, 9, 11, and 17, which were showing symptoms of the disease, had low phagocytic power for *Brucella*. The phagocytic power of the cells was either marked or negative in those showing no symptoms of the disease. *Br. suis* was isolated from the blood of No. 11.

The Results of the Examination of Blood Specimens from Large Groups of Individuals. The groups in question were veterinarians, packing house employees, college students enrolled in bacteriology courses, hospital patients and inmates of a State Prison.

The gross results of the opsono-cytophagic test and agglutination test for *Brucella* are presented in Table VI. Most of the 20 veterinarians examined had been engaged in cattle practice. The opsono-cytophagic power of the

blood from 19 was very marked for *Brucella*. None gave a history of having clinical symptoms characteristic of undulant fever. Many of them, however, report the appearance of an erythema on their arms after removing retained placentas from aborting cows. This sign indicates hypersensitiveness to *Brucella*. The skin test is always positive in such cases.

Blood specimens were taken from 176 men and women in three packing houses and one stock yard in Michigan. Most of the men were engaged in work which necessitated the handling of fresh pork or beef. The women were employed in wrapping cured bacon for the market. The stock yard employees came in contact with live animals only. The results of the opsono-cytophagic test alone indicate that 40, or 22.7 per cent, of the employees have at some period in the past been infected with *Brucella*. Of the total examined, three were showing clinical symptoms of

TABLE VI
OPSONO-CYTOPHAGIC POWER OF BLOOD OF GROUPS OF INDIVIDUALS

| Group | Number Examined | Date of List | Opsono-Cytophagic Test | | | Agglutination Test | Estimated Per Cent Exposed to Brucella Infection |
|-------------------------|-----------------|----------------|------------------------|------------------|--------------------|---|--|
| | | | Number Showing | | | | |
| | | | All Cells Marked | Few Cells Slight | All Cells Negative | | |
| Veterinarians | 20 | 6/20/31 | 19 | 0 | 1 | Titers, varied from negative to + 1/500 | 95 |
| Packing House Employees | 176 | 11/12/31 | 40 | 47 | 89 | Titers, varied from negative to + 1/500 | 22.7 |
| College Students | 29 | 5/10/31 | 5 | 9 | 15 | Titers, negative to incomplete 1/25 | 17.2 |
| Hospital Patients | 240 | During 1931-32 | 30 | 45 | 165 | Titers, varied from negative to + 1/50 | 12.0 |
| Men in State Prison | 133 | 7/22/32 | 14 | 26 | 97 | Titers, all negative except one + 1/500 | 10.5 |

undulant fever at the time the blood specimens were collected.

The 29 college students were in two separate groups, one of which was examined about one year after the other. Of the total number examined, the blood of 5, or 17.2 per cent, showed the degree of phagocytosis observed in those who have at one time been infected with Brucella.

The hospital patients from whom

blood specimens were examined constituted a rather miscellaneous group of both males and females. They might be grouped as cases of infectious and organic disease, injuries, and blood donors from whom blood is taken for transfusion. Of the total number examined, the blood of 30, or 12 per cent, showed the degree of phagocytosis observed in those who have at one time been infected with Brucella.

TABLE VII

A. PROPOSED SYSTEM FOR THE DIAGNOSIS OF UNDULANT FEVER ACCORDING TO RESULTS OF THE AGGLUTINATION, ALLERGIC AND OPSONO-CYTOPHAGIC TESTS

| Agglutination Test | Allergic Skin Test | Opsonophagic Power of Blood | Status Toward Brucella |
|--------------------|--------------------|--------------------------------------|------------------------|
| — | — | Cells negative to 20 per cent slight | Susceptible |
| — | + | Cells negative to 40 per cent marked | Infected |
| — | + | Cells 60 to 100 per cent marked | Immune |
| + | + | Cells 60 to 100 per cent marked | Immune |
| + | + | Cells negative to 40 per cent marked | Infected |

The prison inmates examined were of two groups, namely, kitchen personnel and patients in the tuberculosis hospital. The latter group may be divided into diagnosed cases and suspects. Of those examined, the blood of 14 or 10.5 per cent, showed a marked degree of phagocytosis for *Brucella*. These men came from all walks of life and should represent a cross section of what one would expect to find from an examination of the blood of the general population. Patients examined in the hospitals and students also represent a cross section of the general population.

DISCUSSION

We present data on an opsonocytophagic study of the whole citrated blood of humans with respect to *Brucella* infections. A technic for testing the opsono-phagocytic power of the whole blood and a reagent and procedure for making a satisfactory allergic skin test are described. The two tests should be made simultaneously in determining the status of an individual as respects *Brucella* infection. The data have furnished a basis for measuring susceptibility, infection and immunity to *Brucella* infection.

The advantage of using whole blood in such studies has been pointed out by Shattock and Dudgeon,⁷ Hektoen⁸ and many others. The addition of sodium citrate to the blood serves a twofold purpose, namely, to prevent clotting and partially or totally to reduce the opsonic property of the serum in order to ascertain variations in the phagocytic power of the blood.

The basis for the assertion that the measurement *in vitro* of the opsonocytophagic power of whole citrate blood of humans in conjunction with the determination of skin allergy for *Brucella*, will determine susceptibility and immunity to, as well as infection with *Brucella*, rests upon the data which we have gathered. Although our data with

respect to phagocytic activity of the blood in *Brucella* infection in man is new, it might be said here that many investigators have collected similar data from the study of other infectious diseases of man and animals. The interpretations which they have given to their results differ somewhat from those placed on our own. For example, a continuous high phagocytic power of the blood for an organism has been interpreted as meaning a "carrier state," by certain workers. Ledingham,⁹ Gaehlgens,¹⁰ Hamilton,¹¹ and others have observed that sera of typhoid carriers invariably show a high opsonic index when compared with the normal individual. Such findings have been considered useful in detecting the typhoid carrier. If the high phagocytic power of the blood seen in those who recover from undulant fever as well as many other individuals who give no history of the clinical manifestations of the disease, is taken as evidence of a carrier state as it is in typhoid, then there is a large group of individuals in this country who are constantly carrying *Brucella* in some part of their body. The data that we have accumulated on blood specimens from humans do not indicate that a continuous high phagocytosis for *Brucella* signifies a carrier state.

The observations which we have made over a period of years on the value of the intradermal test for detecting *Brucella* infection in humans convince us that a positive reaction does not necessarily mean active infection. A positive reaction signifies sensitization to *Brucella*. If a positive skin reaction is obtained in doubtful cases of undulant fever, the positive reaction does not have specific significance until a determination of the opsono-cytophagic power of the whole blood is made. The latter test should be made at the same time or before the skin test is performed.

In order that the interpretation of the combined agglutination, opsonocytaphagic and allergic tests may be clarified as respects the status of a given individual toward *Brucella* infection, we are proposing a system of diagnosis according to the combined results of the three tests. The proposed system is arranged in Table VII.

In any study which concerns the phenomenon of phagocytosis there always appear many problems and questions that need solving and answering. We have studied at considerable length the factors involved in bringing about the phagocytosis of *Brucella* in human blood and blood from other species of animals as well. We have also made some very interesting observations on the opsonocytaphagic power of the cord blood from infants and blood from new born calves before and after the ingestion of colostrum. These studies together with a considerable number of other observations will appear in a forthcoming paper.

SUMMARY

The studies which we have conducted on citrated blood of humans who were known to have had undulant fever in past years and shortly after recovery, who are actively infected, or who have no history of the disease, show that the *in vitro* activity of the polymorphonuclear cells in whole citrate blood for *Brucella* is an expression of immunity to *Brucella* and an indication of the progress toward recovery in active infection. The ab-

sence of or a low phagocytic activity obtained in conjunction with a negative allergic skin test is evidence of susceptibility to *Brucella* infection. Infection in an individual is indicated by a positive allergic skin test obtained with *Brucella* nucleo-protein in conjunction with negative or low opsonocytaphagic activity of the whole citrated blood for *Brucella*.

Toxicity of Organic Fluorides*

WILLIAM P. YANT

*Supervising Chemist, Health Laboratory Section, Pittsburgh Experiment Station,
U. S. Bureau of Mines, Pittsburgh, Pa.*

THIS paper presents a résumé of the toxicological properties of two compounds — namely, dichlorodifluoromethane and dichlorotetrafluoroethane — that have been developed in the course of a search for safe refrigerants.¹ The toxicological investigation was made by the Bureau of Mines with the coöperation of the Frigidaire Corporation, the Bureau of Mines interest being inherent in the problem of safety in conditioning the air of mines where the high temperature and humidity present an unhealthy environment for workmen and in some cases are an impediment if not a barrier to mining operations.

At the present time there is much interest in and endeavor toward increasing health and safety in domestic and industrial refrigeration. The effort is aimed not only at betterment of present appliances and the solution of present problems but also at the solution of problems which are anticipated in the extension of refrigeration, particularly for conditioning the air of homes, public buildings, and working places. In some instances the endeavor is directed toward safer means for using a product that is potentially or has been in fact a source of trouble, as: better mechanical construction; means for apprising persons of leakage; using refrigerants that permit lower operating pressures, possibly even below atmospheric pressure; limiting the quantities of refrigerating media used and hence the

potential magnitude of exposure of persons; and regulations pertinent to the installation of the devices. In other instances the endeavor has been not only to prevent exposure but also to develop refrigerating media of a safer nature.

PHYSICAL AND CHEMICAL PROPERTIES²

Dichlorodifluoromethane² (CCl_2F_2) at room temperatures and pressures is a heavy, colorless gas that possesses a chloroform-carbon-tetrachloride-like odor.* The boiling point is -29.8°C .; density of liquid, 1.35 gm. per c.c. at 13.8°C .; specific gravity of gas (air = 1), approximately 4.2; vapor pressure in atmospheres, 3.045, 5.592, and 11.99 at 0° , 20° , and 50°C ., respectively. It is non-flammable, non-corrosive, and neutral. Solubility is estimated as 0.03 gm. in 100 gm. of water. The operating pressures of refrigerating devices using this compound would be in the general range of those for sulphur dioxide and methyl chloride.

Dichlorotetrafluoroethane² ($\text{C}_2\text{Cl}_2\text{F}_4$) at room temperatures is a heavy, colorless gas that possesses a sweet chloroform-like odor.* The boiling point is 3.6°C .; density 1.4 gm. per c.c. at 15°C .; specific gravity of gas (air = 1), approximately 5.9. It is non-flammable, non-corrosive, and neutral. Solubility is estimated as 0.1 gm.

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27, 1932.

* As this work was performed while these products were in the semi-commercial stage of production, the products may have contained traces of impurities which contributed to the odor.

in 100 gm. of water. The physical properties of this compound permit its use in refrigerating appliances designed for operation at nearly atmospheric pressure, thereby minimizing the possibility of leakage.

EXPERIMENTAL PROCEDURE AND APPARATUS

The reader is referred to progress reports on the toxicity of these compounds^{3, 4} for a detailed description of the test equipment and procedure. It may be briefly stated here that the experiments were conducted under carefully controlled conditions. The concentration of vapor was recorded continuously during all experiments by means of a thermal conductivity gas-analysis apparatus, and the oxygen and carbon dioxide content was ascertained by volumetric gas analysis procedures. Control animals were simultaneously exposed to identical conditions except that the air lacked the vapor.

RESPONSE OF ANIMALS TO DICHLORODIFLUOROMETHANE

Repeated Exposure of 7 to 8 Hours Daily to 20 Per cent CCl₂F₂ in Air—

Dogs and monkeys* were exposed to air containing 20 per cent by volume of CCl₂F₂ for 7 to 8 hours daily on five days, and for 4 hours on the sixth day of each week during a 12-week period. This exposure produced mild to moderate to marked generalized tremor in dogs, and mild to moderate generalized tremor in monkeys. The tremor was recurring and cyclic, each cycle ranging from a fine tremor when the animal was quiet to a marked coarse tremor, often convulsive, when there was attempted activity. When the animals, particularly the dogs, attempted to walk, they

acted very much like persons suffering from alcoholic ataxia. They reacted to light and stimuli, and did not become unconscious. The maximum severity of symptoms was reached in the first 10 to 20 minutes of an 8-hour exposure. The symptoms practically disappeared in 1 minute and completely disappeared in 10 minutes after removal from the test environment. In most instances the animals ate food offered to them during exposure and always had good appetites in 5 to 10 minutes following a daily exposure period. A tolerance was developed with successive daily exposures. This was manifested by a marked decrease in severity of the symptoms. No fatalities occurred.

The number of red blood cells and the hemoglobin content increased slightly during the first two or three weeks of the series of exposures but thereafter was normal and similar to control animals. There was also a slight increase in the polymorphonuclear neutrophils with a slight decrease in lymphocytes.

Autopsies performed on all animals revealed no gross pathology attributable to the exposure to dichlorodifluoromethane.

The persons that performed these experiments were momentarily exposed on many occasions to the experimental environment. It produced distinct eye irritation and immediate symptoms of vertigo. These symptoms disappeared in a minute or two after exposure. The character of the atmospheres is such that persons would not voluntarily tolerate it.

*Continuous Exposure (24 Hours Daily) to 20 Per Cent CCl₂F₂ in Air—*Monkeys exhibited signs of irritation of the eyes and slight incoördination during the first 9 to 14 hours and were, in general, sluggish and drowsy with incoördination after 18 hours, though at times they became very alert and active. The periods of activity were followed

* Guinea pigs were also used in this study, but owing to the desirability of condensing this paper the results are confined to those obtained on dogs and monkeys. The work with guinea pigs has been described in previous publications.^{3, 4}

by periods of marked sluggishness and drowsiness. This condition prevailed without occurrence of unconsciousness during continuous exposure periods up to 121 hours and 24 minutes. No deaths occurred during or following these exposures. Gross autopsy findings were slight congestion, particularly in the lungs, and appearance of slight fatty degeneration of the liver.

A dog exhibited signs of irritation of the eyes, generalized tremor and marked incoördination in a few minutes, and incoördination to the point of falling after an hour and 20 minute exposure. Tremors increased in severity during the following three hours, and at times there was a pronounced jerking of the head. Also during this time unsuccessful attempts were made to stand. However, following these observations the animal began to show tolerance; the tremors were less severe, the dog was able to stand, and he ate food. The remainder of a continuous 121 hour and 24 minute exposure was characterized by signs of weakness and somnolence with periods of apparent normalcy. After termination of exposure the symptoms abated in a few minutes. This animal was observed for 28 days following termination of exposure and then killed for autopsy while in an apparently healthy condition. Gross autopsy findings were signs of a previous irritation of the lungs and the liver was pale; otherwise the organs appeared normal.

EXPERIMENTS WITH DICHLOROTETRA- FLUOROETHANE ($C_2Cl_2F_4$)

The experiments with dichlorotetrafluoroethane ($C_2Cl_2F_4$) were performed in the same apparatus and according to the same technic as those with dichlorodifluoromethane.

Exposure to 20 Per Cent $C_2Cl_2F_4$ in Air—In general the symptoms were very similar to those produced by

dichlorodifluoromethane. Exposure of dogs to 20 per cent vapor caused immediate and continued marked generalized tremors and recurring convulsions with periods of relaxation and exhaustion. Recovery was rapid and complete after a single 8-hour period; death occurred in seven days following a single exposure of 16 hours, and in three days following a single exposure of 24 hours.

Repeated exposures of eight hours daily produced immediate marked generalized tremors and convulsions, and death after 3 to 4 daily periods.

The number of red blood cells, hemoglobin and the younger forms of polymorphonuclear leucocytes invariably increased in the general order of the severity of the exposure. There was usually a slight to moderate decrease in platelets. Other blood findings were of no particular significance. A tendency toward a slight increase in red blood cells, hemoglobin and the younger forms of polymorphonuclear leucocytes was also noted in the control dogs, but this change was slight in comparison to that observed in the exposed animals. The changes observed in the blood counts of the exposed dogs, although possibly influenced by the decrease in oxygen, caused by dilution of the air with the dichlorotetrafluoroethane vapor, were undoubtedly due to some extent to $C_2Cl_2F_4$.

Congestion throughout all of the organs was the most definite gross pathological finding in all dogs that died. This was particularly noted in the lungs with areas of hemorrhage, and in the gastrointestinal tract.

Exposure to Approximately 15 Per Cent $C_2Cl_2F_4$ in Air—In view of the fact that the response to 20 per cent $C_2Cl_2F_4$ was more severe than the response to a similar volume concentration of CCl_2F_2 , the concentration used for succeeding experiments was 14.16 to 15 per cent vapor by volume. On a

weight basis a 14.16 volume concentration of $C_2Cl_2F_4$ is equivalent to a 20.0 per cent. by volume concentration of CCl_2F_2 . Also the fluorine present (by weight) is equal in these comparative volume concentrations.

Exposure to 14.16 or 15 per cent vapor in air caused moderate to marked incoördination with generalized tremors in dogs, and occasional convulsions, the symptoms again being similar to those previously described for CCl_2F_2 . After three to five consecutive 8-hour daily exposures to 14.16 per cent a tolerance gradually developed, convulsions disappeared and tremors became finer or disappeared entirely. There was a slight loss of appetite and weight during the first five days of exposure but this was regained with succeeding exposures and was maintained. No deaths occurred during 21 consecutive exposures or during a 15- and 17-day post-exposure observation period. Exposures to 15 per cent vapor in air for a single period of 16 or 24 hours caused temporary loss of appetite but no deleterious effects of a permanent nature were observed.

Eight-hour exposures for 21 consecutive days produced a slight gradual increase in hemoglobin and red blood cells. This returned to normal in 15 to 17 days after exposure. The younger forms of polymorphonuclear leucocytes increased during the first week of exposure but returned to normal with succeeding exposures. There was a slight decrease in platelets in one animal during the first part of the series but they returned to a normal number with succeeding exposures; the other dog showed no change in platelets.

No gross pathology was found in dogs repeatedly exposed 8 hours daily for 21 consecutive days; a slight congestion of the gastrointestinal tract was found in a dog continuously exposed for 24 hours to 15 per cent of gas, and a gastroenteritis in a dog continuously

exposed for 16 hours to 15 per cent. This was at first thought to be due possibly to secretion of dichlorotetrafluoroethane into the gastrointestinal tract, but on further consideration it appeared that the recurring convulsions that accompanied exposure were a more logical cause.

DISCUSSION OF TOXICITY OF ORGANIC FLUORIDES IN RELATION TO FUNDAMENTAL TOXICOLOGY

Aside from the primary interest of enhancing safety in refrigeration and air conditioning, these organic fluorides are very interesting from the viewpoint of fundamental toxicology. On the basis of former knowledge of the physiological response to volatile halogen derivatives of aliphatic hydrocarbons, as methyl chloride (CH_3Cl), chloroform ($CHCl_3$), carbon tetrachloride (CCl_4), and tetrachloroethane ($C_2H_2Cl_4$), and the comparative toxicity of inorganic chlorides and fluorides, it would generally be expected that the substitution of fluorine atoms for hydrogen or in part for chlorine atoms in the molecule would increase the toxicity. However, a comparison of the observed response to dichlorodifluoromethane (CCl_2F_2) and dichlorotetrafluoroethane ($C_2Cl_2F_4$) with response to the previously mentioned compounds will show that the response to these fluorine-containing derivatives on the basis of concentrations in the air by volume is phenomenally less than would be expected. The effective concentrations are of an entirely different magnitude, being roughly 50 to 100 times those of the previously mentioned group.

The wide difference in toxicity between these aliphatic fluoro-chloro compounds and aliphatic chloro compounds brings to attention the need for more fundamental information on these subjects and points out the potential value of such information to the selection and development of safer chemical com-

modities. An obvious suggestion is the development of a non-flammable gaseous anesthetic with a low toxicity.

SUMMARY

The results of exposure of dogs and monkeys to dichlorodifluoromethane and dichlorotetrafluoroethane vapor in air shows that the toxicity of these chemicals is very low.

Concentrations of 20 per cent CCl_2F_2 by volume produce marked objective symptoms during exposure but they disappear very rapidly after termination of exposure, and no distinct harm is evident after many repeated exposures of eight hours daily. Exposure to 20 per cent vapor in air continuously for 121 hours also produced marked symptoms but did not cause unconsciousness or death.

Concentrations of 14 to 15 per cent $\text{C}_2\text{Cl}_2\text{F}_4$ by volume produce marked objective symptoms during exposure, but they disappear very rapidly after termination of exposure. No distinct harm is evident after as many as 21 consecutive exposures of eight hours daily. Twenty per cent concentrations or longer exposures daily produce evidence of harm. It is evident that on the basis of equal concentrations in air $\text{C}_2\text{Cl}_2\text{F}_4$ is distinctly more harmful than CCl_2F_2 but is of the same low order of relative toxicity when comparison is made with gases that present public or industrial health hazards.

The odor intensity and irritative

properties of both CCl_2F_2 and $\text{C}_2\text{Cl}_2\text{F}_4$ are high enough to give distinct warning of their presence in concentrations far below those that produce death.

It may be added that the experiments described in this report were performed with a supply of material produced by a semi-commercial plant. It is very possible that small amounts of other halogenated hydrocarbons may have been present. It is known⁵ that certain other chloro-fluoro hydrocarbon derivatives have a higher order of toxicity than CCl_2F_2 and $\text{C}_2\text{Cl}_2\text{F}_4$, and considering the high concentrations of CCl_2F_2 and $\text{C}_2\text{Cl}_2\text{F}_4$ used in the experiments, the presence of fractional percentages of other compounds could have been responsible for a considerable part of the observed response.

The Incidence of Xerophthalmia and Night-Blindness in the United States— A Gauge of Vitamin A Deficiency

ALFRED F. HESS, M.D., AND DANIEL B. KIRBY, M.D.
New York, N. Y.

ALTHOUGH we have acquired a considerable fund of knowledge in regard to the vitamins and collected satisfactory data as to their distribution among the various foods, the question is still mooted as to whether there is a sufficiency of these essential food factors in the American dietary. This question is particularly acute in regard to the adequacy of vitamin A in the diet of both children and adults. In view of the importance of this subject and what we believe to be an exceptional opportunity for its elucidation, we decided to carry out a survey of the clinical evidence of early vitamin A deficiency in cities of the various sections of the country.

As is well known, a lack of vitamin A, which has unfortunately been given the titles "the ophthalmic vitamin," "the growth vitamin" or "the anti-infective vitamin," is manifested in young children and infants by a pathologic lesion of the eye which, according to the degree of severity, is designated as xerosis or xerophthalmia. In adults, we are exceptionally fortunate in being able to recognize the deficiency of this vitamin by the occurrence of a disturbance which is functional rather than organic, namely, night-blindness or nyctalopia. This defect of vision is evidenced by inability to see at night, due to the failure of dark adaptation of the retina; the

affected person may simply note a slight dimness of vision or the lack of vision may be extreme so that he is unable to find his way about even in moderate darkness. In order to ascertain the incidence of these two deficiency manifestations a questionnaire was sent to some 50 leading ophthalmologists in the United States, based on membership in the American Ophthalmological Society, inquiring how often they had encountered moderate or severe cases of xerophthalmia or cases of night-blindness in the course of their private practices. Information was also asked in regard to whether cases of this kind had become more frequent in the course of the current economic depression. Forty-one eye specialists have been kind enough to answer our queries and it is on the basis of such information that we have prepared this short report.

Of the 41 physicians, distributed from the east to the west coast and from Maine to Florida, 11 had not met with cases of xerophthalmia. Most reported having seen but 1 or 2 cases and stated that they regarded the disease as rare. Only 1 is of the opinion that "mild cases are not very rare," adding: "No survey is available at the present time on the incidence of xerophthalmia in this country. As a matter of fact, there are only 12 cases reported in the American literature on this subject. In

our community my attention has been called to 5 cases of xerophthalmia in the last 15 years." This was the greatest

number anyone had observed. One wrote, "I have had only 1 case in my practice. This man ate practically

nothing but potatoes." References to a marked restriction of the dietary due to some gastrointestinal disorder or to faddism, were not infrequent. All in all, there is unanimity as to the infrequency of xerophthalmia.

Although cases of xerophthalmia had been reported from time to time, it was not until the period of the World War that this disorder was thrust upon our attention. During the war Denmark exported most of her butter and fed her infants and young children milk which had been skimmed. Before long a disease of the eyes developed among the young. In the 86 cases reported by Bloch,¹ 47 developed this disorder during the first year of life and 20 of these during the first six months. Of Blegvad's² 430 cases of keratomalacia, 368 occurred during the first year, the majority in the second quarter; 62 were seen during the second year of life. These figures indicate the marked susceptibility of infants to this disease and, incidentally, their exceptionally high requirement of this vitamin. Among a group of children given whole milk, Bloch found that no instance of eye disease developed. In general, this has been the experience where xerophthalmia has been noted; in fact, no one has reported its development on an average dietary in a normal child. In almost every instance the diet has been exceptionally and preëminently defective. For example, Pillat,³ who has contributed so greatly to our knowledge of this subject, and has reported its frequency in China among the soldiers, states that they ate "only rice, corn, millet, very little flour; once a month a small quantity of meat and no green vegetables whatsoever. Almost no fat was used for cooking." A similar comment has been made in a recent account of xerosis in Tientsin where the diet of the infants consisted of rice water or condensed milk, and that of the adults of bread, rice or

vegetable water and salted cabbage or turnips.⁴ Probably the condensed milk was given greatly diluted. Aykroyd,⁵ who has published an interesting account of the development of xerophthalmia among the fishermen in Labrador, states that their diet consisted mainly of white bread, molasses, fresh cod fish, salt meat, beans, peas, some potatoes, but no milk, butter, eggs or green vegetables.

In regard to the effect of the economic depression on the incidence of xerophthalmia, the answers, without exception, were to the effect that this condition had not brought about a noticeable increase. Gifford, of Chicago, who has reported cases of xerophthalmia, wrote: "I have really seen very little of this disorder in spite of the depression and I have been on the watch for it." Bedell, of Albany, who has also contributed to the literature on this subject, answered as follows: "Strangely enough I am seeing fewer of these cases at this time than ever, so that the depression has not had any effect in increasing their incidence." This evidence from those who would be expected to see cases of this description is substantiated by the fact that in the Quarterly Index of medical literature for the latter half of 1932, no instance of xerophthalmia is reported from the United States. Although references to night-blindness have been recorded in previous volumes of the Quarterly Index, this disorder is entirely omitted from the latest volume.

The other clinical evidence of a deficiency of vitamin A, night-blindness, can be elicited only in older children or in adults. This sign gains added significance from the fact that it is functional, unaccompanied by ophthalmoscopic evidence, and that it is quickly, almost miraculously, remedied when the dietary is fortified with vitamin A. For example, 1 or 2 teaspoonfuls of cod liver oil will often cure

the condition from a functional standpoint within 24-48 hours. In this symptom we possess the most delicate of all indicators for vitamin deficiency; in relation to no similar disorder have we as yet a sign or test which is unaccompanied by pathologic change. Among the 41 answers only 8 cases of night-blindness were reported by the various specialists, 1 writing that he had met with 3 instances in the past 2 years. That night-blindness is due to a lack of vitamin A was proved in 1925 by the interesting experiments of Fridericia and Holm,⁶ who showed that the visual purple of the retina, after exposure to strong sunlight, was particularly slow to regenerate in rats which had been on a diet devoid of vitamin A. The biologic experiments of Yudkin and his coworkers⁷ indicate that the retina is exceedingly rich in vitamin A. Indeed Yudkin found, according to a later report,⁸ that the retina of the hog is richer in vitamin A than is butter-fat, although the choroidal tissue is almost devoid of it. It may be stated without fear of controversy, that night-blindness is a rare disorder in the United States and that most of the reports of this disturbance emanate from countries where there has been famine or a marked deficiency of food. Without entering into detail, it may be stated that a review of those cases which have been reported from the United States and Europe shows that, as in the case of xerophthalmia, they have been occasioned by either a notable defect in diet due to idiosyncrasy or by some condition which induced a lack of utilization of the food. Drunkards are especially susceptible. A report of the Copenhagen Poor Law Institution states that 45 per cent of the 312 inmates were found to suffer from

night-blindness and that this disorder followed the consumption of corn brandy.⁹

CONCLUSION

A formal inquiry carried out among the leading eye specialists throughout the United States may be summarized by the statement that xerophthalmia is of rare occurrence in this country and that night-blindness is even more exceptional. Furthermore, it is the consensus of opinion that there is no indication whatsoever that either of these diseases has increased in frequency during the economic depression. As both of these disorders are the result of a deficiency of vitamin A, it would seem as if a lack of this vitamin among the child and adult populations is extremely uncommon. This conclusion is all the more warranted in view of the fact that night-blindness is a very early and purely subjective symptom of vitamin A deficiency, occurring before any ophthalmoscopic evidence or microscopic lesion can be noted in the retina.

A Modified Quevenne Lactometer for the Public Health Laboratory Control of Market Milk*

R. V. STONE, F.A.P.H.A.

*Director of Laboratories, Los Angeles County Health Department
Hall of Justice, Los Angeles, Calif.*

THE Dairy and Milk Laws of the State of California require that at least two street samples of market milk be collected every month from delivery wagons, these samples to be routinely subjected to the standard plate count, to a test for butter fat, for the amount of sediment and for the solids not fat.

Although the Standard Methods of the A.P.H.A. and A.O.A.C. are the official methods for practical reasons the Babcock test and the lactometer are used throughout the State for the fat determinations and for computing the solids not fat. Actual extraction and gravimetric determinations cannot be conducted in the average laboratory because of the time involved in such determinations. Where milk work alone is handled by a laboratory, the Majonnier and chemical analysis is possible; but milk work in California public health laboratories constitutes only one of many widely variegated procedures, all of which is conducted frequently by but one or two State authorized bacteriologists. Most of such laboratories do not employ a specialist in chemistry.

Accordingly, the lactometer has carried a great deal of responsibility in such work and because accuracy in

these instruments varies with the extent of range that the stem includes, it was true that the same distributor's milk tested on the same day in two or more neighboring health department laboratories did not give comparable findings as regarded solids not fat. This led to dissatisfaction on the part of dairymen and others, and the laboratory was blamed for inaccuracy of technic when, as a matter of fact, physical equipment that was not standardized for accuracy was to blame.

A state law considers an 8.7 per cent solids not fat as a full score milk; whereas a milk below 8.5 per cent solids not fat is illegal. The Los Angeles County Health Department Laboratories was authorized by the County Health Officer (Dr. J. L. Pomeroy) to investigate existing conditions that appeared to be working certain injustices to the dairy industry.

It was soon established that a variety of instruments were in use throughout the state, the length ranging from 6 to 9, to 10 or 12 inches. The length of graduation between 14 to 42 Quevenne degrees varied from $1\frac{1}{2}$ to $4\frac{1}{4}$ inches. Some instruments contained thermometers as a part of the whole; some were for "pure" milk and skim milk in one instrument. A considerable number of instruments of cheap foreign manufacture were in use.

* Discussed before the California Association of Dairy and Milk Inspectors, at San Bernardino, Calif., on October 9, 1928, and at Oakland, Calif., on October 9, 1929.

These did not have a manufacturer's name on them and seldom checked one against another.

Some instruments were recommended to be read at the *top* of the meniscus while others were to be read at the *surface* of the liquid. Such recommendations were on the slip of paper packed in the instrument—not on the instrument itself. Such a record was soon divorced from the instrument itself so that an operator not knowing the manufacturer's design would proceed as in the usual spindle reading and record the specific gravity as that where the surface of the liquid cut across the stem. This permitted of errors of one full degree or more dependent upon the spacing of the degree graduations on the stem. Since one degree is equivalent to .25 per cent of solids not fat, such an error could throw a fully legal 8.7 per cent milk into an illegal 8.45 per cent solids not fat. Conversely an illegal milk could be thrown into a fully legal milk if the reading was made at the surface of the liquid on a "top of meniscus" standardized lactometer.

The retail price of these various types of lactometers ranged from \$1.25 to \$5.00. When one considers the relatively high price precision instruments demand, it should be recognized that the cheaper instruments could not possibly be depended upon.

American manufacturers generally devote care in the products they are to sell, and such were certainly much more comparable in the reading of more than one instrument on the same milk than were the cheap "flood" of imported stock. However, it is doubtful that any of them expected that an instrument selling for a relatively low price (compared with laboratory equipment generally) would be absolutely accurate for whole milk, skim milk, and for temperature.

In answer to a written inquiry from us, Ernest Kelly replied:

I have your letter of the thirteenth regarding the method of reading lactometers. There is a considerable diversity in this practice in various places. I took the matter up with the Bureau of Standards some time ago and found that they read to the top of the meniscus when standardizing lactometers that are sent in to them. This being the case, it is apparent that lactometers which have been standardized by the Bureau of Standards should be read to the top of the meniscus. I do not understand just why lactometers should be standardized in this way. It seems that there should be a good deal of work done to check up this method with specific gravities determined by other methods.

With the ordinary lactometer the difference between the top of the meniscus and the surface of the liquid is approximately one degree. This would make a difference of about .25 per cent in solids not fat as calculated, so that if there is not a standard method of reading the lactometer there would be an unfortunate variation in calculating the solids.

It is obviously impossible to read the lactometer at the exact surface level of the liquid. I have usually read the lactometer at the point where the scale is plainly visible through the meniscus. However, if all lactometers are standardized to the top of the meniscus, that is the place where readings should be made.

A letter from the referee for the Association of Official Agricultural Chemists written by Dr. Robert S. Breed under date of April 26, 1927, said:

I find on looking up the methods of the A.O.A.C. that they recommend that specific gravities of milk be determined by the use of the pycnometer. The lactometer method is a rough and ready method satisfactory for certain purposes but is not sufficiently accurate to have received the approval of this Association. The Westphal balance method is likewise accurate and perhaps more convenient than the pycnometer.

EXPERIMENTAL WORK

Milk was used rather than standardized solution, in making our comparisons. Pycnometer determinations were used to adopt a standard. Against such readings various lactometers were used for tests upon the same market milk. Eighteen foreign imported lactomet-

FIGURE I

This as a whole shows actual comparison in length by inches of the three lactometers worked with extensively.

A is the U. S. Department of Agriculture lactodensimeter.

B is the usual lactometer seen in use by dairy laboratories. It combines temperature, pure milk, and skim milk readings.

C is the "Stone type" lactometer with the short range of specific gravity scale.

D is the Thermometer arrangement showing pencil clip that holds thermometer to jar.

FIG. I

yielded only three that were accurate enough to use with a certain feeling of confidence; the other fifteen varied from 0.3 to 1.5 degrees at 60° F.

An instrument was purchased of a type from which we selected by gravimetric determinations an accurate "standard" lactometer to use routinely as the control against which we checked many lactometers obtained in the local

market and from other laboratories. This was the United States Department of Agriculture lactodensimeter. It has a range from 24 to 37 Quevenne degrees distributed over a scale of $3\frac{1}{4}$ inch length. Each degree is divided into 1/10's. Thus, each degree is approximately $\frac{1}{4}$ inch in height and the variation by the reading at the surface of the liquid, or at the top of the

meniscus, by such length scale minimized the inaccuracies of a shorter scale instrument. However, in the control of market milk the actual specific gravity scale in which we are interested includes those just above and just below the perfect scoring and the illegal product. Our main objection to this lactodensimeter is that its size necessitates a large hydrometer jar and a considerable amount of milk to facilitate reading. Furthermore, the bulk of the instrument introduces a factor of delay while waiting for the temperature of the instrument and the temperature of the liquid to become the same.

Late in 1928 an attempt was made by us to interest manufacturers of laboratory precision instruments in a special lactometer designed particularly for routine health department control work. In May, 1929, Hiergesell Bros., of Philadelphia, Pa., submitted a blueprint which incorporated the requirements we had made as being desirable.

The range in Quevenne degrees was reduced to 29–35 degrees. Thus 22 Quevenne degrees were eliminated from the older type of scale. The thermometer was discarded as a part of the instrument, since it was our firm belief that accuracy in but one thing was more possible of attainment than if other factors were introduced into the in-

strument's construction. This, commercially, has become known throughout the State of California as the "Dr. Stone type" and has been introduced through its own merits as the recommended State lactometer. Coincident with its use, the variations on the same milk in different laboratories practically ceased.

The thermometer used is a "cloud and pour" $4\frac{1}{4}$ inch immersion, with a range of 36° to 120° F. in two-degree divisions. The total length is $8\frac{3}{4}$ inches and is designed according to the ASTM specifications. It is fastened to the ungraduated cylinder (used instead of a hydrometer jar) by means of an ordinary pencil clip. This fixing of the thermometer to the jar permits of ready pouring of milk samples in and out without disturbing the thermometer. Thermometer, clip and jar are shown in Figure I at the righthand side of the picture. The cylinder used is a lipped, ungraduated cylinder and is $1\frac{5}{8}$ inches outside diameter and is $8\frac{1}{4}$ inches high. A half-pint milk sample can be tested using this style thermometer and the Stone Lactometer. At present but one manufacturer has coöperated in the making of this instrument but there is nothing to prevent other manufacturers from making it as there are no royalties or patents involved with this design.

Marriage Premiums in Italy

THE National Bureau of Maternal and Child Welfare of Italy has recently begun to give premiums to mothers of illegitimate children who later marry, at the time of their marriage. At the beginning of the present year this policy was extended to all young women intending to marry, and 2,000,000 lire was appropriated for that purpose.

Each premium is to amount to about 200 lire. A list is to be kept of the women receiving these premiums, and during pregnancy and after the birth of a child they will be asked to take advantage of the health centers, day nurseries, free lunch rooms, and other welfare arrangements maintained by the Bureau.—*Maternita ed Infanzia*, Rome, Mar., 1933.

THE DEPRESSION AND HEALTH

THE effects of the depression on public health have been discussed from various aspects. In our August number we carried a paper in which evidence which had been subjected to careful scrutiny was brought forward by one clinic to show that malnutrition is showing some effects. Those who have lived in the drought section, which was affected by floods only a few years ago, have had some first-hand experience and have been somewhat doubtful as to the evidences of malnutrition due to the depression since many of the cases in which malnutrition undoubtedly existed were proved to have preceded the drought. Indeed, many health officers have remarked on the unusual good health throughout the country and the marked absence of bad effects attributable to the depression. All, however, have been uneasy over the situation and feel confident in predicting that bad effects of greater or less severity will be seen sooner or later. However, we must be grateful that the results are no worse than are so far evident.

In many states of the Union, boards of health have had their budgets cut, in some cases to an alarming extent. Personnel has been reduced and certain activities discontinued. One of the most serious things which have happened to public health is the curtailment of funds for the U. S. Public Health Service. When the drought hit hardest, the government was in a position to appropriate money to be apportioned by the Service in aiding the affected states for one year. Then a bill was brought in which passed through the Senate without a dissenting vote, increasing by three times the amount for assistance, and extending the aid to every state in the Union which needed it. Some thought that this provision would insure its passage. Nevertheless, the bill was killed, and assistance for the drought areas by our government ceased.

Recently we have had a report from the Surgeon General of the Public Health Service which tells of the cuts which will be in effect for the fiscal year beginning July 1, 1933. The total amount allowed by the Bureau of the Budget is \$7,860,000, although \$10,380,328 was appropriated by Congress. This means, of course, extensive curtailment of activities, although every effort is being made to keep those which are essential in motion. The salaries of all officers have been cut 15 per cent. Further savings have been effected by retiring a number of commissioned medical officers, some of whom are well known to the profession of the United States and Europe, and whose services can ill be spared. The marine hospitals and field relief stations have been cut to \$4,420,000 from \$5,600,000. In some quarters there has been a feeling that sick people will be taken care of, regardless of government help. Aid for county health units in 28 states which have been assisted by the Public Health Service will be cut off, and there is little doubt that many of these will be abandoned, though it is hoped that the states and counties will continue as many of them as possible.

The quarantine and immigration services in foreign ports have been greatly reduced, some 10 American physicians having been discharged; others, together with 700 acting assistant surgeons on part-time service, have suffered reductions in salaries.

What many will feel as a peculiar injury is the reduction by some 50 per cent of funds for scientific research. This will come at a time when the new buildings of the National Institute of Health, in which we might well hope for an increase of research, are nearing completion. The list of employees dropped is large; 13 from the Washington office, 650 from field stations, and 310 from rural sanitation. Some 1,500 others will be required to take 5 days vacation each month without pay.

All the readers of this *Journal* recognize what President Cleveland once said—that we are confronted by a condition and not a theory—yet we believe that cutting appropriations for health work is the poorest sort of economy. Health is wealth, and no nation has ever been great and maintained its greatness on a feeble population. Doubtless some economies can be made without injury to the protection afforded by the Public Health Service and the National Institute of Health, but we must still hope for expansion, rather than contraction, and entirely apart from how it may affect individuals, all anxiously look forward to the day when liberal funds will again be supplied and full activities be resumed. All of our members and readers should urge this point of view, and do all they can to keep appropriations for public health purposes at the highest possible level.

MALARIAL FEVER

ONE of the distinctive services rendered to the world by the Health Organization of the League of Nations has been its outstanding studies on malaria. Presumably even to those who live in malarial countries and know something of its ravages, the reports made by the League of Nations since its Commission was established in 1923 have been astonishing. Three major reports have been issued, the last one before the present showing the requirements for quinine in malarial countries and the prevalence of the disease. The use of quinine increased threefold from about 1880 to 1911, and the price has also increased threefold since

1892. The annual purchase of quinine was estimated at some 12 million dollars, though it is common knowledge in every country that a large portion of those infected with malaria do not receive specific treatment.

The last report treats of the therapeutics of malaria. Since there is no disease in which the sterilization of cases is more important as a matter of prevention than malaria, this report is of great interest from the prophylactic standpoint. There are several apparent contradictions in the behavior of malaria which render treatment and sterilization difficult. When the mosquito cycle of the malarial parasite was demonstrated, some believed that the disease could be overcome by making a break in the epidemiological chain by the use of quinine to destroy the parasite in the human host. Others believed that the destruction of the carrier mosquito, as well as of breeding places, offered the best success. It can now be said, on the evidence of extensive field experiments, that quinine has always failed as a mass preventive, and though we know it cures developed attacks, it does not always prevent either man or the mosquito from becoming infected.

One of the great problems of the Commission was to answer questions as to the prevention of infection, the prevention of relapses, and the determination of a mass treatment which would destroy gametocytes and thus prevent infection of mosquitoes. They state categorically that no drug is known, which, taken in doses which are not injurious during the infection, will effectively destroy the sporozoites of malaria before they are able to continue their life cycle in the human host. There is no drug nor any combination of drugs which will positively kill all parasites in the human host, and certainly prevent relapse.

The Commission further disapproves of attempts to bring about sterilization of all parasites during first attacks, and recognizes that nature provides a defensive mechanism which in the course of time produces immunity. Where sterilization is complete, this immunity is not developed. The frequency as well as the severity of relapses depends largely on the defensive powers of the infected person, and though this may be natural in some cases, it is also acquired. Consequently, the infected person should be allowed to develop this acquired immunity as well as the defensive power, if possible. If treated by large and continuous doses of specific drugs, they do not have an opportunity of developing defense, and experience has shown that, as a rule, such persons relapse every month over a long period. For this reason no attempt is made to prescribe a treatment for the prevention of relapses during the primary attack, and use of the specific drug at a later period and more sparingly during later recrudescences is advised. This applies particularly to benign tertian and quartan types of fever. For malignant tertian (*Aestivo autumnal*) it is considered justifiable to sterilize by specific drugs during the first recrudescence. In conditions in which it is not considered justifiable positively to prevent relapses, a system of clinical prophylaxis, which consists of giving 6 grains of quinine daily throughout a period of residence in a malarial country, and for some months after, is advocated. This does not completely eradicate the infection, so the defensive mechanism of the body is allowed to work and become increasingly powerful; it reduces the number of gametocyte carriers and their capacity for infecting mosquitoes, and at the same time enables agricultural and other workers to pursue their tasks.

Gametocytes are produced in greater numbers in primary attacks and early recrudescences than later, so that in highly endemic areas, little could be accomplished in preventing transmission of malaria without treatment of infants and children. It seems that in such areas adults seldom carry a sufficient number

of gametocytes to insure the infection of mosquitoes, and this is probably one of the reasons why mass treatment usually gives poor results.

The Commission repeatedly asserts that treatment with quinine can never be regarded as a *therapia sterilisans magna*. Knowledge of malaria now seems to be advancing after standing practically still for a number of years. This is attributed to the study of the biological aspects of the subject, while the discovery of effective synthetic antimalarial remedies has led to many experiments and to a promise of improvements in the treatment of the disease. A clear, and we believe useful, practical distinction is drawn between sporozoite therapy, which is called true causal prophylaxis, and clinical prophylaxis. For the first, it is the opinion that no drug is known which in harmless doses can be considered certainly effective. For the second, quinine is the most effective and best drug known, and daily doses of 6 grains are advised.

As far as the prevention of spread goes—and in this we are particularly interested—quinine and atabrin are effective in benign tertian and quartan, but against the gametocytes of malignant tertian (*Aestivo autumnal*) these drugs have only a feeble action. Plasmoquine has a powerful action against them, and it is recommended that it be given twice a week during the time when crescents are present in the peripheral blood. In badly infected areas (in Lagos, 90 per cent of the young children and 50 per cent of adults harbor malignant tertian parasites in their blood, and neighboring rural districts in all probability practically the entire population over 1 year of age, some 120,000 persons, carry malarial parasites in their blood continuously) it may become possible to substitute for present schemes of mass treatment a rational plan which will stop malaria from being fatal and mitigate its severity without interfering with the process leading to acquired immunity, which the Commission believes is most important to adult populations. In 1927, the Commission advised countries in which malaria was extremely prevalent to content themselves with the organization of their public health service on these principles, rather than to undertake such radical measures as are necessary for the complete elimination of the parasites.

NONSPECIFIC IMMUNITY BY HETEROLOGOUS VACCINATION

IMMUNITY is one of the most interesting as well as most important reactions of which we have any knowledge. Almost from time immemorial, it has been known that one attack of most contagious diseases protected from a second, generally throughout life. The first to theorize rationally on the subject and propose explanations of immunity was Pasteur, who discovered the first bacterial vaccine, when he found that attenuated cultures of the chicken cholera organism would protect against virulent ones. From that time on, experiments have been brought forward with confusing rapidity, and while we can say certainly that we know a good deal about immunity in general, and certain types of immunity in particular, there are still many points which remain to be clarified.

A recent piece of work is of more than usual importance. Armstrong and Harrison¹ have carried out experiments on a large number of animals immunized

against tetanus and botulinus, vaccine virus, and antityphoid vaccine, using normal saline injections as controls. After a proper period, these animals were injected with known fatal doses of diphtheria toxin-antitoxin, poliomyelitis virus, and cultures of *B. prodigiosus*. The general conclusion is that the various substances against which the animals were immunized exercised a subsequent protective action against the infectious and toxic agents used. The authors believe that this increased resistance is due to a "mobilization, strengthening and training of the defense mechanism." They recognize that increased resistance produced through heterologous immunization is only relative, and is not very strong, though they believe that the evidence indicates that it may be of value in modifying the course of such subsequent infections as poliomyelitis and post-vaccinal encephalitis, as well as in increasing resistance to various subsequent infections.

In a review of the literature, it is pointed out that as early as 1893, Klein found that intraperitoneal injections of several varieties of bacteria would render guinea pigs refractory to known fatal doses of the same or other germs given from 8 to 12 hours later by the same route. These experiments have been confirmed by a number of observers, and some have even shown that preliminary intraperitoneal injections of various substances—bouillon, peptone, urine, etc.—would give a certain degree of immunity. In a few instances, the immunity against certain bacteria such as *B. cholerae*, was quite marked. The experiments cited include injections with yeast and with virulent tubercle bacilli, the latter of which were said to have rendered guinea pigs refractory to a certain extent against virulent anthrax. Vaccination against tuberculosis on a large scale, as carried out by Calmette with BCG, indicates that this nonspecific immunity notably reduces the general mortality of infants.

The increased protection by heterologous vaccines has been attributed to a cross-immunity, which is assumed and does not appear ever to have been proved. Armstrong and Harrison discredit this explanation on account of the great variety of substances which have been found capable of inducing increased resistance, and also the failure to find antibodies in the serum which show any cross-protection. They discuss also the fact noted in various camps during the World War, that recruits from rural areas were much more subject to infectious diseases than those who came from cities. An unusually striking instance of this was observed among two groups of Missouri recruits. The explanation in the majority of these cases seems clearly to be that urban dwellers are much more exposed to the ordinary so-called infectious diseases of childhood, but the point has been made by Love and Davenport that this would hardly account for the lowering in the incidence of such diseases as lobar pneumonia and cerebrospinal meningitis.

Long ago, Metchnikoff attributed such increased resistance to the breaking up of the phagocytes (phagolysis) and the setting free of cytase, at least as far as those cases in which some immunity is induced by intraperitoneal injections of bouillon. The general fact remains that as we grow older, we are apt to become less susceptible to certain infectious diseases, and this has been variously attributed to mild and unrecognized attacks or to vaccination by small, non-clinical, disease-producing infections. The whole matter is of extreme interest and importance, to which the contribution referred to has added valuable material.

Letter to the Editor

To the Editor:

I desire to caution rural health officers in placing blind confidence or reliance in the immunization results obtained and reported by Dr. William H. Park in his article in the June issue of the *Journal*, following the use of toxoid.

Dr. Park states that two doses of Ramon toxoid of from 5 to 10 flocculation units per c.c. will immunize 90 to 98 per cent of young children who receive it and a slightly smaller per centage of older children.

These excellent results may be expected in a city of the size of New York with its great aggregation of people, but not in rural sections. We must realize thoroughly the effect aggregation and other factors have on the whole diphtheria situation in coming to any conclusions on results obtained.

Doull has shown that 72 per cent of New York City children in the 10-14 age group were previously Schick negative. In Worcester County, Maryland, a rural county, we have found as the result of 1,050 previous Schick tests, that only 21 per cent of this specific age group were Schick negative. As negative previous Schick tests depend upon children possessing enough autogenous antitoxin, obtained by natural processes, to neutralize the toxin in the Schick, it is safe to assume that each individual child in the positive group in New York had a larger quantity of this antitoxin than the 79 per cent who were positive in Worcester County. It therefore follows that it is necessary for toxoid to stimulate a greater amount of antitoxin in each child in Worcester County, Maryland, or in any other rural com-

munity, to render it Schick negative.

A series of 1,208 Schick tests have just been completed in the above named rural community, one year after each child in the series had received two doses of the Ramon toxoid of 5 to 10 flocculation units per c.c. Only 69 per cent of the white children in this group were rendered Schick negative.

The writer predicts that as the evidence is collected, as to the lack of response of rural children to the Ramon toxoid, either the antigenic content of this type toxoid will have to be increased or the Ramon toxoid will be completely replaced by the Havens' type alum-precipitated toxoid.

A series of 100 colored children were given a 1 c.c. dose of the Havens' toxoid, all of whom were previously Schick positive. Six to seven weeks later, Schick tests were done on 93 of these children and 92 or 98.8 per cent were found Schick negative.

It should be noted that control tests were done on all the children mentioned to eliminate the pseudo-positive reaction.

If rural health officers all over the country rely implicitly on Dr. Park's results and eliminate the subsequent Schick test to check the results obtained in each locality, unfortunate occurrences will develop in the future which will shake the public's confidence in diphtheria immunization.

I shall be glad to submit in detail the results of the diphtheria immunization work carried on in a strictly rural county at the next annual meeting.

BRADFORD MASSEY, M.D.,
Deputy State Health Officer.

Pocomoke City, Md.,
June 27, 1933.

PRELIMINARY PROGRAM OF THE SIXTY-SECOND
ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION

INDIANAPOLIS, IND., OCTOBER 9-12, 1933

THE Annual Meeting Program Committee presents the preliminary program of the scientific sessions of the Sixty-second Annual Meeting of the American Public Health Association and information concerning meetings of related organizations.

The program of the Institute on Health Education to be held October 7, 8 and 9 will be found on pages 968 and 969.

Since the following program cannot be considered definite in every respect now, delegates are urged to consult the Final Program, available at the Registration Desk in the Claypool Hotel at the time of the meeting. All meetings, unless otherwise stated, will be held in the Claypool Hotel.

Monday, 9:30 A.M.

HEALTH OFFICERS

First Session—Travertine Room, Lincoln Hotel

An Unusual Outbreak of Para-Typhoid A. JOSEPH P. FRANKLIN, M.D., Health Officer, Allegany County, Cumberland, Md.

Heart Disease. LOUIS I. DUBLIN, PH.D., Third Vice-President and Statistician, and DONALD B. ARMSTRONG, M.D., Third Vice-President, Metropolitan Life Insurance Company, New York, N. Y.

Responsibility for the Health Program. MORRIS FISHBEIN, M.D., Editor, *Journal of the American Medical Association*, Chicago, Ill.

Discussion. CHARLES F. WILINSKY, M.D., Deputy Commissioner, Child Hygiene Division, Department of Health, Boston, Mass., and MATTHIAS NICOLL, JR., M.D., Commissioner of Health, Westchester County, White Plains, N. Y.

Section Business.

VITAL STATISTICS

First Session—Empire Room

Section Business. Appointment of Nominating Committee.

The Work and Plans of the Section Council. J. V. DEPORTE, PH.D., *Chairman* of the Section, Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Monday, 9:30 A.M.

VITAL STATISTICS (Cont.)

First Session—Empire Room

Prospects for Completing the Registration Area (Report of the Committee). *Chairman*, T. F. MURPHY, M.D., Chief Statistician for Vital Statistics, Bureau of the Census, Washington, D. C.

Collection of Accident Statistics (Report of the Committee). *Chairman*, W. THURBER FALES, Sc.D., State Registrar, State Board of Health, Montgomery, Ala.
Discussion. R. L. FORNEY, National Safety Council, Chicago, Ill.

Should Birth and Death Certificates Be More Specific as to Residence for Purposes of Allocation? (Report of the Committee). *Chairman*, A. W. HEDRICH, Sc.D., Associate in Biostatistics, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Report of the Committee on Registration of Births of Illegitimate and Adopted Children. *Chairman*, SHELDON L. HOWARD, State Registrar, State Department of Public Health, Springfield, Ill.

Discussion. W. J. V. DEACON, M.D., State Department of Health, Lansing, Mich.

Procedure as to Filing Deferred Certificates (Report of the Committee). *Chairman*, STEWART G. THOMPSON, D.P.H., Director, Division of Vital Statistics, State Board of Health, Jacksonville, Fla.

Classification of Stillbirths (Progress Report of the Committee on Accuracy of Certified Causes of Death). *Chairman*, HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

EPIDEMIOLOGY

First Session—Assembly Room

Outbreak of an Erysipeloid Condition Among the Workers in a Bone Button Factory Due to the Bacillus of Swine Erysipelas. G. FOARD MCGINNES, M.D., Director of Laboratories, and FORREST SPINDLE, State Department of Health, Richmond, Va.

Diphtheria Studies: I. The Significance of the Schick Test in the Adult. C. C. YOUNG, D.P.H., Director; W. E. BUNNEY, Ph.D., Associate Director; GEORGE D. CUMMINGS, Bacteriologist; MINNA CROOKS; and FILIP C. FORSBECK, M.D., Epidemiologist; State Department of Health Laboratories, Lansing, Mich.

Measles Epidemic in Albany, New York, in 1926-1927. EDWARD S. GODFREY, JR., M.D., Director, Local Health Administration, State Department of Health, Albany, N. Y. (*Stereopticon Illustration*.)

The Epidemiology of Lobar Pneumonia. WILSON G. SMILLIE, M.D., Professor of Public Health Administration, Harvard University School of Public Health, Boston, Mass., and FREDERICK S. LEEDER, M.D., Medical Director, Southern Berkshire Health District, Brookline, Mass. (*Stereopticon Illustration*.)

Rocky Mountain Spotted Fever: Observations on Epidemiology with Particular Reference to the Western United States. R. R. PARKER, Ph.D., In Charge, Rocky Mountain Spotted Fever Investigations, U. S. Public Health Service, Hamilton, Mont. (*Stereopticon Illustration*.)

Section Business.

Monday, 9:30 A.M.

INDUSTRIAL HYGIENE

First Session—Club Room

Industrial Intoxication Following Skin Sorption. CAREY P. MCCORD, M.D., Chairman of the Section, and Medical Director, Industrial Health Conservancy Laboratories, Cincinnati, O.

X-Ray Findings in So-Called Acute Silicosis. HOMER L. SAMPSON, Director, Trudeau Sanatorium, Trudeau, N. Y.

The Pathological Lesions in So-Called Acute Silicosis. LEROY U. GARDNER, M.D., Director, Saranac Laboratory for the Study of Tuberculosis, Saranac Lake, N. Y.

The Silica Content of the Lungs of a Group of Tunnel Workers. CLAYTON S. SMITH, PH.D., and HELEN L. WIKOFF, PH.D., Laboratory of Physiological Chemistry and Pharmacology, Ohio State University, Columbus, O.

Section Business.

CHILD HYGIENE AND PUBLIC HEALTH NURSING SECTIONS AND THE AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Joint Session—Riley Room

SCHOOL HEALTH PROGRAMS

Scarlet Fever Immunization. O. B. NESBIT, M.D., Board of Education, Gary, Ind.

Discussion. GEORGE H. RAMSEY, M.D., Director, Division of Communicable Diseases, State Department of Health, Albany, N. Y.

Educator's Viewpoint. DELBERT OBERTEUFFER, PH.D., Ohio State University, Columbus, O.

Discussion.

Medical Viewpoint. GEORGE B. DARLING, DR.P.H., W. K. Kellogg Foundation, Battle Creek, Mich.

Discussion.

Nurse's Viewpoint. NELLIE PALMER, R.N., Bureau of Nursing, Board of Education, Des Moines, Ia.

Discussion.

Conducted Tour of the Exhibits.

Monday, 12:30 P.M.

PUBLIC HEALTH NURSING

Luncheon Session—Chateau Room

Section Business.

Monday, 2:30 P.M.

HEALTH OFFICERS

Second Session—Riley Room

MODERN TRENDS IN PUBLIC HEALTH ADMINISTRATION

State Health Work. E. L. BISHOP, M.D., State Commissioner of Public Health, Nashville, Tenn.

City Health Work. JOHN P. KOEHLER, M.D., Commissioner of Health, Milwaukee, Wis.

County Health Work. JOSEPH W. MOUNTIN, M.D., Surgeon, U. S. Public Health Service, Washington, D. C.

LABORATORY

First Session—Assembly Room

Presiding: ANNA W. WILLIAMS, M.D., *Chairman*, Laboratory Section.

Address. ANNA W. WILLIAMS, M.D., Bureau of Laboratories, Department of Health, New York, N. Y.

Report of the Committee on Standard Methods. *Chairman*, AUGUSTUS B. WADSWORTH, M.D., Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Laboratory Problems in Milk Pasteurization (Preliminary Report of the Committee on Milk Pasteurization Studies). *Chairman*, ROBERT S. BREED, Ph.D., New York State Agricultural Experiment Station, Geneva, N. Y.

Report of the Committee on Water Pollution Studies. *Chairman*, JAMES A. NEWLANDS, Henry Souther Engineering Company, Hartford, Conn.

Report of the Committee on Bathing Places. *Chairman*, W. D. STOVALL, M.D., State Laboratory of Hygiene, Madison, Wis.

SYMPOSIUM ON THE CONTROL OF FOOD HANDLERS AND THE DETECTION OF CARRIERS AMONG THEM

Detection by Laboratory Methods of Disease Carriers Among Food and Drink Handlers. RALPH EMERSON DUNCAN, M.D., Department of Health, Kansas City, Mo.

Control of Food Poisoning with Reference to the Medical and Laboratory Examination of Food Handlers. JACQUES P. GRAY, M.D., Department of Public Health, San Francisco, Calif.

The Feasibility of Attempting to Control Enteric Disease by the Examination of Specimens from Food Handlers. RUTH GILBERT, M.D., and MARION B. COLEMAN, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Value of Duodenal Aspiration in Diagnosis of Chronic Fecal Typhoid Carriers. LLOYD ARNOLD, M.D., and LARS GULBRANDSEN, Department of Bacteriology and Preventive Medicine, University of Illinois, College of Medicine, Chicago, Ill.

Monday, 2:30 P.M.

FOOD AND NUTRITION

First Session—Lincoln Room, Lincoln Hotel

Nutrition in the Public Health Program. LYDIA J. ROBERTS, PH.D., Chairman, Department of Home Economics, University of Chicago, Chicago, Ill.

Nutrition and Family Food Budgets. LUCY GILLET, Association for Improving the Condition of the Poor, New York, N. Y.

Pellagra. W. H. SEBRELL, National Institute of Health, Washington, D. C.

Dietary Investigations Bearing on Pellagra. MARGARET R. SANDELS, PH.D., Educator, Teaching and Investigations in Nutrition, Florida State College for Women, Tallahassee, Fla.

Theory of the Etiology of Pellagra. J. C. NORRIS, M.D., Associate Professor of Pathology and Public Health, Emory University, Atlanta, Ga.

Vitamin G Deficiency. PAUL R. DAY, M.D., School of Medicine, University of Arkansas, Little Rock, Ark.

Report of the Committee on Nutrition. *Chairman,* PROFESSOR HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

PUBLIC HEALTH ENGINEERING SECTION AND CONFERENCE OF STATE SANITARY ENGINEERS

Joint Session—Palm Room

Presiding: L. F. WARRICK, *Chairman,* Conference of State Sanitary Engineers.

When Are Milk Containers and Equipment Clean and Sterile? (Report of the Committee on Milk Supplies). *Chairman,* C. A. HOLMQUIST, Director, Division of Sanitation, State Department of Health, Albany, N. Y.

Report of the Joint Committee on Rural Sanitation. *Chairman,* H. E. MILLER, Special Expert, U. S. Public Health Service, Norfolk, Va.

The Sanitary Works of Indianapolis. C. K. CALVERT, Sanitary District of Indianapolis, Indianapolis, Ind.

Discussion. L. A. GEUPEL, Chief Engineer, Department of Sanitary Engineering, State Board of Health, Indianapolis, Ind.

Present Status of the Program of the Tri-State Treaty Commission on Abatement of Pollution of Harbor and Coastal Waters within the (N. Y.) Metropolitan Area. F. S. TAINTER, Engineer, New York, N. Y.

Discussion. C. A. HOLMQUIST, Director, Division of Sanitation, State Department of Health, Albany, N. Y.

Monday, 6:30 P.M.

PUBLIC HEALTH EDUCATION

Dinner Session—Louis XV Parlor

Closed Session—for Fellows and Members of the Section only

Section Business.

Monday, 8:00 P.M.

FIRST GENERAL SESSION

Riley Room

Invocation.

Address of Welcome. WILLIAM F. KING, M.D., Chairman of the Local Committee, Indianapolis, Ind.

Address of the President of the American Public Health Association. America's Contributions and Problems in Public Health. JOHN A. FERRELL, M.D., Associate Director, International Health Division, The Rockefeller Foundation, New York, N. Y.

Announcement of Awards.

Reception and Dancing.

Tuesday, 9:30 A.M.

INDUSTRIAL HYGIENE

Second Session—Club Room

Poisoning by Petroleum Distillates—Case Reports. EMERY R. HAYTHURST, M.D., PH.D., Consulting Industrial Hygienist, Columbus, O.

Treatment of Cyanide Poisoning. K. K. CHEN, PH.D., CHARLES L. ROSE and G. H. A. CLOWES, PH.D., Lilly Research Laboratories, Indianapolis, Ind.

Dermatitis in the Oil Refining Industry. LOUIS SCHWARTZ, M.D., U. S. Public Health Service, New York, N. Y.

Visual Disturbances Due to Carbon Tetrachloride—Case Reports. ZOLTON T. WIRTSCHAFTER, M.D., Medical Consultant, State Federation of Labor, Cleveland, O.

Conducted Tour of the Exhibits.

PUBLIC HEALTH EDUCATION

First Session—Lincoln Room, Lincoln Hotel

THE ORGANIZATION OF ADULT GROUPS FOR HEALTH EDUCATION

In Cities. MARY P. CONNOLLY, Director, Division of Health Education, Department of Health, Detroit, Mich.

In Rural Districts. W. W. PATTY, M.D., Director, Physical Welfare Training Department, Indiana University, Indianapolis, Ind.

PUBLIC HEALTH ENGINEERING

First Session—Palm Room

SYMPOSIUM ON PUBLIC HEALTH ENGINEERING PROBLEMS OF LARGE COMMUNITIES

The Growth of American Cities. HOWARD W. GREEN, Secretary, Cleveland Health Council, Cleveland, O.

Keeping Up with the Demand for Adequate Pure Water. HARRY E. JORDAN, Filtration Engineer, Indianapolis Water Company, Indianapolis, Ind.

Tuesday, 9:30 A.M.

PUBLIC HEALTH ENGINEERING (Cont.)

First Session—Palm Room

Liquid Wastes: Their Treatment and Disposal. LANGDON PEARSE, Sanitary Engineer, Sanitary District of Chicago, Chicago, Ill.

Practical Application of Milk Control. J. R. JENNINGS, Chief, Milk Control Division, Department of Public Health, Louisville, Ky.

Can Refuse Collection and Disposal Systems Be Improved? H. P. EDDY, JR., Metcalf and Eddy, Boston, Mass.

The Air We Breathe and the Sounds We Hear. JOEL I. CONNOLLY, Board of Health, Chicago, Ill.

Mosquitoes Have No Place in a City. RALPH E. TARBETT, Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

Section Business.

HEALTH OFFICERS, LABORATORY AND EPIDEMIOLOGY SECTIONS

Joint Session—Assembly Room

SYMPOSIUM: WHAT ARE THE ESSENTIALS OF TYPHOID FEVER CONTROL TODAY?

Presiding: ROBERT H. RILEY, M.D., *Chairman*, Health Officers Section; WADE H. FROST, M.D., *Chairman*, Epidemiology Section; and RUTH GILBERT, M.D., representing the Laboratory Section.

*For the Epidemiology Section—*GEORGE H. RAMSEY, M.D., Director, Division of Communicable Diseases, State Department of Health, Albany, N. Y.

*For the Health Officers Section—*A. J. CHESLEY, M.D., Executive Officer, State Board of Health, St. Paul, Minn.

*For the Laboratory Section—*E. O. JORDAN, PH.D., Department of Hygiene and Bacteriology, University of Chicago, Chicago, Ill.

Discussion. WILLIAM H. PARK, M.D., Director, Bureau of Laboratories, Department of Health, New York, N. Y.; D. F. MILAM, M.D., Epidemiologist, State Department of Health, Raleigh, N. C.; and L. L. LUMSDEN, M.D., U. S. Public Health Service, New Orleans, La.

Conducted Tour of the Exhibits.

CHILD HYGIENE

First Session—Travertine Room, Lincoln Hotel

(Special invitation extended to members of the American Association of School Physicians)

NEW AND INTERESTING DEVELOPMENTS IN THE CHILD HEALTH FIELD
Health Education in the Virgin Islands. SALLY LUCAS JEAN, Health Consultant, New York, N. Y.

Discussion. PAULINE BROOKS WILLIAMSON, Chief, School Health Bureau, Welfare Division, Metropolitan Life Insurance Company, New York, N. Y.

Tuesday, 9:30 A.M.

CHILD HYGIENE (Cont.)

First Session—Travertine Room, Lincoln Hotel

Some Public Health Aspects of Maternal Mortality. FRANCES C. ROTHERT, M.D., Associate Medical Officer, U. S. Children's Bureau, Washington, D. C.

Coördination of Nursery School and Public Health Nursing Service. GENEVA F. HOILJEN, R.N., Director, Albany Guild for Public Health Nursing, Albany, N. Y.

Discussion. HUNTINGTON WILLIAMS, M.D., Commissioner of Health, Baltimore, Md.

Motivating Teacher Participation in New Type Health Activity. RUTH HEAVENRIDGE, Teacher-Director, Special Classes for Indianapolis Public Schools, Indianapolis, Ind.

Discussion. AMELIA T. WOOD, Director, Health Service, Ball State Teachers' College, Muncie, Ind.

Tuesday, 12:30 P.M.

INDUSTRIAL HYGIENE

Luncheon Session—Chateau Room

Report of the Committee on Standard Practices in the Problem of Compensation of Occupational Diseases. *Chairman,* HENRY H. KESSLER, M.D., State Department of Labor, Newark, N. J.

Report of the Committee on Pneumoconiosis. *Chairman,* R. R. SAYERS, M.D., U. S. Bureau of Mines, Washington, D. C.

Tuesday, 2:30 P.M.

PUBLIC HEALTH NURSING

First Session—Assembly Room

THE CONTRIBUTION OF PUBLIC HEALTH NURSING TO VARIOUS PHASES OF THE PUBLIC HEALTH PROGRAM

To Communicable Disease Control. MARGUERITE A. WALES, R.N., General Director of Nurses, Henry Street Settlement Visiting Nurse Service, New York, N. Y.

Discussion. LOUISE KUCK TOOKER, R.N., Superintendent of Nurses, Department of Health, Cincinnati, O.

To the School Age Group. MARION G. RANDALL, R.N., Division of Research, Milbank Memorial Fund, New York, N. Y.

To the Maternity, Infancy and Preschool Age Group. AGNES G. TALCOTT, R.N., Director of Nurses, Department of Health, Los Angeles, Calif.

How to Make Public Health Nursing Fit into a Budget. ALMA C. HAUPT, R.N., Associate Director, National Organization for Public Health Nursing, New York, N. Y.

Tuesday, 2:30 P.M.

PUBLIC HEALTH ENGINEERING

Second Session—Palm Room

Effect of Economic Conditions on Public Health Engineering Work.
MALCOLM PIRNIE, Civil Engineer, New York, N. Y.

Discussion.

A View of Environmental Sanitation in the Control of Communicable Diseases.
WADE H. FROST, M.D., School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Discussion. ARTHUR E. GORMAN, Engineer of Water Purification, Department of Public Works, Chicago, Ill.

Some Factors Involved in the Use of Chloramines for the Disinfection of Swimming Pool Waters. A. H. FLETCHER, Director, Bureau of Sanitation, Department of Health, Memphis, Tenn., and E. C. LINK, Director, Bureau of Laboratories, State Department of Health, Nashville, Tenn.

A Hypochlorite Feeding Device. F. R. SHAW, Sanitary Engineer, U. S. Public Health Service, Chicago, Ill.

VITAL STATISTICS

Second Session—Club Room

Has Diabetes Become More Prevalent? CHARLES BOLDUAN, M.D., Director of Health Education, Department of Health, New York, N. Y.

Death Rates from Puerperal Septicemia in Large Cities, 1922 to 1929.
GARUS B. HARMON, M.D., Associate Professor of Hygiene, School of Medicine, Western Reserve University, Cleveland, O.

DISCUSSION OF REGISTRATION PROBLEMS

Adjustment of Vital Statistics Divisions to Depression Budgets.

Discussion opened by: W. THURBER FALES, Sc.D., State Registrar, State Board of Health, Montgomery, Ala., and CARL E. BUCK, DR.P.H., Field Director, American Public Health Association, New York, N. Y.

Section Business. Election of Officers.

PUBLIC HEALTH EDUCATION

Second Session—Lincoln Room, Lincoln Hotel

RETAILING HEALTH INFORMATION AND IDEAS

Campaign Plans for Thorough Coverage of a Given City.

A Plan to Increase Understanding of the Value of Scientific Medicine.
T. J. EDMONDS, Executive Secretary, Iowa Tuberculosis Association, Des Moines, Ia.

Reaching the Negro Community. M. O. BOUSFIELD, M.D., First Vice-President and Medical Director, Supreme Liberty Life Insurance Company, Chicago, Ill.

Outline for a Social Hygiene Educational Campaign. MARGARET WELLS WOOD, American Social Hygiene Association, New York, N. Y.

Discussion.

Tuesday, 2:30 P.M.

LABORATORY AND FOOD AND NUTRITION SECTIONS

Joint Session—Riley Room

SYMPOSIUM ON MICROBIOLOGICAL EXAMINATION OF FOOD PRODUCTS

Presiding: CARL R. FELLERS, PH.D., *Chairman*, Food and Nutrition Section, and ROBERT S. BREED, PH.D., *Vice-Chairman*, Laboratory Section.

Need for Uniform Practices in the Microbiological Examination of Food Products. LAWRENCE H. JAMES, PH.D., Food Research Division, U. S. Bureau of Chemistry and Soils, Department of Agriculture, Washington, D. C.

Factors Involved in the Microbiological Examination of Canned Foods. E. J. CAMERON, PH.D., Bacteriologist, National Canners' Association, Washington, D. C.

The Examination of Fermented Foods by Laboratory Methods. CARL S. PEDERSON, PH.D., Bacteriologist, New York State Agricultural Experiment Station, Geneva, N. Y.

The Microbiological Examination of Fresh and Frozen Fruits and Vegetables. F. W. TANNER, PH.D., Department of Bacteriology, University of Illinois, Urbana, Ill.

The Need for Methods for the Bacteriological Examination of Crustacea. A. C. HUNTER, PH.D., U. S. Food and Drug Administration, Department of Agriculture, Washington, D. C.

Suggested Laboratory Procedures for Use in Determining the Cause of Food Poisonings. S. A. KOSER, PH.D., Department of Hygiene and Bacteriology, University of Chicago, Chicago, Ill.

Tuesday, 6:30 P.M.

FOOD AND NUTRITION

Dinner Session—Chateau Room

Section Business.

PUBLIC HEALTH ENGINEERING

Joint Dinner—Travertine Room, Lincoln Hotel

Public Health Engineering Section and Conference of State Sanitary Engineers. Annual Engineers' Stag Dinner Party. Toastmaster—"BILL" ORCHARD, Wallace & Tiernan Company, Newark, N. J.

Tuesday, 7:00 P.M.

PROFESSIONAL EDUCATION

Dinner Session—Riley Room

Presiding: W. S. LEATHERS, M.D., *Chairman*, Committee on Professional Education.

Policies and Objectives of the Committee on Professional Education. W. S. LEATHERS, M.D., School of Medicine, Vanderbilt University, Nashville, Tenn.

Elements Involved in Determining the Qualifications of Health Officers. E. L. BISHOP, M.D., State Commissioner of Public Health, Nashville, Tenn.

Tuesday, 7:00 P.M.

PROFESSIONAL EDUCATION (Cont.)

Dinner Session—Riley Room

Qualifications and Training of Local Health Officers. THOMAS PARRAN, JR., M.D., State Commissioner of Health, and DON M. GRISWOLD, M.D., State Department of Health, Albany, N. Y.

Discussion opened by: A. W. FREEMAN, M.D., Professor of Public Health Administration, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Wednesday, 9:30 A.M.

CHILD HYGIENE

Second Session—Travertine Room, Lincoln Hotel

(Special invitation extended to members of the American Association of School Physicians)

CHILD HEALTH DURING DEPRESSION YEARS—ECONOMIC ASPECTS

What Economies Can Be Made in Programs with Least Detriment to the Health of the Children? CARL E. BUCK, DR.P.H., Field Director, American Public Health Association, New York, N. Y.

Effect on Mental Health of Children. HENRY SCHUMACHER, M.D., Director, Child Guidance Clinic, Cleveland, O.

Effect on Physical Health of Children. MARTHA ELLIOT, Children's Bureau, Washington, D. C.

The Health and Growth of School Children During the Depression. ESTELLA F. WARNER, M.D., Surgeon, U. S. Public Health Service, Washington, D. C.

LABORATORY

Second Session—Medical Sub-Session—Chateau Room

SYMPOSIUM ON FILTERABLE VIRUSES

Presiding: ANNA W. WILLIAMS, M.D., *Chairman*, Laboratory Section.

Rabies Vaccine Protection Tests. JOHN REICHEL, V.M.D., and J. E. SCHNEIDER, Mulford Biological Laboratories, Glenolden, Pa.

Serological Studies on Vaccinia in Smallpox. RALPH S. MUCKENFUSS, Department of Bacteriology, School of Medicine, Washington University, St. Louis, Mo.

Cultivation of "Vaccine Virus" in Vitro. CHARLES R. TYLER and CAROLYN OLDENBUSCH, Department of Health Laboratories, New York, N. Y.

Purification of Vaccine Virus. MORRIS SHAEFFER, HELEN NALIBOW and ANNA GOLDBERG, New York University School of Medicine, New York, N. Y.

Wednesday, 9:30 A.M.

LABORATORY (Cont.)

Second Session—Medical Sub-Session—Chateau Room

Mechanism of Bacteriophage Lysis. J. BRONFENBRENNER, PH.D., D.P.H., Department of Bacteriology, School of Medicine, Washington University, St. Louis, Mo. (*Motion Picture Illustrations and Stereopticons.*)

The Relation of Filterable Viruses to the Pneumonias Complicating Measles, Influenza and Whooping Cough. H. A. MCCORDOCK, Department of Bacteriology, School of Medicine, Washington University, St. Louis, Mo.

Discussion of the Work on Postvaccinal Encephalitis and Tetanus. Discussion of Smallpox. CHARLES ARMSTRONG, M.D., National Institute of Health, Washington, D. C.

PUBLIC HEALTH ENGINEERING

Third Session—Palm Room

Chlorination in Sewage Disposal (Report of the Committee on Sewage Disposal). *Chairman*, LANGDON PEARSE, Sanitary Engineer, Sanitary District of Chicago, Chicago, Ill.

Report of the Committee on Fellowship and Membership. *Chairman*, LENN H. ENSLOW, Editor, *Water Works and Sewerage*, New York, N. Y.

Effect of Chemical Constituents in Water on the Human System (Report of the Committee on Water Supply). *Chairman*, J. R. BAYLIS, Physical Chemist, Department of Public Works, Chicago, Ill.

Fly Trapping. A. P. HITCHENS, Major, Medical Corps, U. S. Army, Fort Sheridan, Ill. (*Stereopticon Illustration.*)

Report of the Committee on Noise. *Chairman*, C. R. COX, Associate Sanitary Engineer, State Department of Health, Albany, N. Y. (To be read by title only.)

Report of the Committee on Promotion of Environmental Sanitation. *Chairman*, V. M. EHLERS, Chief Sanitary Engineer, State Department of Health, Austin, Tex. (To be read by title only.)

Conducted Tour of the Exhibits.

FOOD AND NUTRITION

Second Session—Club Room

The Proposed Federal Food and Drugs Act: Its Public Health Features. WALTER S. FRISBIE, Chemist, U. S. Food and Drug Administration, Department of Agriculture, Washington, D. C.

Sleep Motility as a Measure of the Effect of Different Types of Foods and Beverages on Nervousness. MELVILLE GIDDINGS, M.D., Professor of Medicine, Emory University, Atlanta, Ga.

New Mechanism of Defense Against Bacteria Through Use of Certain Foods. LLOYD ARNOLD, M.D., College of Medicine, University of Illinois, Chicago, Ill.

The Significance of Copper and Iron as Blood Restorers. C. A. ELVEHJEM, PH.D., University of Wisconsin, Madison, Wis.

Wednesday, 9:30 A.M.

FOOD AND NUTRITION (Cont.)

Second Session—Club Room

The Present Status of Vitamin Standards. E. M. NELSON, PH.D., Nutritionist, Bureau of Chemistry, U. S. Department of Agriculture, Washington, D. C.

Report of the Committee on Foods. *Chairman*, WALTER H. EDDY, PH.D., Teachers College, Columbia University, New York, N. Y.

Conducted Tour of the Exhibits.

EPIDEMIOLOGY

Second Session—Assembly Room

Tracing of Transmission of Syphilis. DUDLEY C. SMITH, M.D., and WILLIAM A. BRUMFIELD, M.D., Department of Syphilology and Dermatology, University of Virginia, Charlottesville, Va. (*Stereopticon Illustration.*)

The Epidemiological Aspects of Tuberculosis Control in Massachusetts. ALTON S. POPE, M.D., Director, Division of Tuberculosis, and GEORGE H. BIGELOW, M.D., State Commissioner of Public Health, State Department of Health, Boston, Mass. (*Stereopticon Illustration.*)

Newer Aspects in the Prevention and Control of Scarlet Fever with a Report of 60,000 Complete Immunizations. JOHN L. JONES, M.D., Epidemiologist, State Board of Health, Louisville, Ky.

The Period of Isolation for Scarlet Fever. JOHN E. GORDON, M.D., Director, Division of Epidemiology, Herman Kiefer Hospital, and GEORGE F. BADGER, Assistant to the Epidemiologist, Department of Health, Detroit, Mich. (*Stereopticon Illustration.*)

Exposure as a Factor in the Age Distribution of Measles, Diphtheria and Poliomyelitis. W. LLOYD AYCOCK, M.D., Assistant Professor, Preventive Medicine and Hygiene, Harvard Medical School, Boston, Mass.

VITAL STATISTICS AND PUBLIC HEALTH EDUCATION SECTIONS

Joint Session—Riley Room

NEWS VALUES IN HEALTH STATISTICS

Presiding: MARY SWAIN ROUTZAHN, *Chairman*, Public Health Education Section.

Does the Press Want Health Statistics? GEORGE H. VAN BUREN, Supervisor, Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

Local Publicity Use of Statistics from National and State Sources. H. J. SHELLEY, M.D., Health Officer, Middletown, N. Y.

Safeguards in Publicity Uses of Statistics. A. W. HEDRICH, Sc.D., Associate in Biostatistics, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Discussion.

Conducted Tour of the Exhibits.

Wednesday, 9:30 A.M.

PUBLIC HEALTH NURSING

Second Session—Lincoln Room, Lincoln Hotel

TEAM-PLAY BETWEEN PUBLIC HEALTH NURSES AND THE MEDICAL PROFESSION

W. W. BAUER, M.D., Director, Bureau of Health and Public Instruction, American Medical Association, Chicago, Ill.

Discussion. M. LOUISE NICOL, R.N., District Supervising Nurse, Division of Child Hygiene and Public Health Nursing, State Department of Public Health, Springfield, Ill.

THE USE OF LAYMEN IN OFFICIAL PUBLIC HEALTH NURSING PROGRAMS

City. J. D. DOWLING, M.D., County Board of Health, Birmingham, Ala.

County. MRS. A. L. BLACKSTONE, Chairman, Waukesha County Health Committee, and Chairman, Committee on Public Welfare, State Federation of Women's Clubs, Waukesha, Wis.

State. MRS. ARCH TRAWICK, President, State Federation of Women's Clubs, Nashville, Tenn.

Discussion.

Wednesday, 12:30 P.M.

LABORATORY

Luncheon Session—Chateau Room

Section Business.

CHILD HYGIENE

Luncheon Session—Travertine Room, Lincoln Hotel

Section Business.

PUBLIC HEALTH EDUCATION

Luncheon Session—Riley Room

An Experience Meeting

Wednesday, 6:30 P.M.

SECOND GENERAL SESSION

Banquet—Riley Room

MEMORIAL SESSION TO DR. WALTER REED AND HIS ASSOCIATES ON THE YELLOW FEVER COMMISSION

In commemoration of the notable work which made possible the conquest of yellow fever and which was first announced by Dr. Reed at the American Public Health Association meeting in 1900, the Annual Banquet will be a memorial session with fitting exercises and ceremonies. The Surgeon-General of the United States Army, Major General Robert U. Patterson, and Dr. Frederick F. Russell, Director of the International Health Division, The Rockefeller Foundation, will speak.

Thursday, 9:30 A.M.

LABORATORY

Third Session—Milk Sanitation Sub-Session—Palm Room*

(Special Invitation Extended to Members of the International Association of Dairy and Milk Inspectors.)

Presiding: ROBERT S. BREED, PH.D., *Vice-Chairman*, Laboratory Section.

Studies on Acidophilus Therapy. C. N. STARK, PH.D., New York State College of Agriculture, Ithaca, N. Y.

Streptococci Found in Bovine Udders. G. J. HUCKER, PH.D., and P. ARNE HANSEN, New York State Agricultural Experiment Station, Geneva, N. Y.

Microbiological Methods for the Analysis of Butter. E. H. PARFITT, Milk Inspector, Dairy Department, Purdue University, Lafayette, Ind.

SYMPOSIUM ON STANDARD METHODS FOR THE BACTERIOLOGICAL EXAMINATION OF MILK

Bacterial Analysis of Ice Cream. F. W. FABIAN, PH.D., Michigan State College of Agriculture and Applied Science, East Lansing, Mich.

Methods of Examining Dairy Products for Members of the Escherichia-Aerobacter Group. M. H. MCCRADY, Chief of Laboratories, Provincial Bureau of Health, Montreal, Que.

A Comparative Study of Yeast and Beef Extract Media for Use in Routine Milk Control Work. C. S. BOWERS, Department of Health, New Britain, Conn.

The Effect of the Temperature of Incubators upon the Agar Plate Count in Routine Control Work. M. W. YALE, PH.D., and CARL S. PEDERSON, PH.D., Bacteriologist, New York State Agricultural Experiment Station, Geneva, N. Y.

Discussion. ROBERT S. BREED, PH.D., Referee, Chief in Research, New York State Agricultural Experiment Station, Geneva, N. Y.

* Fourth Session—Medical Sub-Session—meeting concurrently in Club Room.

Thursday, 9:30 A.M.

LABORATORY

Fourth Session—Medical Sub-Session—Club Room*

Presiding: ANNA W. WILLIAMS, M.D., *Chairman, Laboratory Section.*

Report of a Series of Cough Plate Examinations for *Hemophilus pertussis*. PEARL KENDRICK, Sc.D., and GRACE ELDERING, State Department of Health Laboratories, Western Michigan Division, Grand Rapids, Mich.

Human Immunization with Tetanus Toxoid. D. H. BERGEY, M.D., Dr.P.H., Professor of Hygiene and Bacteriology, University of Pennsylvania, and S. ETRIS, Philadelphia, Pa.

Vaccine for Immunization Against Smallpox Prepared from Chicken Embryo Cultures. JULIA M. COFFEY, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Report of the Association Committee to Study the Efficacy of Typhoid Vaccines. T. F. SELLERS, M.D., State Department of Health, Atlanta, Ga.

The Isolation from Typhoid Fever Patients and Typhoid Carriers of Strains Which Have Properties Corresponding to Those of Certain Variants of *B. Typhosus*. RUTH GILBERT, M.D., and MARION B. COLEMAN, State Department of Health, Albany, N. Y.

Relationship of *Shigella Alkalescens* to Other Members of the *Shigella* Group. HENRY WELCH, Ph.D., Research Biologist, and FRIEND LEE MICKLE, Director, Bureau of Laboratories, State Department of Health, Hartford, Conn.

Production of Antitoxins by Means of Bacteriophage. N. W. LAREUM, Ph.D., Immunologist, State Department of Health, Lansing, Mich.

The Pathogenicity of Certain Species of *Monilia* for Laboratory Animals. W. D. STOVALL, M.D., State Hygienic Laboratory, Madison, Wis.

Practical Method for Public Health Laboratory Diagnosis of Infectious Syphilis. HERBERT E. MCDANIELS, Research Laboratories, State Department of Public Health, Chicago, Ill.

A Survey of One Thousand Gonococcus Complement-Fixation Tests Performed with the Serums of Female Patients in an Outpatient Clinic. WALTER M. BRUNET, M.D., and B. S. LEVINE, Ph.D., Urological Division and the Clinical Laboratory, Public Health Institute, Chicago, Ill.

* Third Session—Milk Sanitation Sub-Session—meeting concurrently in Palm Room.

HEALTH OFFICERS

Third Session—Assembly Room

The Evaluation of Various Procedures in Diphtheria Control. HERMAN N. BUNDESEN, M.D., President, Board of Health, Chicago, Ill.

Discussion. JAMES ROBERTS, M.D., Medical Officer of Health, Hamilton, Ont.

Developments in Health Administration in the Province of Quebec. ALPHONSE LESSARD, M.D., Director, Provincial Bureau of Health, Quebec, Que.

Medical Participation in the Program of the W. K. Kellogg Foundation. STUART PRITCHARD, M.D., Battle Creek, Mich.

The Sanitary Supervision of Food Handling Establishments. SEVERANCE BURPAGE, Associate Professor, Department of Bacteriology and Public Health, University of Colorado, Denver, Colo.

Thursday, 9:30 A.M.

CHILD HYGIENE SECTION, AMERICAN SOCIAL HYGIENE
ASSOCIATION AND AMERICAN ASSOCIATION OF
SCHOOL PHYSICIANS

Joint Session—Chateau Room

CONGENITAL SYPHILIS

Presiding: THURMAN B. RICE, M.D., Professor of Bacteriology and Pathology, Indiana University, School of Medicine, Indianapolis, Ind.

Medical Aspects. P. C. JEANS, M.D., Department of Pediatrics, University of Iowa Medical School, Iowa City, Ia.

What Can Be Done Regarding Congenital Syphilis Among School Children?
DON W. GUDAKUNST, M.D., Director, School Health Service, Department of Health, Detroit, Mich.

The Prevention of Congenital Syphilis. JAMES R. McCORD, M.D., Department of Obstetrics and Gynecology, Emory University School of Medicine, Atlanta, Ga.

Discussion. WALTER CLARKE, M.B., Director, Division of Medical Measures, American Social Hygiene Association, New York, N. Y.

PUBLIC HEALTH ENGINEERING SECTION AND THE CENTRAL
STATES SEWAGE WORKS ASSOCIATION

Joint Session—Riley Room

Presiding: C. K. CALVERT, *Chairman*, Central States Sewage Works Association.

Recent Advances in the Chemical Treatment of Sewage. F. W. MOHLMAN, Director of Laboratories, Sanitary District of Chicago, Chicago, Ill.

Sewage Sludge Gas Utilization. C. E. KEEFER, Bureau of Sewers, Department of Public Works, Baltimore, Md.

Mechanization of Sewage Treatment Works. E. B. BESSELIÈVRE, Sanitary Engineer, The Dorr Company, New York, N. Y.

The Treatment of Trade Wastes. L. F. WARRICK, State Sanitary Engineer, State Board of Health, Madison, Wis.

VITAL STATISTICS

Third Session—Empire Room

The Economic Depression and Health and Sickness in Families of the Unemployed in Ten Cities. G. Sr. J. PERROTT, Consultant, and SELWYN D. COLLINS, Ph.D., Senior Statistician, U. S. Public Health Service, Washington, D. C.

Have You Used Your 1930 Census Data to the Fullest Extent? MARY V. DEMPSEY, Washington, D. C.

Brief Announcements of Recent Work and Problems.

Display of a Convenient Cumulative Index to U. S. Vital Statistics. J. V. DEPORTE, Ph.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Thursday, 9:30 A.M.

VITAL STATISTICS (Cont.)

Third Session—Empire Room

Some Adventures as a Registration Consultant in Roumania. W. THURBER FALES, Sc.D., State Registrar, State Board of Health, Montgomery, Ala.

Residence Allocation Studies in Ohio. P. G. BECK, University of Ohio, Columbus, O.

Occupational Mortality. JESSAMINE S. WHITNEY, Statistician, National Tuberculosis Association, New York, N. Y.

A Post-mortem of the 1933 Vital Statistics Meetings. Suggestions for Future Programs.

Discussion opened by: GEORGE H. VAN BUREN, Supervisor, Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

Thursday, 2:30 P.M.

LABORATORY

Fifth Session—Sanitation Sub-Session—Chateau Room

WATER AND SEWAGE

Presiding: M. H. MCCRADY, Chief of Laboratories, Provincial Bureau of Health, Montreal, Que.

Differential Reactions in the Colon Group of Bacteria. MAX LEVINE, PH.D., S. S. EPSTEIN, and R. H. VAUGHN, Department of Bacteriology, Iowa State College, Ames, Ia.

Open Forum on Standard Methods for Detection of Members of Coli-Aerogenes Groups of Organisms in Water.

Discussion Opened by: C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

Some Observations on the Germicidal Efficiency of Chloramine-T. D. B. CHARLTON and MAX LEVINE, PH.D., Department of Bacteriology, Iowa State College, Ames, Ia.

INDUSTRIAL HYGIENE

Third Session—Club Room

Occupational Disease Legislation. ANDREW J. FARRELL, Attorney-at-Law, Chicago, Ill.

Pulmonary Asbestosis. JOHN DONNELLY, M.D., Superintendent, Mecklenburg Sanatorium, Huntersville, N. C.

Flight Fatigue. WADE HAMPTON MILLER, M.D., Medical Examiner, Department of Commerce, Aeronautics Branch, Lieutenant Commander, Medical Corps, U. S. Naval Reserve, Flight Surgeon, Kansas City, Mo.

Thorium as a Hazard in Roentgenology. R. POMERANZ, M.D., Associate Roentgenologist, Beth Israel Hospital, Newark, N. J.

A New X-Ray Mass-Procedure for the Discovery of Early Tuberculosis in Industry. MARGARET W. BARNARD, M.D., Medical Director, Bellevue-Yorkville Health Demonstration, New York, N. Y.

Thursday, 2:30 P.M.

FOOD AND NUTRITION SECTION AND INTERNATIONAL ASSOCIATION OF DAIRY AND MILK INSPECTORS

Joint Session—Riley Room

Presiding: CARL R. FELLERS, PH.D., *Chairman*, Food and Nutrition Section, and HORATIO N. PARKER, *President*, International Association of Dairy and Milk Inspectors.

Natural and Induced Variations in the Vitamin Values of Milk. PROFESSOR HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

Report of the Committee on Food Value of Milk (International Association of Dairy and Milk Inspectors). IRA V. HISCOCK, Professor of Public Health, Yale University, New Haven, Conn.

Report of the Committee on Inter-state Shipment of Cream (International Association of Dairy and Milk Inspectors). H. E. BREMER, State Department of Agriculture, Montpelier, Vt.

Report of the Committee on Milk and Dairy Products (American Public Health Association). *Chairman*, WILLIAM B. PALMER, Milk Inspection Association of the Oranges, Orange, N. J.

The Quality of Milk Pasteurized by High-Temperature, Short-Time and 30-Minute Holding Methods. M. W. YALE, PH.D., New York State Agricultural Experiment Station, Geneva, N. Y.

Chlorine Sterilizers in Dairies (International Association of Dairy and Milk Inspectors). M. J. PRUCHA, PH.D., Professor of Dairy Bacteriology, University of Illinois, Urbana, Ill.

PUBLIC HEALTH EDUCATION

Third Session—Travertine Room, Lincoln Hotel

IS THERE A COMMON OBJECTIVE IN PUBLIC EDUCATION AROUND WHICH
ALL HEALTH ORGANIZATIONS CAN RALLY?

A Panel Session.

Foreman of the Jury: C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

Jurymen:

H. E. KLEINSCHMIDT, M.D., Director, Health Education, National Tuberculosis Association, New York, N. Y.

LEWIS H. CARRIS, Managing Director, National Society for the Prevention of Blindness, New York, N. Y.

WILLIAM F. SNOW, M.D., General Director, American Social Hygiene Association, New York, N. Y.

HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

MARJORIE DELAVAN, Director, Bureau of Education, State Department of Health, Lansing, Mich.

BLEECKER MARQUETTE, Executive Secretary, Public Health Federation, Cincinnati, O.

Thursday, 2:30 P.M.

PUBLIC HEALTH NURSING SECTION, INDIANA STATE NURSES
ASSOCIATION AND INDIANA LEAGUE OF
NURSING EDUCATION

Joint Session—Assembly Room

Presiding: BEATRICE GERRIN, R.N., Superintendent of Nurses, Indianapolis City Hospital Nursing School, Indianapolis, Ind., and ELSEBETH H. VAUGHAN, R.N., *Chairman*, Public Health Nursing Section.

QUALITY NURSING

Good Health as a Factor. JOHN SUNDWALL, M.D., Director, Division of Hygiene and Public Health, University of Michigan, Ann Arbor, Mich.

Discussion.

The Undergraduate Curriculum as a Factor. MARY BEARD, R.N., Associate Director, International Health Division, Rockefeller Foundation, New York, N. Y.

Discussion.

THE SECOND INSTITUTE ON HEALTH EDUCATION

DR. IAGO GALDSTON, *Director*

Under the auspices of the Public Health Education Section

Theme: "The Psychology of Health Education."

Arrangement: There will be five sessions; Saturday morning, Saturday afternoon, Sunday morning, Sunday afternoon and Monday morning. Morning sessions begin at 9 and end at 12; afternoon sessions begin at 2 and end at 5. Three of the sessions will be didactic conferences concerning:

- a. Why the psychology of health education?
- b. The psychologic nature of the recipient of health education
- c. Fundamental principles relative to:
 1. Arresting attention
 2. Enlisting sympathy
 3. Imparting information
- d. Meaning and mechanism of motivation
- e. Practical demonstrations; the application of the outline of psychologic principles to health education instruments; the spoken text, the printed text and graphic material.

Round Table, Clinic: One session will be a "round table" with the student body forming three separate groups. The students will be given an opportunity to practise evaluating material which they as a body have brought, along principles indicated. Each group will hold a conference on a definite amount of assigned material. Each group will have a reporter who will deliver to the student body as a whole the judgment of the round table at the final clinic session. The reporters will participate with the teaching staff in evaluating the educational material submitted.

Teaching Staff: The teaching staff consists of Dr. IAGO GALDSTON, New York Academy of Medicine, Dr. H. E. KLEINSCHMIDT, National Tuberculosis Association, BERTRAND BROWN, Milbank Memorial Fund, and the student body.

Enrollment: Any person engaged full time or part time in health education activities is eligible for enrollment in the Institute, upon application to the office of the American Public Health Association and upon payment of the Institute fee of \$5.00. The Institute faculty reserves the right to limit enrollments to sixty, applications to be accepted in the order received. Every participant in the Institute will be required to submit educational material for review and analysis. Such material may be finished pieces of work or lay-outs and plans in preparation.

MEETINGS OF OTHER ORGANIZATIONS

CONFERENCE OF STATE SANITARY ENGINEERS

All day Saturday, October 7, Palm Room.

Monday A.M., Palm Room.

Monday P.M., Joint Session with the Public Health Engineering Section, Palm Room.

Tuesday Evening, Annual Engineers' Stag Dinner Party, Travertine Room, Lincoln Hotel.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

For complete program see pages 970 and 971.

MUNICIPAL SANITATION EDITORIAL BOARD

Monday Noon, Luncheon, English Parlor.

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

Monday Evening, Dinner Session, Chateau Room

The Annual informal dinner of the Association of Women in Public Health will occur October 9, 1933, at the Claypool Hotel in the Chateau Room.

Detailed information will be available at the registration desk.

It is hoped that members arriving early for sessions of the American Public Health Association will visit the Florentine Room in the Claypool Hotel, where the organization will have informal headquarters. There are a number of important questions to be discussed and formulated for presentation at the dinner meeting.

A committee on future policies and plans, Dr. Mary Lakeman, Chairman, will be glad to have your suggestions, as will the nominating committee.

Officers of the Association aided by a local committee will give all possible assistance.

You are asked to obtain your dinner ticket at the A.P.H.A. registration desk, on your arrival, to facilitate arrangements. As members will wish to attend the First General Session of the American Public Health Association, it will be necessary to arrive promptly at the hour given on the card. A pleasant surprise is planned for the dinner.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

Tuesday, 8 A.M., Breakfast, Louis XV Parlor.

DELTA OMEGA

NATIONAL COMMITTEE OF HEALTH COUNCIL EXECUTIVES

Tuesday Noon, Luncheon, English Parlor.

JOHNS HOPKINS UNIVERSITY ALUMNI

Wednesday, 8 A.M., Breakfast.

AMERICAN JOURNAL OF PUBLIC HEALTH

AMERICAN SOCIAL HYGIENE ASSOCIATION

Thursday A.M., Joint Session with the Child Hygiene Section and American Association of School Physicians, Chateau Room.

CENTRAL STATES SEWAGE WORKS ASSOCIATION

Thursday A.M., Joint Session with the Public Health Engineering Section, Riley Room.

INTERNATIONAL ASSOCIATION OF DAIRY AND MILK INSPECTORS

Thursday P.M., Joint Session with the Food and Nutrition Section, Riley Room.

Friday and Saturday, October 13 and 14.

INTERNATIONAL SOCIETY OF MEDICAL HEALTH OFFICERS

SIXTH ANNUAL MEETING

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

(Unless otherwise indicated, all sessions will be held in the Roof Garden of the Hotel Severin)

Monday, 9:30 A.M.

Joint Session with the Public Health Nursing and Child Hygiene Sections of the American Public Health Association

Riley Room, Claypool Hotel

(For Program see page 951)

Monday, 2:00 P.M.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Address of the President of the American Association of School Physicians.
J. BRUCE McCREARY, M.D., Deputy State Secretary of Health, Harrisburg, Pa.

MEDICAL LEADERSHIP IN HEALTH SERVICE

By State Medical Societies. R. R. FERGUSON, M.D., Illinois State Medical Society, Chicago, Ill., and THOMAS P. FARMER, M.D., New York State Medical Society, Syracuse, N. Y.

By Educational Authorities. A. O. DEWEESE, M.D., Director of Health, Kent State Normal College, Kent, O., and W. D. GATCH, M.D., Indiana University School of Medicine, Indianapolis, Ind.

What Qualifications Should the Director of School Health Education and School Health Service Have? FREDERICK L. PATRY, M.D., Neuropsychiatrist, State Education Department, Albany, N. Y.

Discussion. JOHN SUNDWALL, M.D., University of Michigan, Ann Arbor, Mich.

Tuesday, 12:15 P.M.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS AND INTERNATIONAL
SOCIETY OF MEDICAL HEALTH OFFICERS

Joint Luncheon Session

A Close-Up of Some Aspects of School Medical Inspection (A Preliminary statement on the results of a study of physical defects and the reasons for non-correction in the schools in New York City). RAYMOND FRANZEN, Ph.D., Research Director of the Study, American Child Health Association, New York, N. Y.

Discussion. HAVEN EMERSON, M.D., Member of Advisory Committee of the Study, New York, N. Y.

Tuesday, 2:00 P.M.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

SCHOOL MEDICAL INSPECTION AND HEALTH SERVICE

In Honolulu. FRED K. LAM, M.D., Honolulu, T. H.

In LaSalle, Illinois. ARLINGTON AILES, M.D., Hygienic Institute, LaSalle, Ill.

Annual Medical Examination for Teachers. J. L. DELAMATER, M.D., St. Joseph, Mo., and H. W. FUDGE, M.D., Elmira, N. Y.

Mental Hygiene Child Guidance by a Part-Time Psychiatrist. HAROLD S. HULBERT, M.D., School Psychiatrist for Gary and East Chicago, Ind.

Prevalence and the Permanence of Defective Hearing as It Exists in School Children. WALTER S. CORNELL, M.D., Director of Medical Inspection, Philadelphia, Pa.

Wednesday, 2:00 P.M.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS AND INTERNATIONAL
SOCIETY OF MEDICAL HEALTH OFFICERS

Joint Session

Childhood Tuberculosis Up to Now. J. A. MYERS, M.D., Department of Public Health, Minneapolis, Minn., and WALTER RATHBUN, M.D., Cassadaga, N. Y.

Discussion. JAMES A. KEENAN, Boston, Mass.

State Chapters of American Association of School Physicians. J. M. QUIGLEY, M.D., Clearfield, Pa.

The Factor Body Width Plays in Height, Weight, Age (Preliminary Report). C. L. OUTLAND, M.D., School Medical Director, Richmond, Va.

Thursday, 9:30 A.M.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Joint session with the Child Hygiene Section of the American Public Health Association and the American Social Hygiene Association.

Travertine Room, Lincoln Hotel

(For Program see page 965)

INDIANA STATE NURSES ASSOCIATION AND INDIANA LEAGUE
OF NURSING EDUCATION

The program for these meetings, to be held on October 12, 13, and 14, lists some interesting topics and speakers.

Their joint session on Thursday afternoon with the Public Health Nursing Section is given on page 968 of this JOURNAL. The subject of the General Session on Friday morning is "Quality Nursing." It will be treated from three angles—the hospital, the public health field, and the home. GRACE ROSS, Director of Nursing Service of the Detroit Department of Health, will speak for the public health nurse.

One of the round table luncheons scheduled for Thursday noon will be presided over by BEATRICE SHORT, *Chairman* of the Public Health Section. The topic for discussion is "What Can Be Done Next Year in Indiana to Further the Interest of Public Health Nurses as a Professional Group?" ALMA HAUPT, Associate Director, National Organization for Public Health Nursing, will present the paper.

At the general session on Friday afternoon, DR. J. A. MEYERS will talk on "Tuberculosis Case Finding," and DR. FRANK L. RECTOR on "Cancer." At a dinner that evening, CLARA D. NOYES, Director of the Nursing Service, American Red Cross, is to be the speaker.

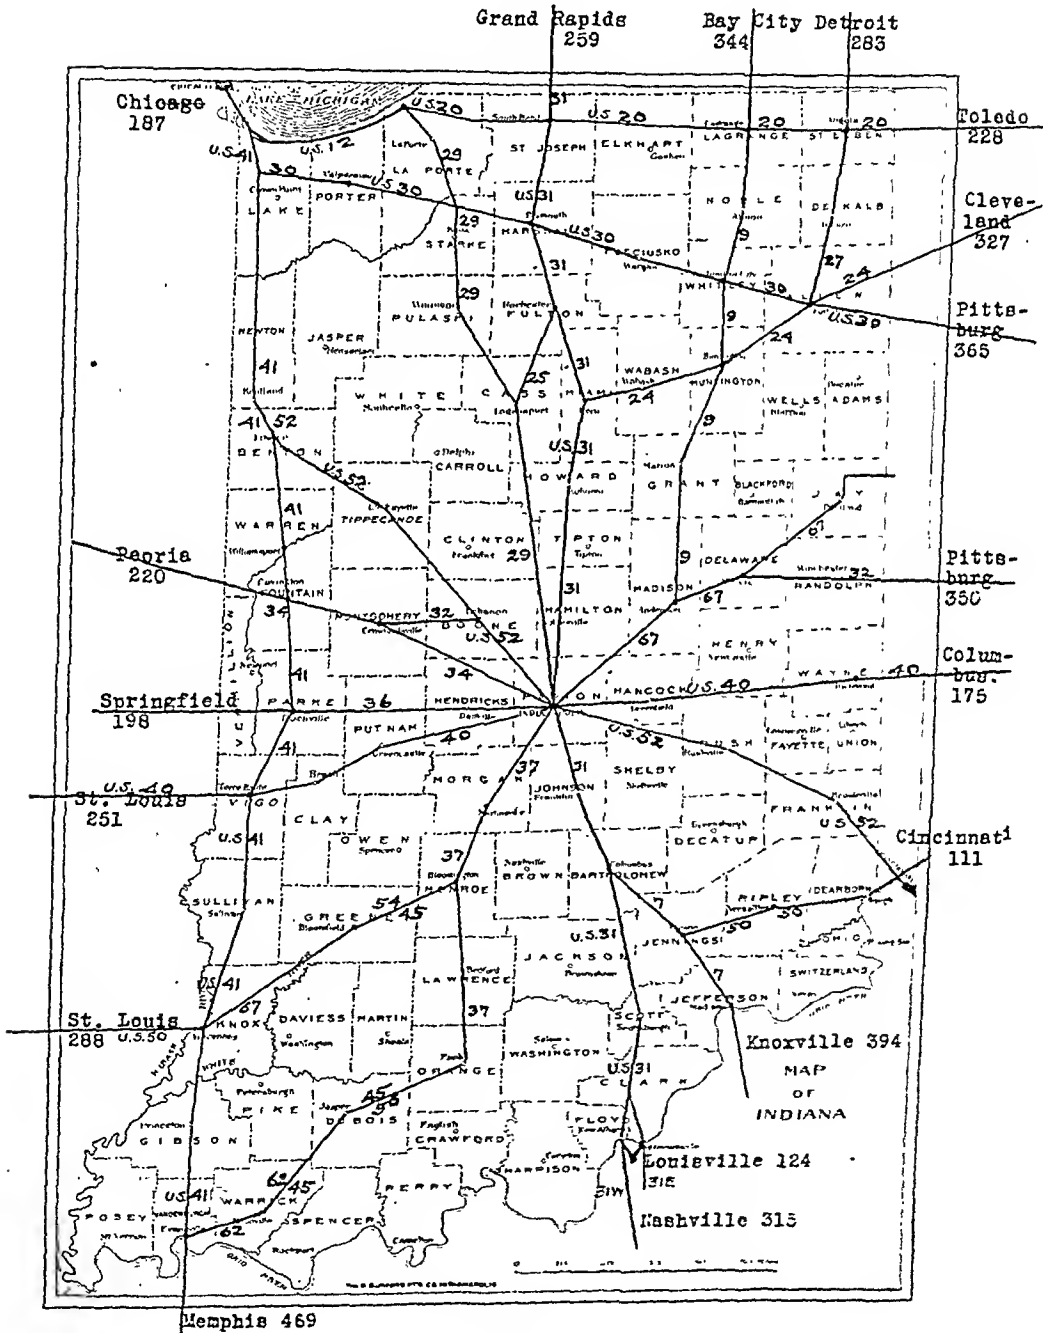

Saturday morning will be taken up with committee and section reports and an address on "Present Problems and Needs of Indiana" by the President of the Indiana State Nurses' Association, LULU V. CLINE.

Members of the American Public Health Association are invited to attend the sessions.

ASSOCIATION NEWS

Main Indiana Highways to Indianapolis
with road numbers indicated

MARGIN FIGURES INDICATE MILEAGES FROM INDIANAPOLIS

DID YOU ATTEND THE INDIANAPOLIS ANNUAL MEETING IN 1900?

ONE of the outstanding events of our Indianapolis meeting this year, as has been mentioned before, is the Memorial Session to Dr. Walter Reed and his associates on the Yellow Fever Commission.

Dr. William F. King, our host at Indianapolis, is assembling a list of present members of the Association who attended the Annual Meeting in 1900. Letters have been sent to members on the membership list for the year 1900; but it is possible that the old records are not entirely accurate and that some

who are members now and were present at the meeting when Dr. Reed read his famous paper joined after that year.

If you attended the Indianapolis Annual Meeting in 1900, please notify the Association office. Any memories you have of the occasion will be helpful, particularly if you were so fortunate as to hear Dr. Reed. If you are planning to attend the Indianapolis meeting this year, please indicate that as well, so you may be paid some honor, too, when the Association meets in banquet session on Wednesday evening, October 11.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

- Joseph F. Bredeck, M.D., D.P.H., Municipal Courts Bldg., St. Louis, Mo., Health Commissioner
 Claude W. Chamberlain, Ph.D., 6124 Cermak Road, Cicero, Ill., Assistant Superintendent of Social Hygiene, Division of Communicable Diseases, State Department of Health
 Francis B. Galbraith, M.D., 2226 Santa Clara Ave., Alameda, Calif., Health Officer
 Verne K. Harvey, M.D., C.P.H., State House Annex, Indianapolis, Ind., Director, Division of Public Health, Indiana State Department of Commerce and Industry
 William H. Oates, B.Sc., M.D., 402-1st National Bank Annex, Mobile, Ala., Member of Board of Health of Mobile County
 Tan Poh Seong, M.D.H., Kuala Belait, Brunei, S. S., Health Officer (Assoc.)
 George L. Stivers, M.D., Belmont Hospital, Worcester, Mass., Medical Director, Belmont Hospital

Laboratory Section

- Chester S. Bowers, B.S., Board of Health Laboratory, City Hall, New Britain, Conn., Director of Laboratory
 Harold M. B. Lineback, M.S. in P.H., 1537 Cone St., Toledo, Ohio, Bacteriologist

Vital Statistics Section

- Ruth R. Puffer, A.B., State Department of Health, Nashville, Tenn., Statistician

Public Health Engineering Section

- J. G. Beacham, B.S.C.E., P. O. Box 522, Athens, Ga., City Engineer and Superintendent of Water Works
 Charles G. Gifford, M.S., 203 Standard Life Bldg., Pittsburgh, Pa., Dairy Inspector

Food and Nutrition Section

- Harry A. Fritschman, 2325 Darby Road, Upper Darby, Pa., Secretary Board of Health, Haverford Township

Child Hygiene Section

- Solomon L. Hermans, M.D., Bowmanstown, Carbon Co., Pa., School Medical Inspector, Palmerton Public Schools
 Harry J. Wieler, M.A., The Hotchkiss School, Lakeville, Conn., Medical Director

Public Health Education Section

- Elwood C. Davis, Ph.D., Pennsylvania State College, State College, Pa., Head of Department of Professional Health and Physical Education
 Margaret H. Jeffreys, 2 Walnut St., Crafton, Pa., Dental Hygienist

George T. Wilhelm, University of Tennessee,
Knoxville, Tenn., Professor of Hygiene and
Director, Department of Student Health
Frank B. Wisner, B.S., M.D., Springfield Hos-
pital, Springfield, Mass., Student (Assoc.)

Public Health Nursing Section

Emma T. Higgins, R.N., P. O. Box 195,
Waukesha, Wis., County Nurse
Clodia E. Johnson, R.N., Hart, Mich., County
Nurse
Maude D. Smith, R.N., 969 N. Marengo Ave.,
Pasadena, Calif., School Nurse
Reba L. Bess, R.N., Box 645, Keyser, W. Va.,
County Nurse

Epidemiology Section

W. Arkell Browne, M.D., 416 City Hall Annex,
Richmond, Va., Epidemiologist, Bureau of
Health

Unaffiliated

Charles W. Bonyng, M.D., 840 W. 37th St.,
Los Angeles, Calif., Director Laboratories,
Los Angeles County Medical Commission
Raymond D. Fear, M.D., Dr.P.H., 52 South
St., Stamford, Conn., Health Commissioner
Arthur E. McClue, M.D., State Health Dept.,
Charleston, W. Va., State Health Commis-
sioner

ADDITIONAL APPLICANTS FOR FELLOWSHIP

HEALTH OFFICERS SECTION

James William Bass, M.D., Dallas, Texas
Lloyd Moffitt, M.D., Yakima, Wash.

LABORATORY SECTION

George D. Beal, Phar.D., Ph.D., Pittsburgh,
Pa.
Archie H. Robertson, M.S., Ph.D., Albany,
N. Y.

FOOD AND NUTRITION SECTION

Lawrence W. Bass, Ph.D., New York, N. Y.

N. Y.

PUBLIC HEALTH NURSING SECTION

Sarah R. Addison, R.N., Hartford, Conn.
Naomi Deutsch, R.N., San Francisco, Calif.
Mary E. Edgecomb, Englewood, N. J.
Alma C. Haupt, R.N., New York, N. Y.
Arline R. Mansfield, B.S., Easton, Pa.
Marion W. Sheahan, R.N., Albany, N. Y.

PUBLIC HEALTH ADMINISTRATION

Dairy and Milk Inspectors' Training Course—The growing interest in self-improvement developed by sanitary inspectors of the Los Angeles County Health Department has arrived at the point where they are willing to spend their own time and mileage allowance attending classes of instruction. This was evidenced by the attendance at the Dairy and Milk Inspectors' Training Course given under the supervision of the School of Sanitary Instruction from February 7 to May 23, 1933. Classes were held every Tuesday evening from seven to nine at the East Side Health and Welfare Center, with the exception of three weeks when the entire inspection group was on earthquake emergency duty. Field trips were taken in the evenings or on Saturdays. The scope of the course was limited to the actual operations which a dairy and milk inspector performs, the contributing knowledge being distributed in pamphlet form.

The object of the training program was (1) to standardize procedure, (2) prepare inspectors to pass the approval examination given by the State Department of Agriculture, and (3) for general information. There were nine dairy and milk inspectors and eighteen senior sanitary inspectors who attended classes, twenty-two of whom completed the course and took the final oral and written examination. In addition to the regular class, there were twelve to twenty-eight visitors at each session, the latter merely listening in and taking no part in the discussions, five minute questions, or home work. Some of the inspectors and visitors had to travel a total distance of seventy miles to the Health Center which was a good indication of their interest. This getting-

together of inspectors with state control officials has proven of immense benefit in clarifying dairy inspection procedure and in developing a high morale within the inspection force (a complete list of the subjects discussed will be provided upon request).—Walter S. Mangold, Sanitary Instructor, Los Angeles County Health Department.

Distribution of Dysentery—To distinguish this disease from the common intestinal affections the dysenteric syndrome is defined as being constituted essentially by the presence of abdominal pains, frequent mucous and bloody stools with painful straining and tenesmus. This syndrome may be produced by infection either by *Entamoeba histolytica* or by one of the numerous known forms of *B. dysenteriae*. In the search for amoebiasis a single examination cannot prove with certainty the absence or presence of the amoeba. A single examination may disclose only 44 per cent of carriers while as many as six examinations may be required to uncover 100 per cent of carriers.

A statistical study has been made of the prevalence of dysentery in all sections of the world. Statistics have been gathered from registered cases, from death records, from military and hospital records and other sources. Dysentery appears even in places with a severe climate. For a long time it was thought that amoebic dysentery was the dominating, if not the only, form encountered in the tropical and sub-tropical zones, and that, on the other hand, bacillary dysentery was the only form that occurred in the temperate zones. The increasing use of laboratory methods for the etiological diag-

nosis of the forms of dysentery, and for finding germ carriers, has brought about a change in these traditions. Amoebic dysentery is particularly prevalent in tropical regions but to a lesser degree the *Entamoeba histolytica* is widespread in temperate climates. Bacillary dysentery is not limited to the temperate zone but may even be the predominant type of infection in tropical regions.—*League of Nations Epidemiological Report*, Apr., 1933.

Bellevue-Yorkville Health District—The sixth annual report of the Bellevue-Yorkville health demonstration for 1932 is a document of 68 pages, well mimeographed and interestingly written. The health department's first clinic for preschool children was opened here in 1927, later followed by similar services elsewhere in the city. The first official consultation chest service for private physicians was established in 1929 and the department now operates seven others. A pneumothorax refill service, established in the health center in 1931, has been extended to other sections of the city. A diagnostic cardiac clinic for children, a generalized nursing service, a mental hygiene unit, and a dental service for children are among the other projects which are described.

Of recognized value, too, are the quarterly and yearly compilations and special studies, prepared by the Demonstration's division of records, of vital statistics for the 25 sanitary areas comprising its district. A record of the prevalence of diseases, so localized, makes possible greater efficiency in the direction of preventive activity by the Center.

Health education applying to adults as well as children, living or working in the area has been a feature of the health center work. Expenditures of the Demonstration, besides those of the department of health for medical nursing services, amounted to \$81,647, which was contributed by the Milbank Memorial Fund.

Whooping Cough Vaccination—Many authorities feel that if vaccine is given early in the catarrhal stage some good will be effected but when used in the convulsive stage little effect can be expected. There has not been sufficient distinction between the use of whooping cough vaccination for therapeutic and prophylactic purposes. The Faroe Islands, due to their isolation, have long afforded a splendid opportunity for the study of the epidemiology of communicable diseases. Favorable results with vaccination are reported. The vaccine used was made from young strains; the dose was rather large, a total of 22,000 million bacteria; the vaccination was completed shortly before the onset of an epidemic. The mortality in the vaccinated group of nearly 4,000 individuals was but one-sixteenth of the mortality in the non-vaccinated group which included approximately 1,000 individuals. The groups were quite comparable with respect to age, time of epidemic and surrounding conditions. — Thorvald Madsen, *Vaccination Against Whooping Cough*, *J.A.M.A.* 101, 189 (July 15), 1933.

LABORATORY

LABORATORY AIDS IN THE DIAGNOSIS AND SERUM THERAPY OF PNEUMOCOCCUS PNEUMONIA

ALBERT B. SABIN, M.D.

*Department of Bacteriology and Immunology, New York University and
Bellevue Hospital Medical College, New York, N. Y.*

FOR centuries the diagnosis of pneumonia has been made on the basis of certain well known clinical features. However, from the standpoint of prognosis, serum therapy, and epidemiology, the simple clinical diagnosis of pneumonia with its anatomic differentiation into lobar and broncho-pneumonia, has come to be regarded as incomplete without the determination of the etiologic agent. We present recent methods for establishing the etiologic diagnosis and discuss laboratory aids for the control of serum therapy.

Of the pneumococci which are the infecting organisms in about 95 per cent of the pneumonias, approximately 90 per cent fall into 32 distinct and definite types.¹ Of the specific antisera which have thus far been investigated, only Type I serum has been shown to be of definite value, and Type II to have a beneficial effect when administered during the first 3 days of the disease. The value of sera against some of the recently classified types is being studied. Although specific therapy is thus limited, it is nevertheless important to carry routine determinations through all the classified types of pneumococci, not only as an aid to prognosis, but also, epidemiologically, to supply data as to the relative incidence of the various types in different parts of the world. For this latter reason it would also be advisable to make pneumonia reportable not merely as "lobar" or "broncho"—but with a complete etiologic diagnosis as well.

The determination of the infecting organism may be accomplished in four ways: (1) by the isolation of the organism; (2) by the demonstration in sputum, urine, or blood of the specific products of its growth; (3) by the rate of agglutinin neutralization in cases receiving polyvalent serum; and (4) by the specific immune bodies which the patient develops during convalescence.* The isolation of the organism is commonly attempted from the blood by culture, and from the sputum preferably by mouse inoculation. When, as in certain adult patients, and particularly in children, sputum cannot be obtained, one may incubate a throat swab in broth for 2-3 hours, and then inject the broth into a mouse. Although many reliable methods for typing pneumococci have been introduced, I shall confine myself to the microscopic method which I described in 1929²; it has since been widely used and found to be rapid, reliable, and particularly useful in the differentiation of all known types of pneumococci on account of the small quantities of antigen and serum required.

The method is as follows: Three to 4 hours after mouse inoculation with a good sample of sputum there are usually sufficient pneumococci in the peritoneal

* Since this paper was read in October, 1932, a method of pneumococcus typing directly from the sputum has been introduced and found to be perhaps the most rapid, simple, and practical of any employed thus far.

Sabin, A. B. Immediate Pneumococcus Typing Directly from Sputum by the Neufeld Reaction. *J.A.M.A.*, 109:1584-1586 (May 20), 1933.

exudate to permit a microscopic test. The mouse is not killed, the exudate being drawn off with a glass capillary tube. Drops of the exudate are mixed with drops of a 1:10 dilution of the various typing sera; after drying, the smears are stained and examined with the oil immersion lens. A positive reaction is indicated by a clumping of the pneumococci in one of the smears (Figure I). In performing a complete typing for all the 32 types, the sera may be combined into 8 groups; for example, Group A may contain the sera of Types I-IV in final dilution of 1:10 or 1:20; Group B, sera Types V-VIII, etc. When agglutination occurs in one of the groups, 4 smears are made with the constituent sera of that group, to determine the one type; with no clumping in any of the groups, the pneumococcus is termed unclassified. Sometimes, agglutination is observed in more than one group or type serum, and it is then necessary to repeat smears with higher dilutions (1:20, 1:40, 1:60, etc.) of the sera in question, until only one serum produces agglutination. After death of the mouse it is well to confirm the type by a culture of the heart's blood.

When, as occasionally happens, more than one type of pneumococcus is isolated, it is important to keep the cultures until the patient convalesces, if he does, and then test the patient's blood against these cultures; the type that is agglutinated by the patient's blood is the one that most likely was the infecting organism. Only when more than one is specifically agglutinated by the convalescent blood, is a mixed infection definitely established.

When sufficient sputum is available, and if it is coagulable, in addition to mouse inoculation a Krumwiede test should be tried, since when it is definitely positive it is the most rapid and reliable of all methods. In severe cases it is worth while to do a precipitin test on a clear sample of urine.

Microscopic Typing of Blood Cultures—If the growth is not sufficiently heavy in the original culture, the broth is centrifuged, and the sedimented organisms then suspended in a little of the supernatant fluid. Typing is performed with this suspension.

Microscopic Typing of Spinal and other Pneumococcus-Infected Fluids—In pneumococcus meningitis, there are

FIGURE I—MICROSCOPIC AGGLUTINATION IN STAINED SLIDE TYPING METHOD (SABIN). (Left) Mouse peritoneal exudate mixed with heterologous type serum. No agglutination of pneumococci; (Right) Same mixed with homologous type serum. Observe agglutination of pneumococci.

Acknowledgment: The author is indebted to Dr. Jesse G. M. Bullock for the use of these figures.

in their blood was determined by a rapid microscopic method.⁴ In this method two drops of blood are obtained on a slide; one is mixed with a drop of Type I pneumococcus vaccine, and the other with a drop of Type II vaccine. After drying in air, the smears are de-hemoglobinized and fixed by immersion into Ruge's solution (2 per cent formaldehyde containing 1 per cent glacial acetic acid) for 20 seconds. After rinsing in water, the preparation is stained. An analysis of Charts I and II reveals that even in the absence of a 'detectable' bacteremia, there is a continued disappearance of the homologous agglutinins until an excess is established in the circulation. It thus appears that this method can be used not only for confirming the type of infecting pneumococcus but also primarily to establish it. In many communities, where 50-60 per cent of all pneumonias are caused by pneumococcus Types I and II, and in the absence of facilities for a rapid determination of type, it seems advisable to administer a certain amount of bivalent

(Types I and II) antipneumococcic serum and 2-3 hours later to perform an agglutination test with the patient's blood. When the infecting pneumococcus is neither Type I nor II, the blood will contain both Type I and II agglutinins; the presence of Type II agglutinins only indicates a Type I infection and *vice versa*. Since the rapid disappearance of homologous agglutinins depends upon the activity of the infection, a very mild infection may not be detected by this method. Similarly, late in the disease, sometimes even a day or two before the crisis, the patient will have produced his own homologous agglutinins, which persist long after the passively introduced heterologous agglutinins have disappeared.

It is of course obvious that the use of this method either for the confirmation or the primary establishment of the type of infection cannot properly be carried out unless the respective agglutinin titres of the bivalent serum are known. Table I shows the agglutinin titres of five concentrated and refined

CHART 2—Reaction of a patient with Type I pneumonia (positive blood culture) to serum therapy.

TABLE I
RELATIONSHIP BETWEEN THE CONTENT OF "PROTECTIVE ANTIBODIES" AND
AGGLUTININS IN CONCENTRATED SERA

| Concentrated Preparation | Protective Units per c.c. | | Agglutination of Undiluted Serum with Pneumococcus Type | | | Last Dilution (Using Horse Serum) Giving Positive Agglutination of Pneumo- coccus Type | |
|-----------------------------|------------------------------|-------|---|----|-----|--|-------|
| | | | | | | I | II |
| | I | II | I | II | III | | |
| Banzhaf 14-485 | < 20 | 1,000 | + | — | + | | 1,000 |
| Banzhaf 36 | < 20 | 2,000 | + | — | + | | 1,200 |
| Lederle | 3,000 | 1,500 | — | — | + | 800 | 1,000 |
| Felton 37 | 1,500 | 1,000 | — | — | + | 400 | 400 |
| Felton 39 | 2,000 | 1,000 | — | — | + | 400 | 400 |
| Felton 45B | 3,000 | 1,500 | — | — | + | 800 | 1,200 |
| Felton 47 | 3,000 | 1,000 | — | — | + | 1,200 | 1,400 |

bivalent sera (Types I and II). The important thing to note is the disproportion between the number of mouse protective units and the agglutinin titres for the two types of antibody, and the relatively higher agglutinin content per mouse protective unit of the Type II antibody. The dose of serum which is administered must necessarily contain sufficient agglutinins to render them detectible after their dilution with the body fluids; however, in making this calculation, it has been shown that human blood increases the agglutinin titre of a serum about 2-3 times by a so-called conglutinin effect.⁴

The proper control of the dosage of antipneumococcic serum necessarily depends upon a correct understanding of its therapeutic mechanism. The current opinion is that the action of the serum is purely antibacterial, and that its potency can be correctly expressed in terms of its mouse protective capacity. Recently,⁵ I have been able to show that in addition to the antibacterial bodies, standard antipneumococcic sera contain also a so-called "non-antibacterial" factor which plays an important rôle in the defense against pneumococcus infection. It was apparent from this that the standardization of dosage in mouse protective units

was misleading and inaccurate, because an important therapeutic action of the serum was thus disregarded. The standardization of the potency of antipneumococcic serum by its therapeutic effect on the experimental dermal pneumococcus infection in rabbits seems to be considerably more reliable as it measures the antibacterial as well as the non-antibacterial factors.

In a study⁶ of the action of specific serum on the Type I pneumococcus dermal infection in rabbits, it was observed that the therapeutic effect did not depend entirely upon either the antibacterial factor, *i.e.*, mouse protective antibody, or the non-antibacterial factor alone. It was further shown that in a minimally effective therapeutic dose, the absolute concentration of either factor was inconstant and varied with the relative concentration of the other; when a relatively larger amount of antibacterial bodies is acting, less of the non-antibacterial factor seems to be necessary and conversely when more of the non-antibacterial factor is available, less of the antibacterial bodies is required. However, to render and maintain the blood stream antibacterial is one of the primary aims of serum therapy. To do this requires widely varying amounts of serum in different

patients depending upon the presence and degree of bacteremia, and the amount of soluble neutralizing substances that are liberated into the circulation. The intact organisms as well as the soluble neutralizing bodies are responsible for the rapid disappearance of the homologous agglutinins. When homologous agglutinins are not demonstrable in the patient's blood, the blood may or may not be antibacterial; when they are demonstrable, however, one can be more certain. It is for this reason, that the microscopic agglutinin test previously described, can be of aid in the control of dosage. When this test is used, sufficient serum must be administered within the shortest possible time to render the patient's blood positive for homologous agglutinins. The quantity of additional serum which is then to be administered should be controlled not only by the amount required to maintain the blood antibacterial, but also by the condition of the patient so that the dose of the non-antibacterial factor may also be adequate. In the experimental disease of rabbits it has been observed that when

they are treated with a dose of serum which contains sufficient antibacterial bodies but an inadequate amount of the non-antibacterial therapeutic factor, most of the rabbits die; the additional injection of an adequate amount of this non-antibacterial factor, however, can save them from death.

VITAL STATISTICS

Provisional Summary of Mortality from Automobile Accidents in the United States Registration Area, 1932—Provisional figures, issued by the Census Bureau, show that 26,168 deaths from automobile accidents were recorded in 1932 in the death registration area of Continental United States (exclusive of the state of Utah), in comparison with 29,885 deaths in the same area in 1931. The death registration area, comprising 95.9 and 95.8 per cent of the total population of Continental United States in 1932 and 1931 respectively, registered automobile accident mortality rates of 21.9 in 1932 and 25.1 in 1931.

Considering the states by geographic divisions, the Pacific group had the highest death rate in 1932 as well as in 1931, the respective rates being 33.2 and 37.2. Next in order of groups in 1932 are the Mountain (26.6), the East North Central (24.3), and the Middle Atlantic (22.3)—each higher than the rate for the registration area. The groups having the lowest rates were the East South Central (15.0), the West South Central (16.1), and the West North Central (17.6).

Considering the states separately, those with the highest death rates from automobile accidents in 1932 were Nevada (63.4), District of Columbia

(38.7), California (36.9), Arizona (35.7), and Wyoming (34.5), while in 1931 the order was Nevada (68.5), Wyoming (43.0), California (40.5), Florida (34.4), and Arizona (33.6). The lowest mortality rates from this cause in 1932 were for North Dakota (8.3), Mississippi (11.4), Arkansas (13.9), South Dakota (14.1), and New Hampshire (15.0). States with the lowest rates in 1931 were in order of rate—Mississippi (14.0), North Dakota (16.1), South Dakota (16.6), and Oklahoma and Rhode Island (each 16.7).

In the group of 92 cities of 100,000 or more population, there were 8,573 deaths, or a rate of 22.8 per 100,000 population, from automobile accidents in 1932 as compared with 9,825 deaths, or a rate of 26.6 in 1931. The cities which had the highest mortality rates from automobile accidents in 1932 were Camden (65.4), Nashville (45.9), San Diego (41.6), Jacksonville and Tacoma (each 41.5).

The total number of deaths within a city should not be taken as the measure of the automobile hazard. The location of the city, the volume of automobile traffic, the hospital facilities, and other factors, should be considered in connection with the total number of deaths. A better measure of the automobile hazard within a city is the number of fatalities which result from accidents therein. Camden, N. J., serves as an excellent illustration of both of these conditions. Of the 78 deaths in this city due to automobile accidents, only 27 resulted from accidents within the city. The total death rate due to automobile fatalities was 65.4, while that due to accidents within the city of Camden was only 22.7. Similarly Trenton had a total mortality from automobile accidents of 33.0 and a death rate from automobile accidents within the city of 9.7 in 1932; other cities—Nashville with corresponding

rates of 45.9 and 22.9, Reading with 31.3 and 11.6, Wilmington with 33.8 and 16.9, and Richmond with 36.1 and 17.3—also demonstrate the difference between these two death rates.—U. S. Department of Commerce. Bureau of the Census.

Vital Statistics for Germany in 1932—Reports of vital statistics for Germany in 1932 show reductions in marriages, live births, stillbirths, general mortality and infant mortality. In view of the great hardships which the country has suffered economically, it is remarkable that the decreases in births and marriages were no greater and that there were reductions in both the general and the infant mortality.

Marriages in Germany during 1932 numbered 509,591 as compared with 515,403 in 1931, the marriage rates being 7.9 and 8.0 respectively. While the marriage rate for 1932 is apparently slightly higher than that for 1913 (7.8) the latter year being considered a normal pre-war year, the figure shows an actual decrease if adjustment is made for the difference in the age distribution of the population in these two years. In 1932, the number of persons of marriageable age was considerably higher than in 1913. If the same proportion of men of marriageable age had married during 1932 as did in 1913, there would have been 610,000 marriages instead of the 509,591 which actually took place that year.

There were 978,161 births in 1932, as compared with 1,031,770 in 1931, which means a reduction of 53,609 in the number of births. Excepting 1917 and 1918, abnormal war years, 1932 was the first year (for which reliable statistics are available) during which the number of births was below one million. The birth rate declined from 16.0 in 1931 to 15.1 in 1932. Stillbirths decreased from 32,153 in 1931 to 29,475 in 1932, although the rate

remained practically the same, 3.1 in 1931 and 3.0 in 1932.

The number of deaths from all causes in 1932 was 697,895 and the death rate 10.8 per 1,000 population, as against 725,816 deaths and a death rate of 11.2 in 1931. Practically the entire reduction of about 28,000 in the number of deaths is accounted for by a lower mortality during the first quarter of 1932 over that of 1931, when an influenza epidemic brought the general death rate considerably above the quarterly average. Statistical data regarding the deaths from different causes in 1932 are not yet available for the whole of Germany. However, according to reports of the causes of death in the municipalities with populations of 15,000 and over, reductions of 9 per 100,000 from influenza and 13 per 100,000 from bronchitis and pneumonia were noted. There were reductions also in the death rates from the communicable diseases of childhood, tuberculosis and accidents, while suicide increased slightly in 1932 over 1931, and the diseases of middle and old age (cancer, diabetes, heart disease and apoplexy) showed somewhat greater increases. Infant mortality decreased from 83 per 1,000 live births in 1931 to 79 in 1932.—Die Bevölkerungsbewegung im Deutschen Reich im Jahre 1932. *Reichsgesundheitsblatt*, No. 27, 495-97 (July 5), 1933.

A Brief Statistical Analysis of Sanitary Conditions in Porto Rico During the Last Decade*—During the five years (1923-1927) preceding the San Felipe hurricane, Porto Rico recorded an average general death rate of 21.1 per 1,000 population, the rates in individual years showing fluctuations ranging between 19.4 and 23.4. During the following five years (1928-1932) in the course of which two hurri-

canes occurred, the average death rate was 22.0 per 1,000 population, only 0.9 higher than that for the previous five years; but the annual fluctuations were greater, varying between rates of 25.3 and 18.6. Basically the mortality conditions were similar in the 1923-1927 and the 1928-1932 periods, despite the occurrence of hurricanes in the later five years.

The San Felipe hurricane at the end of 1928 resulted in higher mortality rates for the years 1928 and 1929 followed by the low death rate of 18.6 per 1,000 population in 1930. In 1931, however, the general mortality rose to 20.4, and in 1932, the year of the San Ciprian hurricane, it increased to 22.3. The figures for the first three months of 1933 showed an average death rate of 23.0 (January 23.7; February 23.5; and March 21.9). This experience indicates that the 1933 death rate will be higher than that of the preceding year but lower than that for 1929, the year following the San Felipe hurricane.

Mortality from tuberculosis has climbed almost steadily since 1915 in which year the deaths from this cause numbered 173.3 per 100,000 population. With slight fluctuations, the rise has continued up to 1932 when a maximum rate of 293.7 was registered. The 1932 figure is the first computed under the revised classification of tuberculosis as adopted by the International Commission on Causes of Death in 1929. The wider scope of the 1929 classification partly accounts for the large increase in 1932. Estimates of the number of tuberculous persons in the Island vary between a minimum of 20,000 and a maximum of 40,000. Hospital facilities will accommodate no more than 760 patients, which means that the large majority of tuberculous persons cannot be isolated nor given necessary care. The appropriations of the health department for the control of tuberculosis are also very inadequate.

* All the figures for 1932 and the first three months of 1933 are preliminary.

A similar situation exists in regard to the control of malaria which has shown no substantial decrease since 1911. In the case of malaria, however, atmospheric conditions bring about rhythmic fluctuations in mortality in cycles of 2, 3, or 4 years. Since 1926, when the rate was 140.2, there have been annual fluctuations culminating with the rate of 203.7 in 1931. Diarrhea and enteritis has shown variable mortality since 1911 with the highest rates being recorded in 1917 (389.4), and in 1928 (314.3). During the San Ciprian hurricane (1932) the rate was 246.9 as compared with 221.6 in 1931.

Compensating factors in the general health situation of Porto Rico are those connected with typhoid fever and diphtheria, two diseases, the control of which comes well within the means of the Island's health authorities. The mortality rate from typhoid fever in 1928 was 30.8; in 1929, 14.5; in 1930, 8.5; in 1931, 6.6; and in 1932, 5.1. Similarly the diphtheria mortality was 6.2 in 1928; 6.0 in 1929; 3.4 in 1930; 3.9 in 1931; and 2.9 in 1932. In both of these diseases the reduction in mortality has been not only constant but very marked, amounting to 83.4 per cent for typhoid fever during the five year period and 53.2 per cent for diphtheria during the same period. The infant mortality has decreased rather consistently since 1911 when the rate was 196 per 1,000 live births; in 1930, the minimum of 126 was reached. This was followed by 130 in 1931 and 132 in 1932.—*Sanitary and Demographic Bulletin of Puerto Rico*. English Supplement. Government of Puerto Rico Department of Health. Year II (May 15), 1933.

Deaths from External Violence in Canada, 1932—According to a report issued by the Dominion Bureau of Statistics the number of deaths in Canada from external violence during

the year 1932 (preliminary figures) was 6,611 as compared with 7,172 in 1931 and 7,478 in 1930. The rate per 100,000 population was 63 in 1932 as against 69 in 1931 and 73 in 1930. The death rate from external violence for 1930 was the highest recorded in Canada during the period 1926–1932. The 1932 rate shows a fall of 10 per 100,000 from this peak and 6 per 100,000 from the rate for 1931.

Suicides numbered 1,020 in 1932, as compared with 1,004 in 1931 and 1,010 in 1930. All three of these years showed a marked increase over 1929 when suicides numbered 835. The death rate from suicide was 9.7 in 1932 and 1931, 9.9 in 1930 and 8.3 in 1929.

There were 157 homicides in 1932 giving a rate of 1.5 per 100,000. These figures compared with 172 deaths and a rate of 1.7 in 1931 and 214 deaths and a rate of 2.1 in 1930. The 1930 homicide rate was the highest in the period 1926–1932. In 1926 the rate was 1.3.

The number of deaths resulting from accidents in 1932 was 5,434 and the rate 52 per 100,000, as compared with 5,996 deaths in 1931 giving a rate of 58 and 6,254 deaths in 1930 giving a rate of 61. The 1932 rate was the lowest during the period 1926–1932.

Drownings in 1932, exclusive of those occurring in land or air transportation, numbered 980 or 18 per cent of the total of fatal accidents. Land transportation accounted for 1,586 deaths or 29 per cent of the total. Of these, deaths in automobile accidents numbered 1,111, or 20 per cent of all accidental deaths. Excluding those cases where an automobile was involved, there were 242 deaths in railroad accidents and 44 in street-car accidents. Eleven persons were killed during the year in aeroplane and balloon accidents.—Mimeograph release sheet. Canada Dominion Bureau of Statistics, June 28, 1933.

PUBLIC HEALTH ENGINEERING

Jail Sentence for Maintaining Cross Connections—For several years the Water Department of the City of Los Angeles has waged an energetic campaign against the practice of making cross connections between foreign sources of water supply and the city distributing system. This practice is forbidden by city ordinance No. 66498. It was discovered recently that certain fish companies in the harbor district maintained such cross connections between the city system and their own system, which provided water pumped from the bay. On December 7, 1932, complaints were shown by officials of the water department against four fish companies which maintained these cross connections. In the hearing which followed, the water department traced its vigilance in protecting its own supply and showed how its efforts were nullified through the maintenance of these cross connections. The court imposed jail sentences of fifteen days upon each of the defendants without the alternative of a fine. Subsequently, the sentences were suspended with warnings that future violations would result in more severe sentences not subject to suspension.—Anon., *Weekly Bull.*, California Department of Public Health, XI, 49:195 (Jan. 7), 1933. (From *Pub. H. Eng. Abstr.*, XIII, W, 28, 3-4-33.)

Why Not Make Garbage Collection and Disposal Self-Sustaining?

—This brief article discusses the feasibility of financing refuse collection and disposal by a service charge or a special tax against the householder, rather than from the general tax levy. Many communities at present make a uniform charge per dwelling for the collection and disposal of refuse. One

possible method is to make a charge according to weight of refuse collected but this is complicated by the necessity of maintaining records and of weighing the refuse. Another method is to have a schedule of rates based upon the size and type of buildings, and still another possible method is to have a schedule of rates based upon the assessed valuation of property. Paying for the collection and disposal of refuse in this way would permit municipalities to receive loans from the Reconstruction Finance Corporation for refuse disposal plants, such as incinerators, on a self-liquidating basis.—Harrison P. Eddy, *Am. City*, XLVII, 4:52-53 (Oct.), 1932. (From *Pub. H. Eng. Abstr.*, XIII, GR, 4, 3-4-33.)

The First Completely Air Conditioned Theatre in Spokane—A feature of the system of air conditioning used in the Spokane theatre is the location of the equipment above ground, in a manner to make it visible to passers-by. This design eliminated expensive basement excavation (Spokane is built on solid rock) and serves as an excellent means of advertising the system. Another feature of economic consideration is the use of a compound air washer, the first using city water and the second refrigerated water. This type of washing system was installed in order to take advantage of the low maximum temperature of the city water in the summer months (52° F.), thus requiring a rather small refrigerating system. Other features of this system are provisions for exhausting the air in the projection room and the rest rooms, the exhausted air being delivered outdoors. The capacity of the exhaust fans is less than the air supplied for

ventilating purposes, thus keeping the theatre under a slight pressure and preventing the infiltration of dust. The air conditioning plant is designed to maintain in the theatre proper a dry bulb temperature of 80° F. with a relative humidity of 44 per cent when the outside dry bulb temperature does not exceed 95° F. and a wet bulb temperature of 75° F. These conditions are maintained at a capacity of 2,200 occupants.—R. H. Beck, *Heating & Vent.*, XXX, 1:31-33 (Jan.), 1933. (From *Pub. H. Eng. Abstr.*, XIII, AC, 3, 3-11-33.)

Ammonia Chlorine Treatment Used on East Providence, R. I., Water Supply—The water, from Ten Mile River, having a drainage area of 54 square miles, containing some swampy areas, has an inferior bacterial quality and a wide variation in color. Chloramine treatment was started in March, 1931. This permitted the carrying of a much higher residual chlorine, reduced aftergrowths in the clear well resulting in very soft instead of hard growths on the pipes in the clear well. Also the filters remain much sweeter and cleaner, although showing no increase in length of run nor reduction in wash water.

The fact that the ammonia chlorine treatment is slower to act was not important even though the nearest consumer is within 400 ft. of the filter plant; samples of water taken twenty minutes after the addition of chlorine, the time estimated as required to reach the nearest consumer, showed no difference whether ammonia was used or not, when tested bacteriologically. Other tests showed that the ortho-tolidine test could be relied upon, but must be interpreted differently and more cautiously. The ortho-toluidine should be added and the reading made within about 20 minutes of the collection of the sample, but in an extreme case in

December the sample did not develop its full color until 45 minutes.—James V. Turner, *W. W. Eng.*, LXXXVI, 5:208-209 (Mar. 8), 1933. (From *Pub. H. Eng. Abstr.*, XIII, W, 49, 4-29-33.)

Institutional Sewage and Sewage Flow Characteristics—The results of studies on characteristics of institutional sewage flows and raw sewage composition are given with reference to the effect of these factors on plant design and operation. Average daily flows varied from 99 to 266 g.p.c. and showed some correlation with type of institution. The lowest ratio of maximum to average rate of flow was 1.5. Contrary to the general impression, institutional sewages were in all cases from two to three times stronger than strictly domestic sewages. The average 5-day B.O.D. on the basis of 100 gal. per capita flow was 472 p.p.m. Per capita 20-day oxygen demand varied from 208 to 286 grams per day. Both settleable and non-settleable solids were generally higher than domestic sewage. In some cases the grease content of raw sewage was very high. Sludges were quite similar to domestic sludge.

High flow rates and stronger sewages vary with different institutions and their topographical situations. Before designing an institution sewage treatment plant a careful study of rate of flow should be made and the sewage should be analyzed.—G. M. Ridenour and I. O. Lacy, *Sewage Works J.*, IV, 6:1046-53 (Nov.), 1932. (From *Pub. H. Eng. Abstr.*, XIII, S, 31, 5-6-33.)

The Electrical Precipitation of Sewage—A description of the electrical process of sewage treatment first tried out on a plant scale in 1888-1889 by Webster at the South Metropolitan outfall at Crossness. This article is principally about the recent work done with this process by the Niersverband,

one of the youngest German river authorities. The process depends upon the passage of the sewage between metal electrodes, the metal going into solution in the form of ions at anode, and then being rapidly converted into the soluble hydroxide resulting finally in the flocculation of the polluting matter in the sewage, which is then settled out. The permanganate absorption of the sewage has been reduced 45 to 50 per cent and the biochemical oxygen demand 60 per cent by this treatment. Compressed air is used to obtain mixture of the tank contents. It is stated that the energy obtainable from the gas produced in digestion of the sludge is sufficient to meet the electrical and air requirements. Iron is said to be the best electrode material, and that it requires about 50 gm. of iron per c.m. of sewage treated. An experimental plant working on the electrical system was constructed at the Rheydt sewage works and the results obtained there confirmed laboratory results.—*Surveyor*, LXXXIII, 2139:61 (Jan 20), 1933. (From *Pub. H. Eng. Abstr.*, XIII, S, 31, 5-6-33.)

An Unusual Sewage Treatment Plant—Sewage from London, Ontario, is disposed of in four separate treatment plants. This article describes the new West End plant designed to treat the maximum flow of 6,000,000 gallons per day. This plant consists of the following units: a large grease trap; grit chamber, fitted with one-inch diameter perforated pipes for admission of either air, or water at intervals to wash grit free of entrained organic matter; a Hankin paddlewheel type, screen with $\frac{1}{2}$ inch clear openings revolved by the sewage flow; a Hankin fine screen; 24 aeration tanks, which provide $\frac{1}{8}$ hour's detention. Two compressors of 500 cubic feet and one compressor of 1,500 cubic feet per minute of free air, compressed to 10 lbs. pressure, are used to force air through three types of diffusers,

namely—filtros plates, activated sludge, ltd. plates, and $\frac{1}{4}$ inch diameter perforated pipes. Air piping is arranged to permit flexibility of operation. There are 2 50-ft. square tanks fitted with Hankin-Fidder scrapers of the twin spiral type. The detention period is one hour and 12 minutes.

The unusual feature of this plant is the discharge of excess activated sludge into the raw sewage whereby the activated sludge adheres to the sewage solids and is removed by the fine screens. The solids so removed are incinerated in a small incinerator. Auxiliary fuel is only required to start the incinerator, which has a capacity of 10 tons of wet screenings per day. Before the screenings are incinerated they are pressed in a home made equipment. The moisture content of the pressed screenings and activated sludge is 87 per cent. The total cost of the plant is estimated to be \$190,000.—W. M. Veitch, *Am. City*, XLVIII, 2:54-56 (Feb.), 1933. (From *Pub. H. Eng. Abstr.*, XIII, S, 24, 4-1-33.)

The Effect of Pasteurization Upon *Brucella Melitensis* Var. Suis—Pasteurizing tests using a standard pasteurizing outfit were undertaken to determine whether the porcine strain of the *Brucella* organism was destroyed during the process. Checks on the efficiency of pasteurization were made with milk inoculated with the bovine strain of the organism.

It was found that a temperature of 62 to 63° C. (143.6 to 145.4° F.) for 3 minutes was sufficient to destroy both types of the organism. This shows that the usual pasteurizing procedure when correctly operated provides an ample factor of safety. However, with the lid of the pasteurizer open a much longer exposure was necessary, and the results were irregular and uncertain. The viable organisms were recovered from the foam of such milk even after

30 min. When an ordinary faucet outlet was used on the pasteurizer live organisms were isolated from the outlet after 30 min. pasteurization, while when the outlet was closed by a stopper on the inside no living organisms remained

after 3 min. exposure.—C. Murray, S. H. McNutt, and P. Purwin, *J. Dairy Sci.*, XV, 1:6-13 (Jan.), 1932. *Experiment Station Record*, U. S. Department of Agriculture, LXVII, 6:734 (Dec.), 1932.

INDUSTRIAL HYGIENE

Chemical Haematuria from Handling 5-Chloro-Ortho-Toluidine— Nine cases of haematuria in connection with the purification of 5-Chloro-Ortho-Toluidine and also its hydrochloride derivatives are discussed. These cases occurred in an epidemic extending over a period of four months. The toxic substance and its mode of entry is not definitely known. In the haematuria cases the bladder was chiefly affected, although the kidney was involved to a slight extent. Cyanosis was present, with strangury and frequent micturition, with exfoliation of the bladder epithelium.

The processes followed in the purification of these aniline products are also described.—Arch. N. Currie, *J. Indust. Hyg.*, 15:205-213 (July), 1933.

L. G.

An Outbreak of Dermatitis in Cotton Mills Due to Varnish— Cases of dermatitis occurring in a textile plant were investigated. The dermatitis was confined to parts of the workers' arms that rubbed against heddle frames which were coated with a particular varnish. Nineteen out of 32 workers exposed to this varnish contracted dermatitis. By means of patch tests the cause was finally traced to two ingredients of the varnish, cumaron resin and ceresin. Varying individual susceptibilities were demonstrated.

The addition of normal saline solution to the materials used in the patch

tests to simulate action of perspiration added to the irritating action of these substances on susceptibles. — Louis Schwartz and Charles L. Pool, *J. Indust. Hyg.*, 15:214-225 (July), 1933.

L. G.

A Case of Carbon Monoxide Poisoning From an Oil Stove— The case history and discussion of a suspected case of carbon monoxide poisoning from a smoking oil stove are presented. The peculiar features of the case were: an unusually long period (3 days) of coma with subsequent recovery; several canary birds and a dog in the room and adjoining room were unaffected; and failure to demonstrate presence of carbon monoxide haemoglobin on spectroscopic examination (later discovered that a faulty technic had been employed).

The importance of a properly conducted blood examination after a case of carbon monoxide poisoning as a means of diagnosis and for medico-legal consideration is stressed. Several tests for the detection of carbon monoxide haemoglobin in blood are suggested.—Lewellys F. Barker, *J. Indust. Hyg.*, 15:238-241 (July), 1933.

L. G.

The Relation of Carcinogenicity of Mineral Oils to Certain Physical and Chemical Characteristics of These Oils— The various properties of oil in relation to their carcinogenicity were studied. The refractivity of an

oil appeared to be a good indication of its field of origin as well as a probable indication of its carcinogenicity. The iodine value of an oil also seems to afford an index of its toxicity provided it has not been treated. Oil from 11 different fields were studied and out of these the Pennsylvania oil alone failed to follow the general index of carcinogenicity as determined by the above methods.

The permanganate oxidation values give varying results and are therefore not considered to be of any value in estimating the toxicity of oils.—R. Lyth, *J. Indust. Hyg.*, 15:226-237. L. G.

Sand and Metallic Abrasive Blasting as an Industrial Health Hazard

—This is a study of the dust hazard in air pressure abrasive blasting operations. A preliminary survey and analysis of the equipment found in 44 plants in 8 states was made, followed by a detailed study of 28 shops located in 4 States. The survey showed that sand was used as an abrasive in 64 per cent of the cases, metal (steel grit and shot) in 34 per cent, and a mixture of sand and metal in 2 per cent of the cases. A description of the four types of generally used air pressure abrasive blasting equipment is presented.

The detailed study consisted of a general plant survey, dust sampling with the Greenburg-Smith impinger, determination of particle size and mineralogical composition and ventilation observations. The efficiency of the positive-air pressure helmet with various quantities of air flow was also determined.

The results showed the following: (1) The particle-size of practically all the dust was less than 5 microns, modal size between 1-1.5 microns, and only 1 per cent was less than 0.5 microns in size. (2) When sand alone was used the quartz content varied from 42-98 per cent; quartz content of air with sand and metal mixtures as abrasive

averaged 44 per cent; and quartz content 3 per cent with metal abrasives. (3) The dust concentration (in millions of particles per cubic foot of air) was as follows: Sand blasting rooms (exposure under helmet with non-positive air pressure) 241; sand blasting room (exposure under helmets with positive pressure) 4.7; barrels, 29; tables, 25; cabinets, 3; automatics, 24. (4) Dust hazard is present even in well designed and adequately ventilated rooms with properly designed and maintained equipment when abrasive blasting is in progress. This indicates the necessity for special protection of the worker. (5) The provision of a positive supply of 6 cubic feet of dust-free air per minute to the helmet will protect the worker under actual operating conditions in an abrasive blasting room.—J. J. Bloomfield and Leonard Greenburg, *J. Indust. Hyg.*, 15:184-204 (July), 1933. L. G.

Pulmonary Asbestosis: Its Clinical, Radiological and Pathological Features, and Associated Risk of Tuberculosis Infection—The clinical, radiological, and pathological feature of asbestosis are excellently presented. Symptoms of asbestosis generally appear after several years of exposure to this dust—usually after 5-15 years. The average length of employment in fatal cases is about one-half that in silicosis. The symptoms of asbestosis are dyspnoea which is usually out of all proportion to the clinical findings, cough, expectoration, anorexia, cyanosis, emaciation, finger clubbing, and asbestos corns. These symptoms are aggravated during the winter season. Limited chest expansion, impaired percussion note, fine, dry crackling râles and pleural friction sounds are some of the common clinical findings.

The radiological studies are characterized by a fine, diffuse pulmonary fibrosis commencing at the base of the

lungs. The author is of the opinion that a radioscopic examination of the chest followed by a satisfactory radiograph affords the most reliable single evidence in establishing a diagnosis of the state and extent of asbestosis cases.

The characteristic golden-yellow asbestosis bodies found in the sputum and fibrosed lungs of the asbestos workers are described. It is interesting to note the persistency of these asbestosis bodies in the sputum; a patient exposed to asbestos dust for one year showed the presence of these bodies in the sputum 14 years later.

Pulmonary asbestosis, once established, is a progressive disease with a bad prognosis. Until recently tuberculosis complication in asbestosis was thought to be rare but the experience of the author casts some suspicion on this belief. The recognition of the existence of a tuberculosis risk in asbestosis is important when considering preventive measures for this occupational disease.—Philip Ellman, *J. Indust. Hyg.*, 15: 165-183 (July), 1933.

Filtered Air Relieves Hay Fever—

This is a study on the removal of symptom-producing substances in hay-fever and pollen asthmatics by the filtration of air. The process of filtration differs somewhat from dust removal in that it is necessary to remove all possible allergic material in order to relieve highly sensitized individuals.

The efficiency of the filters as determined by (1) exposing vaselined slides to the air before and after filtration and (2) counting pollen grains on vaselined slides exposed to outdoor and indoor air, was from 96-98 per cent. The authors believe that a high efficiency of removal may be obtained by using large filter areas with low air resistance and low velocity of air flow.

Clinical observations were made on hay fever and pollen asthma patients who were admitted to the filtered air

wards in the evening for a period of 12-16 hours and then sent out during the day. The study showed that symptoms of hay fever would disappear in 80 per cent of the cases after an exposure of 3 hours or less to filtered air. The disappearance of symptoms was not indicative of cure since there were recurrences of symptoms on exposure to pollen-laden air. The filtered-air treatment, however, is of value since it increases the personal efficiency of the patients in giving them an increased amount of restful sleep. Pollen asthma patients respond more slowly to treatment and no appreciable relief could be obtained unless the patients were exposed to the filtered air continuously.—William W. Welker, B. Z. Rappaport, and Tell Nelson, *Heating, Piping & Air Conditioning*, 5:348-350 (July), 1933.

Industrial Diseases of the Skin—

The chief industrial diseases of the skin are: Anthrax, the most dramatic and perhaps the least common; cancer; and trade dermatitis. Not less than 15,000 cases of dermatitis are certified by factory surgeons every year. Anthrax, chromium compounds, dermatitis in the food industry (bakers, confectioners, and jam makers) are discussed briefly.

Dr. N. Howard Mummery, in discussion, stated that the dermatoses seen in industry, with a few exceptions, were not peculiar to the occupations involved, nor were they more common among industrial employees than among the rest of the community. True industrial dermatitis was uncommon and many of the substances handled were the same as used at home. The warm months, new workers, the state of the skin, were the important factors. "A girl might work for years at a job without any skin trouble, and then become highly sensitive to the irritant; after some months she might again become immune to it."—H.

Haldin-Davis (excerpts from address), *Lancet*, 5729:1288-1289 (June 17), 1933.

Effects of Dust Upon the Respiratory System—This is the proceedings of a special conference held in Chicago, Nov. 16-17, 1932, under the auspices of the Industrial Commission of Wisconsin, whose Chairman, Fred M. Wilcox, opened the conference. The first address was by Dr. Leroy U. Gardner, Director of Saranac Laboratory for the Study of Tuberculosis, who discussed, for the lungs, the anatomy, the treatment of inhaled foreign bodies, pathology, tuberculosis of various types, and pneumonia. This address with intercurrent discussions by those present covers approximately the first 50 pages of the proceedings.

The second address was by Dr. W. Irving Clark, Medical Director of the Norton Company, Worcester, Mass., and concerns the composition of abrasive wheels, with the showing of chest X-ray films after various years of exposure (pp. 50-70, including discussions).

Dr. Gardner then resumed his address, in which he summarized and amplified his previous remarks, accompanied with a series of 39 slides.

The third address was by Donald E. Cummings, Assistant Director of the Saranac Laboratory, who took up the chemical and physical properties of certain dusts, followed by a discussion of the silicosis hazard in the lead and zinc mines of Picher, Okla. Discussions of Mr. Cummings' and Dr. Gardner's addresses continue to page 124. Next, Dr. H. S. Willis, Pathologist of the Maybury Sanatorium, Detroit, discussed the pathogenesis of silicosis and its relation to tuberculosis, with results of animal exposures, exposure to vegetable and mold dusts, and roentgenological evidences followed by a brief general discussion).

J. J. Bloomfield, Sanitary Engineer, U. S. Public Health Service, followed with an address on the nature of dusts, and especially of silicious dusts, the size of dust particles, dust concentration, and dust suppression—with bibliography (pp. 136-166).

The concluding address was by Dr. Albert E. Russell, Surgeon, U. S. Public Health Service and U. S. Bureau of Mines, who reported upon the study of the dusty trades, beginning with the cement industry in 1924, and accompanied his discussion with X-ray slides from different industries showing various reactions to dust (address with discussion, pp. 167-207).

The Report concludes with brief biographic sketches of the six principal speakers and a list of the 67 persons in attendance.—Wisconsin Indust. Comm., Madison, 215 pp. (Feb.), 1933.

E. R. H.

Arsenic Poisoning in a Manganese Factory—Dr. Salmon and Dr. Planque (*Ann. d'hyg. pub. indust. et sociale*, April, 1933) have lately described an outbreak of arsenic poisoning in a factory which, in December, 1929, began to crush and dry salts of manganese. In October, 1932, some of the employees were found to be suffering from such symptoms as pain in various parts of the body, difficulty in walking (particularly downstairs), stuttered speech, and mask face. The extensors of the legs were slightly atrophied and a steppage gait present. In none of four cases were there cutaneous manifestations, a positive Wassermann, cyanosis of the extremities, or hyperkeratosis of the palms of the hands or soles of the feet. In diagnosis, lethargic encephalitis and disseminated sclerosis had to be considered.

Inspection of the factory showed the workers looked like "blackamoors." so thick was the manganese dust on them. They were all indoor workers. How-

ever, one of the most exposed to the dust had shown no signs of poisoning. Also those who worked outdoors were free of symptoms. "An analysis of the powder handled in the factory showed it to contain over 81 per cent of the oxides of manganese, and over 9 per cent of silica. It also contained

0.013 per cent of arsenic." (Surely these cases would be called *manganese poisoning* in this country, where several similar reports had been made since the first one by Casamajor in 1913.)—(*Abstractor's comment.*) *Lancet* (Notes, Etc.). 5729:1325 (June 17), 1933.

FOOD AND NUTRITION

The Character of the Dermatitis-Producing Factor in Dietary Egg White as Shown by Certain Chemical Treatments—This represents an extension of work previously reported (*Abstract, A.J.P.H.*, Vol. 21, May and Sept., 1931), in an effort to determine the nature of the toxicity of Chinese dried egg whites. Rations employing respectively 66, 40, 30 and 20 per cent, on a dry basis, of egg white, were given to rats. The pellagra-like symptoms in these young rats were first produced by a basal egg white ration with 66 per cent of egg white. Substitutions or additions to the diet were then made to determine the effect of various methods of treatment of the egg white. Results were measured by the degree of severity of the pellagra-like syndrome. Definite toxic symptoms followed the ingestion of Chinese whites, raw and dried, fresh whites, raw and dried, Chinese whites precipitated by alcohol and dried. In the latter case, neither treatment with alcohol for 35 days nor dialysis of the alcohol precipitate for 50 hours before drying lessened the toxic symptoms. No beneficial effect was secured from Chinese dried whites either treated with nitrous oxide or when treated with formaldehyde. When 1.6 c.c. normal hydrochloric acid per gram was added to the Chinese whites incubated at 37° for three days and dried, the animals showed a prompt response with a disappearance of the pellagra-like condi-

tion. The same results were secured with this percentage after neutralizing and drying. The addition of 1 per cent normal hydrochloric acid per gram and incubation did not relieve the toxic condition of the egg white nor did the addition of 1.6 c.c. normal acetic acid with similar incubation. Satisfactory curative results were secured with fresh egg whites heated to 80° for either 5 or 20 minutes. The toxic effects were apparently not due to denaturation as evidenced by the toxicity of egg white after it is denatured with alcohol. There is an indication that the detoxification involves hydrolysis. The same satisfactory result was secured with 1.6 c.c. normal hydrochloric acid per gram, either with or without peptic digestion. —Helen T. Parsons and Eunice Kelly. *J. Biol. Chem.* 100:645 (May), 1933.

Effect of Sunshine Through Window Glass and Fresh Air on Resistance to Infection—The effective narrow band of ultra-violet solar rays which prevent or cure rickets does not penetrate common window glass. Little definite information exists as to the effect of either the visible or infra-red rays on the growth of the animal organism. Several investigators have shown the effect of clouds, dust and smoke on the ultra-violet rays, particularly during the winter months. The observation is made that the same influence affects the intensities of the

visible and infra-red rays, and the therapeutic value of sunshine with fresh air in the treatment of tuberculosis is cited.

In these experiments, young rats on a normal diet without any concentration of vitamin D, such as cod liver oil, were kept away from sunshine. Once a week, litters of these rats, from 25 to 27 days old, were divided into 5 groups and 3 of the groups placed on a modified rachitogenic diet. For 4 weeks one group was given direct sun bath under window glass from 11:00 A.M. to 1:00 P.M. The total sunshine received in the experiment was from 25 to 35 hours. Another group of rats was exposed to fresh air only, but all other conditions were the same. A third group was kept inside. At the end of 4 weeks, no great differences in weight were shown in the three lots. At this time two representative rats from each group were used for the determination of inorganic phosphorus in the blood and the percentage of bone ash in the long bones. Very little difference is shown between the three groups. Rats were then infected with a culture of "rat typhoid" a strain of *Salmonella enteritidis*, isolated from the infected middle ear of a white rat. Four weeks after infection, experiments were terminated with the result that the rats given fresh air and sunshine through common window glass survived in greater numbers than the group kept inside. The rats kept in fresh air survived better than those kept inside except in one instance. Conclusion, therefore, is drawn that both fresh air and sunshine through glass increase resistance. In the case of rats which received a modified rachitogenic diet fortified with additional vitamin D, the rats exposed to direct sunshine through glass withstood infection better than the inside controls. Fifty-seven per cent of the rachitic rats under common window glass survived, against 32 per cent kept

inside. With the vitamin D, 75 per cent of those exposed under glass survived, against 61 per cent kept inside. The vitamin D furthermore increased the ability of the rats to withstand infection.

The authors point to the fact that on a rachitogenic diet the increased resistance was not responsible for the improvement of the rickets, since the sunshine which penetrates common window glass is without antirachitic effect. They conclude with the following:

The vital radiations from the sun should not be limited to the narrow band in the short ultra-violet region, which is antirachitic. The foregoing results show definitely that rays longer than those that are necessary to prevent or cure rickets have a marked effect on the animal organism, as evidenced by a decided increase in resistance to infection.—

John R. Ross, Elizabeth Chant Robertson, and Frederick F. Tisdall, *Am. J. Dis. Child.* 45:81 (Jan.), 1933.

Food Poisoning Due to Staphylococci—An outbreak of gastroenteritis occurred among women students of a southern educational institution involving 150 marked cases, 75 of which were severe. A number of other victims suffered less severely. Conclusive epidemiologic evidence incriminated chocolate eclairs as the vehicle carrying the causative agent. Of those who ate eclairs, 60 or 70 per cent were affected. The onset of symptoms was within two or three hours following ingestion. The custard filler for the eclairs was prepared at the bakery in the morning and the eclairs were delivered at 11:00 A.M. There were several batches of eclairs which may help to explain why more of those who ate eclairs were not made ill. The symptoms were marked by nausea, salivation, abdominal pain, vomiting, extreme prostration, profuse diarrheal attacks and chills. Bacteriological examinations of the custard from the

eclairs and of the pastry disclosed the presence of numerous yellow staphylococci and no organisms resembling the *Salmonella* group. Ten cubic centimeter quantities of bacteria-free filtrates prepared from cultures of the cocci were fed to each of eight human volunteers in 200 c.c. of pasteurized milk. As controls, four students were given similar amounts of sterile broth of the same batch used for growing the organisms. Of those receiving the filtrate all were ill except one: she was slightly nauseated and felt weak. None of the controls was affected. All symptoms, which appeared in from 1 $\frac{3}{4}$ hours to 3 hours, were similar to those exhibited by the women students who were sick following the consumption of eclairs. Examination of all ingredients used in preparing the eclairs and careful investigation of conditions at the bakery failed to disclose the source of the staphylococci. Experiment showed that the cocci isolated from the eclairs would be destroyed at the temperature and during the time of cooking the custard filling. It is stated that pastries, custard fillers and the like should be well protected against contamination in preparation and storage. Custard fillers should be refrigerated. After baking, cakes and pastries should be covered or placed in specially constructed cases and not left in the open. These precautions could well apply to the storage and handling, following delivery, especially in institutions where a large kitchen force is employed.—Ralph McBurney, *J.A.M.A.* 100:1999 (June 24), 1933.

Studies on the Physiological Action of Glycerol on the Animal Organism—The authors have summarized their work as follows: In studies of replacement of carbohydrate by glycerol in the diet of rats (40 weeks) to a point where glycerol consti-

tuted 41 per cent by weight of the total food intake, and in the diet of dogs (50 weeks) until it amounted to 35 per cent of the intake, normal growth occurred. Reproduction in rats was unaffected. Addition of glycerol to a rat diet qualitatively adequate but quantitatively just sufficient for maintenance of body weight caused a resumption of normal growth. Addition of 110 grams of glycerol per day (50 days) to an adequate diet in man produced a slight tendency toward increased body weight.

Ingestion by growing dogs of 9 grams of glycerol per kilogram per day for nearly a year did not change the red blood cell count. Ingestion by man of 110 grams of glycerol per day for 50 days did not affect the red or white cell counts or the hemoglobin content of the blood. In neither man nor dogs was albuminuria or hemogloburia produced from glycerol taken orally, although both of these phenomena were produced in dogs upon parenteral administration. Glycerol per os in relatively large quantities exerts a diuretic action in dogs and rats, but in the quantities fed to man it lacked this effect. The body temperature of man and dogs was unaffected by glycerol ingestion. No adverse subjective effects in man and no changes in the general appearance and behavior of rats and dogs throughout the observation periods, resulted from glycerol ingestion in the quantities used. In man the basal metabolism and uric acid excretion were not significantly affected. Activity of the large intestine of man as regards daily number and consistency of stools, was unaffected by the quantities of glycerol fed. No gross or microscopic pathology was detected in rats and dogs reared (for nearly a year) on diets of high glycerol content.—Victor Johnson, A. J. Carlson, and Adelaide Johnson, *Am. J. Physiol.* 103: 517 (Mar. 1), 1933.

CHILD HYGIENE

THE TUBERCULIN SKIN TEST FROM THE SCHOOL PHYSICIAN'S STANDPOINT

L. W. CHILDS, M.D.

*Supervisor, Health Service, Bureau of Physical Welfare,
Board of Education, Cleveland, Ohio*

DURING 1931, 769 Clevelanders succumbed to pulmonary tuberculosis.

86 of these cases were reported three months before death,
140 only one month before death,
131 less than one month, and,
79 at or after death.

A total of 436 cases were reported only three months or less before death. The amount of damage resulting from the dissemination of the tubercle bacilli cannot be calculated.

Too long has the medical fraternity placed its chief reliance on the use of the stethoscope. Too long have we been concerned only with the familiar type of the disease. The hidden and dormant type with only an involvement of the lymph nodes with possible minor changes in the adjacent lung tissue, has until of late been unrecognized. For a number of years we have known of this childhood type of tuberculosis and have sought to recognize it by means of a chest examination of each elementary school child. The stethoscope, aside from cardiac ailments, has revealed little of value. The time and the effort of a trained staff of physicians in the discovery of pulmonary lesions did not produce results commensurate with the cost of the service.

The pupils of our open air classes were mainly selected from a group of underweight children, since it had always been assumed that the poor

underweight was in the pre-tuberculous stage and must be provided with a hood and coat and placed in a room that had escaped the notice of the mechanical ventilation expert. This arrangement provided rest periods, fresh air and food for these underweights who were often tuberculosis contacts. Upon the whole it was questionable whether our open air classes (22 in number) produced results which justified the extra outlay of money necessitated. In order to determine whether the 50 per cent extra expense per pupil was really justified in terms of health, a competent member of our Health Service Staff, Dr. Joyce I. Hartman, made a survey of our open air classes during the school year 1930-1931 and submitted the following report:

The open air school rooms were instituted in Cleveland 20 years ago primarily for tuberculous children whose condition was not regarded as serious enough to warrant hospitalization or "preventorium" care. The beneficial effects of special rooms, extra rest, and extra food have always been recognized in the care of such individuals. Since the cost of maintaining these special rooms is high (at least 50 per cent additional per pupil) it has been important to select the proper children. The selection of these children has been a problem. Until recently they have been selected upon the following criteria: (1) Malnutrition, (2) symptoms such as cough, (3) history of contact, (4) opinions of school physicians, nurses, and teachers. It has been recognized that such methods were grossly inaccurate. During the school year of 1930-1931 it was decided to make a survey

of the pupils in the open air rooms to find out what percentage, selected upon the above basis, have or have had a tuberculous infection as is shown by the most reliable method available, the intracutaneous tuberculin test. These tests were made with dilutions of old tuberculin (human) and phenolized saline controls. These tests were done upon the forearm, and in 95 per cent, 1 in 1,000 solution of tuberculin was used. Where there was any evidence of possible increased sensitivity such as scars on the cornea due to old phlyctenular ulcers, history or evidence of asthma and other allergic diseases, a dose of 1 in 10,000 solution was used. The tests were read in 48 hours. Only one test was made on each individual and it is admitted that probably in a few cases the reaction appeared negative, which with the repetition of a greater dosage might have been positive. No severe generalized reactions occurred.

One hundred and seventy-eight boys and 310 girls, a total of 488 pupils in 22 open air rooms in seven different schools were tested. An average of only 35 per cent was found positive. There was a 2 per cent sex difference, the boys being higher. The age range of these children was from 7 to 12 years.

In one school where 100 pupils were tested, only 16 per cent were found positive. This school is located in an Italian section. The highest percentage was found in a Negro school where 71 pupils were tested, 52 per cent being found positive.

Eighty-five per cent of the open air pupils were underweight (8 per cent or more according to the height-weight charts). The percentage of malnutrition was the same in the schools where the percentage of positive tuberculin tests was low—16 to 20 per cent; and where it was high, 52 per cent. Only 35 per cent of the underweight children in the open air rooms had positive tuberculin tests.

These facts verify what we thought was true, that pupils had been placed in open air rooms chiefly on the basis of malnutrition, and corroborates our opinion, and that of others, that tuberculosis is not a common cause of malnutrition in the pre-teen age.

Sixteen per cent of the children tested came from families where there was some record of tuberculosis in another member of the family. Seventy-five per cent of these had positive tuberculin tests.

At present, tests are being made in the regular rooms to ascertain the proper location of open air rooms and to replace the 65 per cent of negative reactors now in open air rooms. Plans are being made to obtain roentgenograms of the chests of all positive reactors as this offers the best if not the only

means of ascertaining the activity and extent of the disease.

CONCLUSION

(1) The work has demonstrated the practicability of the intracutaneous tuberculin test in public school health work.

(2) The intracutaneous tuberculin tests as done in the open air schools of Cleveland show, (a) that tuberculosis is not concerned in large percentage (65 per cent) of malnourished children of the pre-teen age. (b) That a large percentage (75 per cent) of children from tuberculous families reported by the City Health Department have or have had a tuberculous infection.

(3) It is our opinion that the intracutaneous tuberculin tests supplemented with roentgenographic studies of the positive reactors is probably the only satisfactory method for selecting pupils for open air class rooms.

I am not taking the attitude that open air rooms should be available only to the delicate child showing a positive cutaneous test. There are other pupils among which are certain cardiacs in need of rest periods; asthmatics in need of oxygen; and grave cases of malnutrition in need of food, rest, and a knowledge of simple health rules. In general, however, open air rooms should be used for delicate pupils with the childhood type of tuberculosis.

The early detection of this infection rests with the needle and not with the stethoscope. Dispensaries are provided in a majority of school buildings, but they are not the quiet places that one could wish for in the careful auscultation of the lungs of school children. Such an examination is unnecessary in the negative reactors, or about 80 per cent of elementary school children, and 40 per cent of the pupils of high school age. Thus the school physician is relieved of a vast amount of chest auscultation carried out under difficult conditions and as far as the detection of a tuberculous infection is concerned, with meager results.

But some one enquires; is not this method of ferreting out open cases of

pulmonary tuberculosis among the parents through the detection of recent infection in their children exceedingly costly? After all, are not the results so meager that it is really better to conserve the tax-payer's dollar and, if need be, to spend the same for wholesome food which in turn will tend to prevent tuberculosis?

If it is good policy for the public to spend public funds liberally in the detection and the subsequent trial and incarceration of a criminal, why will not society profit to an equal degree by the detection and the subsequent examination and the safeguarding of the public from an open case of pulmonary tuberculosis. Both are a menace to the public. Both may require confinement. The one in a prison, the other in a sanatorium. Both bring tragedy to the home.

Preventive treatment would have saved either. The criminal could have been saved by the psychiatrist had he been discovered at an early date and a proper training instituted. The positive reactor to the tuberculin test could have been taught to know his own limitations. Health education in the school curriculum would have taught him health habits which would by their exercise, have prevented the extreme tragedy.

If then, it is good public policy to safeguard a child with criminal tendencies by educational procedures, it is likewise good public policy to safeguard a child with tuberculous tendency, to teach him to know his limitations and the simple laws of health the following of which will enable him to avert the supreme tragedy.

Upon the whole, if it is a good procedure to employ a Sherlock Holmes to ferret out a criminal who is a menace

to society, it is equally justifiable to use Sherlock Holmes methods in our medical school work in order that the open case may be discovered and educated or isolated and society protected.

As a concrete example of this ferretting procedure, I offer the following case:

William and Lucille F——— were found to be positive reactors by our physician assigned to the Kennard School. Both were examined by him and were sent to a health station maintained by the Board of Health where they were X-rayed. William's X-ray showed healing primary tubercles. Lucille, who was running a temperature afternoons showed the shadow of her right hilum to be denser than normal.

The family follow-up record of the Department of Health nurse indicated that both parents were well nourished healthy people. However, there was a third child, Ruth, age 20 years, who was working as a maid in an East Cleveland home who was reported well by her parents. She was found to be a moderate tuberculosis case with positive sputum and sent to a sanatorium at once for treatment. Ruth was badly exposed to tuberculosis by a maid in this East Cleveland home who occupied the same bed until she was sent to the City Hospital, where she died soon after.

It may be noticed in this case, which illustrates many others, that there was perfect coöperation between the Department of Health Service in the schools and the City Health Department and that there was no duplication of effort.

Add to this combination, the school's Division of Health Education which seeks to instruct the pupil in simple health laws and is interested in his nutrition, and also add the Anti-tuberculosis League with its inspiration and oftentimes funds, we then will have a combination that is quite effective in the handling of the childhood type of tuberculosis problem.

PUBLIC HEALTH NURSING*

Nursing Education in the Future—More and better theory. Less and better practice. These are the two probable changes that the near future will bring in nursing education, according to the Committee on the Grading of Nursing Schools.

There are few forms of education for professional workers in which seven times as much practice as theory is needed. Yet 885 hours of theory is the amount recommended for nursing students by the National League of Nursing Education. The Grading Committee believes this recommended amount of theory should constitute the absolute minimum offered by any school.

Only 22 per cent of the accredited schools studied by the Grading Committee comply with the present "very low requirements" for hours of theory. The typical school gives 124 less theory and 843 hours more practice than the League standards contemplate, the Committee finds.—*Western Hosp. Rev.* XXI, 5:13 (July), 1933.

Canadian Appointment of Nurse as Health Consultant—The Ontario Department of Health, through the recommendation of the Minister of Health, has made Miss Elizabeth Smellie Chief Superintendent of the Victorian Order of Nurses of Canada, Honorary Consultant in Public Health Nursing. This is an official government recognition of the value of nurses as health counsellors.—*A Nurse as Health Consultant. Canad. Nurse*, XXIX, 5: 234 (May), 1933.

This is right in line with the action of the New York State Department of Health, which recently appointed Katharine Tucker, R.N., Director of the National Organization for Public Health Nursing, as consultant in public health nursing.—*Why Not Make Use of the N.O.P.H.N.? A.J.P.H.* XXIII, 2:170 (Feb.), 1933.

A Visiting Nurse Association Serves Research—A principle found in the urine of pregnant women was being studied by the Biological Laboratories of E. R. Squibb & Sons, New Brunswick, N. J., in 1930. It was difficult to get an ample supply of such urine and the New Brunswick Visiting Nurse Association was consulted about ways and means. The director and her staff nurses picked out 6 prenatal patients who, they thought, would be glad to earn some money in this way and a routine was arranged with the Squibb Laboratories for 3 months.

When the trial period was over the Laboratories were sure their product was of value to the medical profession but they needed an increased supply of urine, collected between the 3rd and 8th months of pregnancy. More prenatals were put on the Squibb list, and each patient was turning in three 1-gallon jugs of urine a week to the Visiting Nurse Association Office where it was collected by Squibb. In the 2½ years this plan has been in operation, \$8,000 has been distributed to 199 expectant mothers.

The Medical Advisory Committee of the V.N.A. was consulted from the beginning of the experiment. Each staff nurse "selected cases in her district, explained the purpose of the plan to the

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

patient, taught the patient the collection routine and checked up failures. The office staff supervised the exchange of bottles at the office and took care of the cash payment received from E. R. Squibb & Sons."

The financial need of the family was considered in choosing the patient. The nurses had to be sure the money received for the urine was well spent and had to plan with the patient, the physician and the relief agencies to this end.

Whenever the urine was not acceptable, whether for a pathological or a chemical reason, the visiting nurses were notified and they in turn notified the private physician, the clinic and the patient. The patients tried to follow accurately the nurses' instructions for payment ceased if the urine did not measure up to acceptable standards. In several specimens the chemical constituents were not right, apparently due to the faulty diet of the prospective mother. On this problem the staff nurses of the V.N.A. and the Home Economics Department of New Jersey College for Women in New Brunswick worked together to the benefit of all.

Private physicians, the city physician, the hospital, the emergency relief administration, the charity organization society and the Overseer of the Poor all met together to discuss this plan as it related to families on the relief rolls of the city.

Soon after the plan was under way Squibb requested the V.N.A. Medical Advisory Committee for advice as to how they could be assured that the women from whom collections of urine were made were free from syphilis. This committee and the physicians caring for maternity cases in the community consented to have a smear and a Wassermann taken on each patient in the

Squibb Laboratory. A confidential report of the findings was sent to each patient's physician.

"All in all this unusual plan has been of great service to the patients, the research laboratory, the social agencies, the private doctors, the hospitals and the community in general."—Emma Rae McLeod, R.N. and Margaret B. Wright. *A Community Serves Research, Pub. Health Nurs.*, XXV, 8: 436-438 (Aug.), 1933.

For Superintendents and Supervisors Only—The nursing personnel of a well regulated hospital or public health nursing association, figuratively speaking, forms a pyramid. The nursing staff forms the base, the supervisors are above them, and at the top comes the superintendent of nurses. It is by virtue of superior training or superior experience or both that the supervisor should have authority over the staff nurse; mere authority unsupported by superior training or experience breeds nothing but contempt among the nurses who must submit to it.

Here are some of the qualities a nurse has a right to expect of her supervisors always and everywhere: fair play, professional honesty, an equable disposition and firmness of decision. Added to these qualities should be superior training and superior experience.

It is good policy and not below her dignity, for the supervisor to invite constructive criticism of her work from the nurse's point of view. Staff nurses are much more apt to act like human beings if they know they have a human being over them who dares to admit now and then that she is infallible.—*The Nurse Looks at Her Supervisor*, by Harlan C. Koch, Ph.D. *Trained Nurse & Hosp. Rev.* 90, 7:39-41 (July), 1933.

EDUCATION AND PUBLICITY*

Prenatal Letters Increasing in Demand—The use of the prenatal letter service offered by the Division of Maternity, Infancy & Child Hygiene was greater by more than 50 per cent in 1932 than in the year before, reports the New York State Department of Health, in *Health News* (Albany, N. Y.), May 22, 1933.

Distribution through nurses and clinics accounted for 83 per cent of the names on the mailing list.

The Parents' Book, carrying a coupon for the prenatal letter service, was sent automatically to each bride when her marriage was recorded. Almost every mail brought returned coupons, and those who received the letters frequently sent in the name of a friend.

The increased use of the service was due in large part to the continued support of nurses throughout the state working individually or in organizations such as visiting nursing associations, the American Red Cross, and insurance companies. During the past year, one large insurance company approved the prenatal letters for pregnant women insured by them and another continued to refer many expectant mothers under its care. Boards of health of several cities also made liberal use of the service.

"Better Health Verse at Hand"
—Says *Ohio Health News*, Columbus, May 15, 1933:

Better health verse for children is coming to the front in some of the recent books. Only a few years ago virtually all material of this kind was inane, to use no harsher term; much of it was silly and a large proportion was badly written. Excerpts from three of the latest books, *Little Miss April*, by Anne Robinson; *Skiping Along Alone*, by Winifred Welles, and *The Bucking Burro*, by Nancy Ricket Ranson, have come lately to editorial attention, and all reflect a vast improvement over run-o'-mine stuff of hardly more than yesterday. Any mother who still finds opposi-

tion and resentment when she places the carrots and spinach on her little one's plate is likely to appreciate this bit of verse, taken from "Old Bossy," as found in *The Bucking Burro*:

I asked our cow, Old Bossy,
Who gives delicious milk,
"Why is your skin so glossy,
And soft as finest silk?"

She ate her beets and carrots—
"Why! don't you know?" she said,
"Green vegetables and cereals
And early hours to bed!"

Little Miss April is from the Oglethorpe University Press, Miss Welles's book is a Macmillan publication, and *The Bucking Burro* is from the Kaleidograph Press.

"Healthland" at Farmers' Picnic—Healthland, an exhibit arranged by the County Department of Health, was one of the chief centers of attraction at the Farmers' Picnic in Cattaraugus County, June 24, 1933.

The clanging of the bell on the "Healthland Special" train attracted a throng of children and their parents. The eager children were weighed and measured and given their tickets by the nurse. After these preliminaries were attended to the jovial conductor assisted the children down the steps and into the spacious, brightly painted coaches. The engineer received his signal and with a toot of the whistle and the clang of the bell they were off for the Land of Health.

Upon their arrival at the Gate of Healthland the children had their tickets punched indicating the various stations at which they should stop while in Healthland. A nurse accompanied the children and emphasized the health rules which were suggested by the exhibits, or "stations," as follows:

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evert G. Reutzahn, 120 East 22d St., New York, N. Y.

"Playmeadows," "Drinkwater," "Sunshine Park," "Land of Pearls," "Bath-tubville," "Milk Station," and "Sleep Mountain."

The show was held under the grandstand. A tractor and several trucks were the basis of the "train." Empty oil drums and wall board, with vivid paint completed the picture. The round trip ticket entitled the child to a train ride to the stations or the exhibits, and to a return ride to the starting point.

For a description of the ingenious exhibits and snapshots of the train write to Dr. J. Warren Bell, County Dept. of Health, Olean, N. Y.

A 2,000 Year Old Idea—The father's part in child welfare is receiving much attention among health workers in England and Ireland. *Mother and Child*, London (June, 1933), says:

All those who are advocating the study of fathercraft as a factor in the child welfare movement may not be aware that as a matter of history the idea of fathercraft actually preceded that of mothercraft. Dr. Eric Pritchard, speaking at the third annual conference of Fathers' Councils at the Violet Melchett Infant Welfare Centre on March 23, 1933, pointed out that nearly 2,000 years ago Plato claimed that the bringing up and education of children was so important a matter to the State that this duty should be undertaken by its most intelligent members. These Plato considered to be men and fathers. Dr. Pritchard also pointed out that Dr. William Cadogan, a well known London physician in the year 1760, held the view that fathers ought to take a hand, owing to their superior intelligence, in the care of infants. He regarded this, the modern revival of an old belief, to be extremely valuable to the welfare movement.

"Interpreting Medicine to the Public"—This is the title of a clear and readable account of the work of the Medical Information Bureau of the New York Academy of Medicine, by Dr. Iago Galdston, its director.

In its credo, the objectives of the Medical Information Bureau are defined as follows:

"(1) to facilitate the dissemination of authentic information on medical and public health matters, (2) to stem and curtail quackery, and (3) to promote a better understanding between the public and organized medicine."

If it were not for the bizarreness of the expression, the Information Bureau might well be called the intelligence service of the medical profession, comparing it in a sense with the intelligence service of the army. That this view of the Medical Information Bureau is not entirely fanciful is attested to by the fact that many medical associations throughout the country have shown a marked interest in the bureau and some have established similar organizations. More than that, in the City of New York, the legal profession has followed suit and has also created an Information Bureau.

Quart. Bull., Milbank Memorial Fund, 40 Wall St., New York. July, 1933. Copy free.

Wanted at Indianapolis—Most important to show at "Education and Publicity" headquarters is whatever new and good materials have been produced by our readers and other public health workers.

The headquarters display is made up of (1) portfolios of samples and information on method; (2) some portfolios of assembled subject matter samples; (3) portfolios sent by public health workers; (4) portfolios supplied by a few national health agencies, or concerns doing a certain amount of health work; (5) a few selected devices and materials.

Please write, as suggested elsewhere, about what you have.

Samples of materials which could be included in the first and second groups of portfolios noted above should be sent early to

Indianapolis Display
Ewart G. Routzahn
130 East 22d St., New York

Whether or not you have already sent to the editor samples of printed or mimeographed material, please send copies now to the address above.

Subjects on which material is

especially desired: public health and health organizations in the depression; presenting health topics to groups at any time and anywhere by any method.

Write Before You Pack—Please write before you take or send an exhibit or display, even a chart or portfolio, for the Annual Meeting at Indianapolis, October, 1933. When two or three people turn up without making advance arrangements a lot of trouble results.

All display space at Indianapolis will be limited. Education & Publicity will have a plan for its limited space. *So please write about anything you will have to display.* Write about any class of Exhibits to American Public Health Association, 450-7th Ave., New York.

"Mass Education"—The Milbank Memorial Fund (40 Wall St., New York) *Quart. Bull.*, July, 1933, prints Bertrand Brown's thoughtful analysis of the essential steps in "Mass Education." This paper was read before the Health Education Institute of 1932.

The essential steps are indicated in a four-part question:

- (a) What facts and ideas must be secured,
- (b) to transmit through what media, (c) to what audiences, (d) to accomplish what objectives?

Whether he is discussing a, b, c, or d, Mr. Brown continually drives home the need for simplification:

However small their cost, the most expensive mass educational efforts are those which are unheard, unread and unseen. Too often publication is premature, before the material presented has been authenticated and put into a form which will not only engage the reader's attention and interest but be read and understood by him and gain his confidence and support.

Take, for example, the hypothetical case of Mr. Alan Blank, banker and leading citizen of Buckeye Falls. He is used to getting it "on a silver platter"—to having it meet him more than half way. His research faculties have been dulled by a continuous diet of

books, magazines and newspapers—the contents of which must be "full-baked" to have their media survive. He chooses to receive this "predigested" literature and pays for it. He doesn't have enough time to read as much of it as he would like. When he receives gratuitously a body of information phrased in a writer's technical jargon, it is not surprising, therefore, that it fails to interest him. He fingers it, decides not to exercise the disciplinary concentration which a reading would require, lays it aside, forgets it, and thus nullifies in so far as he and his influence are concerned the return on the investment of money and effort which have gone into it, from the initial research to the final mailing.

A chart of "Media of Communication Available for Use in Mass Education" classifies the media according to the amount of selectivity of the audience that each channel allows.

A group of 8 photographs show vividly the modern communication systems which make it possible for the masses to receive simultaneously as a nation, ideas, images and emotions.—M. S. R.

Current Facts on Health—"Source Material for the Publicity Desk" is the sub-title of a series of bulletins issued in 1932 by the United Educational Program of the National Social Work Council. A supplementary series for 1933 has just been issued. Of the 10 supplements six deal with health topics under the titles: "Health" (including child health and nutrition), "Public Health Nursing," "Social Hygiene," "Tuberculosis," "Mental Hygiene," and "Hospitals." Other topics in the series are: "Family Welfare," "Child Welfare," "Transients," and "Character Building," all of which have health aspects, although they are not brought out in these bulletins.

Each bulletin contains several pages of brief paragraphs and suggestions of further material. The editors of the series say:

In supplying this source material, we visualize its local use in informative talks, articles,

letters and discussions apart from and probably in advance of money raising campaigns.

It is the aim of the editor to include in each bulletin of this second series only such facts, figures and statements as have become available since the earlier bulletin on the same subject was issued. For this purpose, known sources of reliable information have been canvassed as fully as possible. When you are looking about for a fresh slant, you may in glancing through the bulletin on your topic feel reasonably sure that it tells, or refers to, whatever any established national agencies have compiled or discovered this year that is new or different and of public interest.

Is There Any News?—Any evidence of change has news value. The bulletin on Public Health Nursing reports that "Nursing organizations everywhere are able to carry their load only as they shift the emphasis in their programs from teaching people how to keep well to caring for people who are already sick." There is a story in the comparison of this statement with the local situation, together with an interview with the right person on the poor economy of allowing this neglect of the nurses' educational program to continue.

Is There Any Fresh Material?—Another evidence of change mentioned in the same bulletin is contained in the report of a study in New York State which revealed that illnesses lasted much longer among a group of families who were victims of the depression than in similar families studied in pre-depression years. Check up this statement with local health authorities. Is the local situation in regard to length of illness similar?

While the facts contained in the bulletin are not spot news, their publication in this form makes an occasion for restating them in news stories in combination with local information. A letter to the editor may be a more appropriate form for brief treatment of some of the material than a news story.

Do You Find Any Ideas for Feature Articles?—In some of the bulletins the material as a whole can be rearranged and restated to make a feature article illustrated by local facts, figures and examples. More often a better use of the bulletin would be to draw from its headlines, its examples, or its statistics, ideas to propose to local special writers, together with a promise of more source material from your own files.

Could Your Editors Use the Bulletins?—If your relations with the local editors are such that you can from time to time call material to their attention, you may wish to mark up certain issues of the bulletin to send to them. In fact there is probably a greater wealth of material in the bulletins for editorial writers

than for either news or feature articles—material that lends itself to comment and to treatment in brief form.

Are You Looking for Fillers?—As you go through the bulletins you may note sentences or paragraphs to mark for possible use in your house organ or campaign handbook. What Dr. Welch said about America's two unique contributions to medicine is a paragraph of this kind.

Single copies, 10 cents. The set of 10, or any 10 copies, 75 cents. Community Chests & Councils, Inc., 1810 Graybar Bldg., New York.

If you have an idea on which you think more material might be had from a national source, or if you can contribute helpful data, write to Mabel B. Ellis, Editor, Behind the Front Lines, 130 East 22nd St., New York.

Attractive Information About Low Cost Diet—Some of the obvious publications on depression diets are less useful than others. Some are so deadly dull in appearance. Others are complicated for ready reference. Some are far better for the health or social worker than for the harassed housewife.

Whether one wishes to recommend material published by others, or wishes to re-publish or to re-write for local publication it would be well to compare some of the already published material.

The best of the inexpensive material available nationally is listed in *Some Publications on Low Cost Diet*. Social Work Publicity Council, 130 E. 22d St., New York. 6 cents. Classified with brief descriptions of publications to be secured at low rates for workers or for clients, or to be republished locally. Publications issued in the United States or Canada.

A collection of this material could be displayed at the public library, the health department or the health association.

In addition to any free distribution it is likely that some of the "white collar" housewives might be interested

in certain of the publications sold at 5 cents or 10 cents a copy. The health department or association might arrange for such sale through a coöperative book seller even though he sold them at cost.

Hygeia for August, 1933—"The Facts About Proprietary Foods" (the problems; what the American Medical Society has done; a proposed book on "Accepted Foods"—and the unaccepted); "Forty—Looking Forward" ("the beginning of a man's usefulness"); "Dog Laws" ("for those who love dogs but love their children more"); "In the Shadow of the Needle" (a diabetic patient); "The Cross-Eyed Child" ("early treatment will correct this handicap"); "Vitamin D Milk" (what it is, how prepared, proper way to use it); "Thinking of Studying Medicine" (what to expect); "Egg Free" (substitutes for eggs); "The Effect of Teeth on Facial Expression"; "Exhibits of the A.M.A." (pictures of modeled figures of medical leaders); "Preventive Psychiatry" ("facing the facts of reality squarely and frankly"); "Training for Athletics & Health" (correcting physical defects); "Safeguarding the Take-Off for School"; "Sex Education" (plant and animal reproduction); "Eating Under the Sky" (how the day may be "perfect"); "Progress in Preventive Medicine" (respiratory diseases); "School and Health" (includes "Teaching Health" and "New Health Books and Teachers' Materials.")—American Medical Association, 535 N. Dearborn St., Chicago. 25 cents. Sample copy free.

Suppose We Compare Notes—The unlovely effect of poison ivy on the editor of this department makes poison ivy information of special interest.

Material has been gathered from a group of state health and agriculture

departments and other sources. "The facts about poison ivy," its prevention and first aid medicines vary quite a little. For example: "Some persons are so susceptible that they are affected even by passing near the plant" *versus* "Despite the mass of hearsay evidence, ivy poisoning is not borne by the air."

Do we thus disagree only about poison ivy, on which agreement should be more easily possible than on some other subject?

A Radio Contest—Prizes of \$20.00, \$10.00, and \$5.00 are offered for the

best radio sketch presenting the whole subject of public health nursing or any phase of it. The sketch may be in the form of a dialogue, a dramatic sketch, a playlet, a story, or a recitation of any kind; it may concern one patient or many, the preventive or curative side of the work, the state, county, or local program—but it must tell something of importance about public health nursing in a way that will make people listen, and be appropriate for the radio. It must not consume more than 12 minutes to present and therefore should not be longer than 1,500 words, shorter if possible. The contest is open to anyone. Individuals may send in as many entries as they wish. The three judges will represent the public health nursing field, the non-professional radio audience, and the radio broadcasting experts.

The contest closes midnight, October 15, 1933, and the winning sketch will be published in the December number of *Public Health Nursing*. It is hoped that it will also be possible to arrange for broadcasting the winning sketch—either locally or nationally as seems appropriate.

Manuscripts signed by a pen name should be sent to Contest Editor, *Public Health Nursing*, 450 Seventh Avenue, New York. They should be accompanied by a sealed envelope containing pen name and real name and address of the author.

REPORTING

"Statistical Summary for 1932," the April-June, 1933, issue of the *Bulletin* of the Detroit Department of Health is mimeographed "in the interest of economy." Twenty-three letter size pages, with cover.

"Twenty-five Years of Saving Sight" is the title of a report issued by the National Society for Prevention of Blindness, 450-7th Ave., New York. Striking gains during a quarter century are presented in attractive and quickly grasped picture diagrams, one of them on the cover. The brief illustrated review of 25 years occupies 3 pages preceding an 8 page annual report.

Hygeia for July, 1933—Some of the articles in *Hygeia*, 535 N. Dearborn St., Chicago, July, 1933:

"Sex Education (Ideals and Purposes)," "A Century of Progress" (A.M.A. exhibits), "Live Statistics," "Babes in the Woods" (vacation health problems), "Are Foods Truthfully Labeled?" "Safe Swims for Campers," "Training for Athletics and Health," "The Dangers of Spider Bites," "Eradication of Tuberculosis from Cattle," "Eye Hygiene—Eye Education," "Progress in Preventive Medicine," "Shoes Have Tongues," "Speaking of Hair," "School and Health" (a department).

DEPRESSION DISCUSSION

"An Illuminating Contrast" is a diagram and a page article emphasizing the per capita outlays in Kentucky for medicines *versus* public health. *Bulletin*, State Board of Health, Louisville, Ky. July, 1933.

"Essential Health Activities," a release from Iowa State Department of Health, quotes the AMERICAN PUBLIC HEALTH ASSOCIATION on the essential five types of activities, and then illustrates their significance in relation to the whole:

The State Department of Health provides that due emphasis be given to each of the above mentioned activities. To illustrate how these five essential functions are inter-related, the interest of the various bureaus in the newborn baby, pre-school and school child may be cited as an example. Child health is safeguarded by providing information and instruc-

tion for the mother which will enable her to give the child such care and training as will make possible his highest mental and physical development. Through the Bureau of Vital Statistics, complete and accurate birth registration is kept, as well as records indicating deaths which occur among children from such preventable diseases as diphtheria and tuberculosis. Contagion is prevented or controlled against further spread through the encouragement of immunization early in life, through the prompt reporting of infectious disease and through coöperation between the State Department of Health and health officers in local communities. Public health laboratories and sanitary engineers provide additional bulwarks of protection about child life, through the procuring and analysis of samples from public water and milk supplies and through various tests of specimens forwarded from those suspected of harboring disease germs. Through improvement of sanitation animal and insect-borne diseases are held in check.

SCHOOL—THE CHILD

"The Hunger Strikers," by Gertrude Thomas. *American Journal of Nursing*, 450-7th Ave., New York. Feb., 1933. Why some children don't eat certain foods and what might be done. 35 cents.

"Alcohol," by J. F. Rogers, M.D. *School Life*, Washington, D. C., May, 1933. 5 cents. "How changing liquor laws revive a teaching problem."

"Health-Service Activities," by W. A. Kincaid. *School Executives Magazine*, Lincoln, Neb. June, 1933. 35 cents. Includes case stories of "Typical Cases of Neglect."

"When the Baby Cries," by W. A. O'Brien. Minn. State Medical Assn. *Everybody's Health*, 11 W. Summit Ave., St. Paul, Minn. July, 1933. 10 cents. Radio talk.

MOTION PICTURES

The following new pictures are bulletined by the Department of Commerce, Washington, D. C.

"The House Fly": motion photomicrographs of structures of the house fly which help to make it a health menace. Dangerous habits, rapidly

of breeding and methods of controlling this filthy insect are shown. 15 minutes. Silent. 16 mm. Sold. Eastman Teaching Films, 343 State St., Rochester, N. Y.

"Good Hospital Care" dramatization of service in an approved hospital from the time the patient enters until she leaves. 22 minutes. Sound. 35 mm. *Free*. Distributed by American College of Surgeons, Chicago, and Petrolagar Laboratories.

"The Conquest of Diphtheria": story of diphtheria from the "onion poultice day" to the present positive methods. 15 minutes. Silent, 16 mm. and 35 mm. Metropolitan Life Insurance Co., 1 Madison Avenue, New York.

EDUCATIONAL MATERIAL

"Health Through the Ages," by C.-E. A. Winslow and Grace T. Hallock. Metropolitan Life Insurance Co., New York and Ottawa. *Free*. Selections from the table of contents will indicate the nature of this 64 page pamphlet; "Health in the Stone Age," "The Hebrew Health Code," "The Black Death," "The Lady with the Lamp," "The Secret of Contagion," "The Conquest of Yellow Fever." It has many audiences, and is a splendid contribution to spreading an appreciation of the scientific background of medicine and of public health.

The 1933 edition of "Books on Tuberculosis" lists all of the best English and American texts by subject, with an alphabetic author list. *Copy free*, *Journal of the Outdoor Life*, 450-7th Ave., New York, N. Y.

"Publications — Periodicals — Motion Pictures on Tuberculosis." 16 pages. *Free*. 1933 edition of catalogue of materials issued by National Tuberculosis Association, 450-7th Ave., New York, and available through state tuberculosis associations.

"Public Health Education: The

Functions of the University and of the Private Foundation," by John Sundwall, M.D. Reprint from *Public Health Reports*. Supt. of Documents, Washington, D. C. 5 cents.

"The Tuberculosis Problem in Missouri," by Dr. Scott P. Child. Reprint from *Journal of Missouri State Medical Assn.* Missouri Tuberculosis Assn., 2221 Locust St., St. Louis, Mo. 7 pages. 3 cents. Includes need of education (of medical profession; medical student, general public).

Single copies of the following (enclose 3 cents postage) will be supplied by Dr. J. W. Wisan, Council on Mouth Hygiene, N. J. State Dental Society, 1143 E. Jersey St., Elizabeth, N. J.:

"Give Him Good Health," an especially good 6-page *illustrated* folder "approved for distribution in public schools" in New Jersey.

"Who Should Present Dental Health Information to the Pupils?" by A. G. Ireland, M.D. Reprint from *Dental Cosmos*. May, 1933. Calls for team work.

"Mouth Health of School Children," by Pauline B. Williamson. Winning the coöperation of the children.

The National Society for the Prevention of Blindness, 450-7th Ave., New York, N. Y., offers the following reprints and original publications:

"Diet and Eye Health," by Walter F. King, Buffalo. 8 pages. 5 cents.

"Vision and Other Tests for Automobile Drivers," by Maxwell Halsey. 14 pages. 15 cents. Valuable study of drivers' examinations.

"What To Do for Cross-Eyes," by Dr. Walter Baer Weidler, New York. 2 pages. 5 cents. For nurses, social workers, parent-teacher associations.

IT MAY BE HERE

Circular letters are being mailed at irregular intervals to local milk producers and dealers by the Attleboro, Mass., Health Department. They are

friendly, straightforward explanations of new regulations and reminders of old ones. Copies supplied upon request.

"A Cough in the Night" is the title of a news release on whooping cough issued by Iowa State Department of Health.

A directory of "Whole-Time County Health Officers, 1933" appears in *Public Health Reports*, Washington, D. C., July 14, 1933. 5 cents.

"Informing the Public and Money Raising," by Alma C. Haupt. *Public Health Nursing*, 450-7th Ave., New York. 35 cents. "A resumé of recent methods in 65 public health nursing associations," with illustrations of a circular card telephone number record, and of a beaver board poster with bristol board cut-outs. Aug., 1933.

The June 28, 1933, "Letter to Periodical Publishers," National Better Business Bureau, Chrysler Bldg., New York, gives reports from Federal Trade Commission on Trigestia Tablets, obesity remedies, etc. Copies free to health agencies.

"A Memento of Public Health Work in the Eighties" reproduces what is probably the first official badge worn by a member of the State Health Department of New York. In *Health News*. July 17, 1933. A reminder of the news value of old publications, records and miscellaneous matters.

"The Public Health Nurse," by Dr. J. D. Dowling, Health Officer, Birmingham, Ala. In *Public Health Nursing*. Aug., 1933. Radio talk.

Public Safety, National Safety Council, 20 N. Wacker Drive, Chicago, for Feb., 1933, is interesting for its cover made up of newspaper clippings on a blue background; several picture diagrams; and its review of "Oddest Accidents of 1932" (quite readable, with quotable warning examples). 10 cents.

The 17th National Baby Week was held in England, July 1-7, 1933.

"She's Had the Doctor!" by W. E. Chase. *Atlantic Monthly*, Boston. June, 1933. 40 cents. Drama of the doctor's visit; low cost of medical care in early New England days; home remedies and superstitions.

"Speech Material," by Lena D. Dietz. *Trained Nurse*, 468-4th Ave., New York. July, 1933. 35 cents. Talk suggestions; brief outlines for a variety of talks.

"A Study of Mortality by Specific Causes of Death in Thirteen Large American Cities," by W. S. Groom. Public Health Federation, Cincinnati. "Introduction" and "Section 1—Scarlet Fever." 10 pages. First of a series. 10 cents. Comparative usable data.

Time is passing for the enrollment of your city in the Inter-Chamber Health Conservation Contest. Address the AMERICAN PUBLIC HEALTH ASSOCIATION.

HONORABLE MENTION

To National Health Library of National Health Council, 450-7th Ave., New York: for including the publication city with all periodical references in weekly issues of *Library Index*.

A Diphtheria Display Idea—V. T. Schuhardt, A.M., and S. M. Bohls, M.D., of the State Hygienic Laboratories, Austin, Tex., have developed a placard display against diphtheria. It is an adaptation of the Hamilton, Ontario, display illustrated in the *Journal*, August, 1932.

Statistics as to cases and deaths before and after introduction of immunization, is emphasized at the base by rows of crosses representing deaths in selected years.

Supplementary to the Hamilton comparison are two outline maps of Texas, one crowded with crosses for 1931, the other questioning the number to be expected in 1941.

Address the authors for the loan of a photograph.

BOOKS AND REPORTS

Medical Biology. A Laboratory Manual of Bacteriology, Mycology, Immunology and Parasitology; Consisting of Experimental Guide, Interpretive Text, Atlas and Protocol Form—By William Barnard Sharp, M.D. Galveston: Medical College Edition, 1933. 443 pp. Price, \$4.50.

This book has apparently been the product of courses as given by the author under rather peculiar local circumstances in the school from which the publication comes. It is doubted that it would find adaptation in similar departments of other schools.

There are some commendable features, especially in the diagnostic and clinical discussions, which are of practical value. There are some mistakes in spelling, as "hemaphroditic." In the paragraph, "Fertilization with Night-soil" occurs the ambiguous statement, "That with animal manure does no harm, because germs of intestinal infection in man do not affect the domestic animal"

In some respects, the material is quite elementary for students in a school of medicine. It is not strictly a text for use in bacteriology, for it contains considerable non-bacterial matter. As a laboratory book or guide, or as a notebook for recording observations and conclusions, it is too voluminous in didactic material. In many instances where details should be given, they are deficient or absent. Under the description of blood cultures, no detail of the procedure is given for culturing quantities of blood in fluid medium, which is the only one of practical value. The plate method of blood culture, which is given in detail, is often not satisfactory in clinical medicine. The same may be

said of the plate culture of urine in typhoid fever.

Droplet infections, diphtheria of wounds, and a number of similar common conditions are not mentioned. Under "Milk Borne Disease," undulant fever receives no mention.

The statements in the chapter, "The Tubercle Bacillus" that the bovine variety infects infants and young children about as often as the human, and that aside from the occasional alimentary or meningeal infection, the bovine type is relatively mild and usually of lymph glands only, are not in conformity with the impression held by most authorities.

The author has made a commendable effort in illustrations of his personal production, but unfortunately many of these fail to illustrate. The absence of a scale for illustrations is always a fault. Numbers of the illustrations are ill-chosen, too small, reveal a lack of contrast, and fail to reveal the object to be shown. The wide use of photomicrographs to show morphology of bacteria, such as the types of staphylococci or the Gram negative bacilli, is unfortunate when there are in reality no morphologic differences in these groups possible of being shown in the illustration. M. PINSON NEAL

Reports, National Quarantine Service, Series III—1932—*Edited by Wu Lien-Teh and Wu Chang-Yao.*

The Chinese National Quarantine Service has issued recently the third in a series of annual reports inaugurated in 1930, which shows in a very interesting manner the work accomplished and the progress made by this comparatively new organization during the past year in spite of almost insurmountable ob-

stacles resulting from military operations involving a considerable part of the country. Consistent improvement is manifested each consecutive year in the three annual reports issued to date. The English text of the third report is most excellently written and contains very interesting data, intelligently and entertainingly presented.

The preliminary results of rat and rat-flea surveys of several principal ports are published in this volume. For the first time in the history of the country, a systematic rat-flea survey of the principal ports of China was undertaken, with the intention of continuing the work until accurate data have been assembled concerning the species of rats and rat fleas found in the various ports.

Research into many other problems of port health is being conducted, and the report shows that routine work of inspection and fumigation is being placed on a more methodical basis in the nine ports in which the Service is now operating. The port health services of Tientsin, Taku-Tangku, and Chinwangtao were formally taken over by the National Quarantine Service on April 6, 1932, making a total of nine ports now under the control of the Service.

The report presents a brief history of the Manchurian Plague Prevention Service, which has enjoyed an international reputation in scientific circles through the work of its modern research institute and unique plague museum, but which now practically exists in name only as a result of the military occupation of the North-Eastern Provinces which culminated in the seizure of all the public services hitherto functioning there under the Central Government. The headquarters of that Service, however, have been transferred from Harbin to Shanghai, where an effort is being made to continue the work under the new conditions.

The results of a survey made of plague in wild rodents and of a new survey of pneumonic plague, which would ordinarily have been published in the reports of the Manchurian Plague Prevention Service, are presented through the medium of the *Annual Report of the Chinese National Quarantine Service*. The new evidence collected in these surveys tends to show more clearly than ever the great extent to which wild rodents are involved in the perpetuation and spread of plague. The report expresses the hope that the new anti-plague serum which has given such promising results in the treatment of bubonic plague in India will also prove to be useful at least in the prevention, if not the treatment, of the pneumonic type.

During the past year, the resources of the Chinese National Quarantine Service were taxed to the utmost by the devastating cholera epidemic which invaded 23 provinces and 312 large cities of China, with a death toll of nearly 34,000, and by the outbreak of smallpox which occurred in Amoy. Detailed accounts of both epidemics are given. Encouragement is found in the fact that the intensive anti-cholera measures which were taken in Shanghai resulted in that city having the lowest mortality rate of any of the large cities involved, though it had the largest number of cases.

Interesting chapters are included on "Some Aspects of Modern Quarantine," "Port Health Work in Singapore," and "Refugee Relief and War Casualty Work in Shanghai." The volume is brought to a conclusion by the incorporation of detailed reports of the Boarding, Fumigation, and Medical Services Divisions, and of several of the port quarantine stations at present under the supervision of the national quarantine service. Instructive data are furnished in the form of tables, charts, and maps, and a large

number of illustrations add to the interest in the publication. A note of optimism runs through the entire report, and the reader is left with the impression that no opportunity will be lost by the Service to attain high efficiency.

F. A. CARMELIA

The Approach to the Parent: A Study in Social Treatment—*By Esther Heath. New York: Oxford University Press, 1933. 163 pp. Price, \$1.25.*

In dealing with personality deviations and behavior disorders in children, the one outstanding finding is a faulty relationship between one or both parents and the child. The therapy therefore consists, to a large degree, in treating the parents. This is well exemplified in the handling of the four boys whose problems are set forth in this book. It clearly shows that successful results are obtainable if a worker is capable of evaluating the material and proceeding accordingly.

By contrasting the social technic of 8 years ago with that employed at the present time one readily sees the strides that have been made in social case work.

The author stresses the all important therapeutic fact of the relationship between worker and client, and one closes the book more firmly convinced that the situation between the person who gives help and the one who seeks it is a recapitulation of life's patterns, and the outcome of this relationship is, to a large extent, a determiner of future relationships of the patient, whether he be an adult or child.

The cases presented are somewhat typical of the intake of a Child Guidance Clinic and if carefully read the contents of the book show the methods and time necessary for good results.

The advantage of including the Summary of Clinic Findings and Recommendations in the appendix is questionable because the reader's task

is less easy. However, such an arrangement prevents the presentation from resembling the usual topical case history as the material is presented chronologically. This arrangement also affords the author the opportunity of giving the facts in a less stereotyped manner and wording.

To those who are interested in social therapy of problem children, to the sceptics who doubt that a social worker can do anything, and to the uninformed who wonder how applied psychiatric social work can transform a "bad boy into a good one," the book will be of value.

ELIZABETH I. ADAMSON

Nervous and Mental Diseases for Nurses (2d ed.)—*By Irving J. Sands. Philadelphia: Saunders, 1933. 281 pp. Price, \$1.75.*

This book starts out in the old stilted way to give a long description of Elementary Neuro-Anatomy, on which it is very difficult to concentrate. Speed the day when people who write textbooks will start with the specific and then go on to the general!

The best and clearest chapters are "The Glands of Internal Secretion" and "Psychoanalysis for Nurses." The author commendably puts a great deal of emphasis on the prevention of nervous and mental diseases, and his chapter on Mental Hygiene shows he is thoroughly up-to-date on this.

A more readable and a more effective book on this subject would give the nurses more of the philosophy of dealing with patients suffering from nervous and mental diseases. They need a little inspiration.

Many pages are hard to read because the text lacks sufficient subheads and italics. Moreover, in these days when many nursing schools are giving their freshmen courses in English it seems a shame that any textbook they read has not paid careful attention to correct English.

EVA F. MACDOUGALL

Stop That Smoke!—By *Henry Obermeyer*. New York: *Harper & Brothers*, 1933. 289 pp. Price, \$2.50.

Mr. Obermeyer has accumulated an amazingly large amount of information and has set it forth in interesting and carefully arranged order. He is trained in journalism and is assistant to the Vice-President of the Consolidated Gas Company of New York.

The connection between smoke and disease as given is, in part, as follows:

Any agency that is capable of crumbling a skyscraper and withering a tree may be said to admit of some harm, at least, to the human anatomy. Almost every type of respiratory disease is aided and abetted by the presence of smoke. When the delicate membranes of the eyes, nose, throat and lungs are cut by sharp particles of unburned cinder and irritated by noxious gases, while the breathing-space of the lungs is clogged and blackened with soot, it may be imagined that these organs readily become favorable soil for bacterial and other infections. . . . Today there is almost a direct ratio between the incidence of smoke and pneumonia. A similar relation is seen in the prevalence of rickets. . . .

There are chapters on the harm done to property and health by smoke; the legal, administrative and economic aspects of smoke abatement; and the practical measures which should be taken to secure the proper consumption of fuel.

One of the most helpful parts of the book is the one which deals with the means of carrying on the war against smoke, as illustrated by the experience of many cities, including Chicago, Cincinnati, Pittsburgh, Rochester, Buffalo, Boston, Nashville, Atlanta, and Indianapolis.

The "most promising development of recent date" is considered to be the organization of a Pure Air Committee under the auspices of the American Association of Mechanical Engineers to direct and coördinate present and

future problems relating to air contamination, develop model smoke laws, and serve as a clearing house for research.

There are 8 pages devoted to a bibliography of smoke fighting, and an unusually full index.

GEORGE A. SOPER

Broadcasting Health—By *J. Mace Andress, Ph.D., and I. H. Goldberger, M.D.* Boston: *Ginn*, 1933. 401 pp. Price, \$.80.

In few fields are recent changes more evident than in school texts for teaching hygiene. The old books on physiology with their anatomical data and lurid descriptions of the interior of a drunkard's stomach have given way to attractive texts, more accurate and far more likely to appeal to the pupil.

The book under review takes advantage of the modern child's familiarity with and interest in radio to throw a glamor about facts of everyday hygiene. Furthermore it is possible for the teacher to turn the printed story into actual reality in the schoolroom by encouraging the pupils themselves to put on a similar broadcast.

The scope of the book is "the whole subject of foods in relation to health and civilization." It is planned for older children below high school age. Controversial subjects like alcohol and tobacco are handled discreetly enough to pass muster with the W.C.T.U. on the one hand and the medical society on the other. The authors do not hesitate to recommend pasteurized milk—though, perhaps, more explanation might have been given as to the reason for pasteurization.

As for the English—well, let us hope that sometime the school child will be as careful of his speech as were the children of the Work Together Room of the Abraham Lincoln School. At least the text sets a good example.

MERRILL CHAMPION

Obstetrics for Nurses—By Joseph B. DeLee. (10th ed.) Philadelphia: Saunders, 1933. 666 pp. Price, \$2.75.

The first edition of this book came out in 1904. All these years this text has been widely used in nursing schools all over the country. The other editions taught predominantly obstetrics as practised in the hospital; this 10th edition puts the paramount emphasis on obstetrics in the home, for, as the author says in the preface, "2,100,000 babies are born in the United States every year, and 1,500,000 are born in their own homes."

Extra emphasis is put on diet in

pregnancy, on the mental hygiene of the gravida and on the ways of preventing puerperal infection, the toxemias and complicated labor. The author sees clearly the public health aspect of the whole field of obstetrics, and, what is more, knows and understands nurses and gets their point of view. He knows they need encouragement and a little philosophy sometimes.

Public health nurses will like the book because of the appreciation it displays of the visiting nurse's rôle in the progress toward better obstetrics.

The book can be recommended unequivocally to all nurses.

EVA F. MACDOUGALL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Health Hazards of Sandblast Dust—Protective outfits for sandblasters were found to vary greatly. Helmets with a positive air supply of six feet of air per minute protect the worker adequately. Properly designed equipment can prevent dangerous dustiness.

BLOOMFIELD, J. J., and GREENBURG, L. J. *Indust. Hyg.* 15, 4:184 (July), 1933.

Recurrence of Milk-Borne Tragedies—The usual varieties of milk-borne communicable disease epidemics are spread before us. Cheese furnished a particularly virulent typhoid fever epidemic, so that, though the number of cases of communicable disease produced in 1932 was less than the previous year, the number of deaths was greater. This annual statement is a valuable reminder.

CRUMBINE, S. J. Epidemics from Infected Milk, Ice Cream and Cheese in 1932. *Child H. Bull.* 9, 4:124 (July), 1933.

How Shall We Measure Antirachitics?—Irradiated milk seems to be the most desirable antirachitic agent

for large scale prevention, conclude these authors who compared it with milk from yeast-fed cows, cod liver oil, and viosterol. They found such discrepancies between clinical units (as measured in results) and rat units that the latter may well be considered misleading.

HESS, A. F., and LEWIS, J. M. An Appraisal of Antirachitics in Terms of Rat and Clinical Units. *J.A.M.A.* 101, 3:181 (July 15), 1933.

Stiffness and Heat Sources—Another study of the effect of dull heat upon mucous membranes. Adequate ventilation or radiant heaters will prevent the "stiffness" caused by excessive heating with dark sources of heat.

HILL, L. Infra-Red Rays, Comfort and Health. *Brit. M. J.* 3781:1096 (June 24), 1933.

Favorable Experience With Whooping Cough Vaccine—Pertussis vaccine administered before an epidemic reduced the mortality from

whooping cough to one-sixteenth of the rate among the control group in this experience in the Faroe Islands.

MADSEN, T. Vaccination Against Whooping Cough. *J.A.M.A.* 101, 3:187 (July 15), 1933.

Yardsticks for Health Projects—Dare we measure the effects of our pet programs in public health, if they can be measured? This writer has the temerity to conclude: "The national bill for public health education is a sizeable one. Of course, we think it ought to be larger. Would it not be economical in this time of depression to find out whether we are actually accomplishing by our efforts what we think we are accomplishing?"

PALMER, G. T. Measurement in Public Health. *Child H. Bull.* 9, 4:117 (July), 1933.

Why B. Tuberculosis Remains in the British Milk Supply—Difficulties encountered in ridding Great Britain's milk supply of tuberculosis are enlarged upon in the contrast of ideas of a health officer and a veterinarian. Both cast envious eyes toward the results achieved

on this side of the water, where they claim the problem is so much simpler.

SAVAGE, W. G., Vs. GOLLEDGE, S. V. The Prevention of Human Tuberculosis of Bovine Origin. *J. Roy. San. Inst.* 54, 1:11 (July), 1933.

British Influenza Research—Throat washings from influenza patients instilled in the noses of ferrets produced a disease transmissible serially. Throat washings from convalescents or patients with ordinary colds produced nothing. Human convalescent sera neutralized the virus.

SMITH, W., *et al.* A Virus Obtained From Influenza Patients. *Lancet* 225, 5732:66 (July 8), 1933.

Immunizing Against Diphtheria With One Shot—One intramuscular injection of a concentrated diphtheria toxoid in woolfat immunized 99 per cent of 103 patients within two months. The practical advantages of this method are obvious, if it proves its value in wider experience.

STRAUS, H. W. Active Immunization Against Diphtheria. *J.A.M.A.* 101, 3:19 (July 15), 1933.

NEWS FROM THE FIELD

ASSOCIATION WOMEN IN PUBLIC HEALTH

ADA E. SCHWEITZER, M.D., *President*

International Congress of Women, Chicago, July 16-22, 1933—The Association of Women in Public Health, a member of the National Council of Women, was represented at the International Congress of Women by the President, Dr. Ada E. Schweitzer, and by Dr. Mary R. Lakeman, Chairman of the exhibit committee.

The Healthknowmeter exhibit displayed there was designed by Dr. Lakeman to make easily available to the public, details of information on public health subjects. On the wall over the exhibit table hung a large poster with numbered questions concerning health, such questions as are frequently asked of public health officials. A file box on the table contained cards answering the questions. The index cards bore numbers corresponding to the numbers

on the poster. The following outline indicates the subjects included in the Healthknowmeter box: (1) Child Health, (2) Adult Health, (3) Health Education, (4) Parent Education, (5) Community Organization, (6) Hospital Service, (7) Laboratory Service, (8) Preventive Medicine, (9) Nutrition, (10) Social Service, (11) Public Health Nursing, (12) Mental Hygiene, (13) Opium, (14) Cancer, (15) Courses of Study.

Many persons visiting the exhibit were impressed with its possibilities of usefulness as an aid to students and to others wishing information. Outlines are being sent on request to all who left names and addresses. The Healthknowmeter will be displayed at the Indianapolis meeting of the American Public Health Association in October.

ADENOIDS AMONG SCHOOL CHILDREN OF NAPLES

AS a part of a general campaign against adenoids in Italy, according to a recent report, 77,000 elementary school children were examined in Naples, and 12,000—about 15 per cent—were found to have enlarged or diseased adenoids. Of the children with this defect almost one-half had to repeat the work of their school grades, and the quality of the work done by the children with the more severe cases was particularly bad. As a result of treatment, which was provided in most cases free of charge at public clinics, the number of "repeaters" has been reduced by almost half, with a considerable saving in the school budget; a great improvement has also been

found in the children's physical development, their general well-being, and their resistance to disease.—*Difesa Sociale*, Rome, Feb., 1933.

SPANISH CHILD HEALTH CENTERS

AS a means of combating the high rate of infant mortality the Government of Spain issued an order on March 30, 1933, for the establishment of a child health center in the capital of each province. These centers are to serve not only the cities in which they will be situated, but also the surrounding territory. Expectant mothers will be given advice with regard to prenatal care, and those without means will be provided with attendants at childbirth, in an effort to prevent puerperal infection. The infant health

Radium Poisoning A Review of Present Knowledge*

ROBLEY D. EVANS, Ph.D.

*National Research Fellow, Physics Department, University of California,
Berkeley, Calif.*

IN some circles victims of radium poisoning are regarded as curiosities, and the view advanced that careful studies of the cases—particularly such fundamental studies as the distribution of radium in the system—are of secondary importance. This view arises from the fact that most of the reported cases arose from uninformed carelessness in one occupation, luminous watch and instrument dial painting, in which protective measures have now been taken.^{1, 2}

The view is untenable, however, for three reasons (1) Careful study of the distribution of radium in victims can contribute to knowledge of bone architecture and to the investigation of analogous heavy-element poisoning cases, such as lead and arsenic. Study of the anemias involved has already led to major contributions by Martland. (2) New cases will continue to appear because some physicians are still experimenting with radium solutions for therapeutic uses; because radium solutions are still peddled by the nostrum

vendors, who realize splendid profits therefrom; and because radium "activators" for the treatment of drinking water—some of which are dangerous—are still sold in large numbers to a gullible public. (3) Thus far every case of radium poisoning has been fatal, but there is no *a priori* reason for believing that a satisfactory cure will never be found.

Cases of true radium poisoning arise where the victim has taken radium into the body, by mouth or by injection, in which case a fraction of the radium taken remains permanently in the body, and the radiation which it continually emits produces the effects described as radium poisoning. It must be emphasized that the modern use of radium in the treatment of cancer usually involves an entirely different mode of use of radium, and cannot result in true radium poisoning. Since only the penetrating gamma radiation of a radium product is utilized, the radium never enters the patient's system, and the exposure is of definite, limited duration. Over-doses of gamma rays will produce pernicious anemia and myeloid leukemia as late as 4 years after a massive exposure,³ but these

* Read at the Fourth Annual Meeting of the Western Branch, American Public Health Association, in Pasadena, Calif., May 30, 1933.

effects are to be regarded as radiation burns rather than as true radium poisoning.

Each of the 40 known radioactive elements has a definite rate of spontaneous disintegration which cannot be altered by invoking extremes of temperature or pressure, or by chemical combination. When an atom of radium explodes it emits an alpha ray, a high-energy, doubly-charged helium nucleus, which will traverse a few hundredths of a millimeter of living matter, and is only brought to rest by expending its energy in ionizing about 100,000 atoms. Gamma rays, similar in nature to X-rays, are also emitted.

The exploding radium atom loses mass, electrical charge, and energy in the emitted alpha and gamma rays. The residue is an atom of radon, a heavy, inert, radioactive gas, which can be observed in the air expired by a victim of radium poisoning.

Half of any given quantity of radon decomposes in 3.8 days, the so-called "half-period." Radon is the principal active agent in the water from radioactive springs and drinking water activators, but its short half-period shows that bottled water will become practically free from radon in about 3 weeks.

Radium, because of its relatively long half-period of 1,600 years, cannot disintegrate rapidly enough to be appreciably reduced in amount during the lifetime of a person. Hence radium, once fixed in the bones of a victim of radium poisoning, holds its deadly alpha ray bombardment of the bone structure and of the blood producing centers at a nearly constant rate.

Radium decomposes into radon. Radon, in turn, decomposes into an element called radium A, and this in turn into radium B, radium C, radium C', radium D, radium E, and radium F (polonium), which disintegrates into lead, the stable end-product of this

decay series. In the gamma ray treatment of cancer, the gamma ray of radium C is principally employed.

Radium is chemically quite similar to barium, hence also to calcium. Efforts to remove radium from the body of a victim of radium poisoning must therefore involve mobilization of the calcium, and must borrow heavily from the body of knowledge which is calcium therapy.

In cases of radium poisoning, at least one other radioactive element is of major importance, because it has been widely used in luminous paint and in radioactive nostrums. It is called mesothorium-1, is a beta ray emitter with a half period of 6.7 years, and, like radium, gives birth to a long chain of radioactive substances, one of them gaseous (thoron), five of them alpha ray emitters, four more beta ray emitters, and has lead as its stable end-product.

As in the case of the radium series, the presence of these radioactive decay products multiplies, in proportion to the number of alpha ray products, the destructive effects which could be produced by radium or mesothorium-1 alone.

The term radium is used in this paper as a convenient abbreviation of the long list of radioactive elements which accompany it, and the effects of mesothorium-1 or of radiothorium are the same.

MODES OF ENTRANCE OF RADIUM INTO THE BODY

It is now possible to distinguish between radium water and "activated" water. The former contains actual radium salts (usually the chloride) which, because of the long half-period of radium may be regarded as permanently radioactive. The radium spring waters, and "activated" waters from emanators and other devices are merely radon water, that is, they contain the short lived radioactive gas radon, which, like all other gases, dissolves in liquids

to a limited extent. These waters go dead in a few weeks unless they are continually reactivated.

A. Numerically, ingestion has been far more important than injection in producing victims of radium poisoning. Public⁴ and professional⁵ attention has been well focused on the tragic and horrible death of E. M. B. and several of his friends as a result of their drinking the radium water nostrum "Radithor."^{4, 5} For the first few months after taking radium into the body there is a sensation of well-being and general physical improvement. Soon, however, the deadly alpha ray bombardment of the blood producing centers begins to be felt, and death follows in a year or more, depending on the total quantity of radium fixed in the system. Protection of the public from these nostrums is mainly a matter of public health education and legislation.

B. Although the greatest number of victims came out of the luminous watch dial industry, this source has been quite well stopped by the introduction of machinery and of protective measures where hand work is still necessary. From the war period until the end of 1924 an average of some 350 persons, mostly women, were employed in hand painting luminous numerals and hands on watches, clocks, airplane instruments, etc. Due to labor turnover probably about 800 people worked long enough to endanger their lives. In painting the numerals on a fine watch, for example, an effort to duplicate the shaded script numeral of a professional penman was made. The 2, 3, 6 and 8 were hardest to make correctly, for the fine lines which contrast with the heavy strokes in these numerals were usually too broad, even with the use of the finest, clipped brushes. To rectify these too broad parts, the brush was cleaned and then drawn along the line like an eraser to remove the excess paint. For wiping and tipping the

brush the workers found that either a cloth or their fingers were too harsh, but by wiping the brush clean between their lips the proper erasing point could be obtained. This led to the so-called practice of "tipping" or pointing the brush in the lips. In some plants the brush was also tipped before painting a numeral. The paint so wiped off the brush was swallowed.

The luminous paint is a mixture of a gum binder, zinc sulphide, and enough radium, mesothorium-1, or radiothorium to give the required fluorescence. The mixture is about 1 part of radioactive material in 40,000 of paint.⁶ Depending on their skill, the workers tipped the brush from 1 to 15 times per dial, and painted 250 to 300 dials per day. A worker who licked 1 mg. of paint from her brush 4 times per dial, 300 dials per day, 5 days per week, would therefore ingest about 4,000 micrograms of radium in 6 months. When fixed in the bones, as little as 2 micrograms of radium has been fatal. Only rapid elimination of ingested radium, mainly in the feces, prevented prompt death.

C. Radium solutions have been used by some physicians in treatment of such ailments as gout, arthritis, cancer and leukemia. A fraction of the radium is deposited in the erythrocyte and leukocyte producing areas, and irritates these parts, with the result that there is an increase of both red and white blood corpuscles, and an apparent improvement in health. A period of overstimulation and then one of exhaustion may follow in which there is marked leukopenia and regenerative anemia, followed by fatal terminal infections. Apart from these effects on the blood forming apparatus, radioactivity has never been proved to be a specific therapeutic agent in internal medicine.^{7, 8, 9}

D. Those who, in hospitals, chemical or physical laboratories, or mines, handle radium solutions, make up radon

needles, or otherwise come in contact with radioactive dust or radon contaminated air, have been victims of fatal anemia in which radioactive substances were introduced through their lungs.^{7, 10}

E. Fortunately, most of the radium "activators" sold for treating drinking water contain far less radium than their vendors claim.³¹ So far as I know, no deaths have been traced to these devices; but in spite of years of trial, there is no controlled clinical evidence that this radon water is beneficial.¹¹ Those activators in which the water comes in contact with the radioactive source become dangerous when this material is appreciably dissolved in the water,¹⁰ for here one would be drinking radium water—not radon water. The better grade of "activators" will produce a radon concentration of 0.01 microcurie* per liter in water in 1 day, or 0.15 microcurie per liter in 1 month. As normally used, the water will have a radon concentration of about 0.1 microcurie of radon per liter, and also 0.0001 microgram of radium per liter.

EXIT OF RADIUM FROM THE BODY

The normal body throws off a large percentage of any radioactive material taken into it.

Where radon is breathed in, it remains in the blood only about 3 hours.^{10, 12, 13} Where radon water is drunk, the gas is carried by the blood to the lungs, where it passes out by diffusion and is soon lost from the body in breathing.¹⁴ The equilibrium distribution ratio (Henry's law constant) between blood and air at body temperature is between 0.42 and 0.31 to 1 by volumetric concentration.^{15, 16} During the few hours that radon is in the blood, about 1 or 2 per cent of it decays into the solid radioactive product

radium A, some of which is deposited permanently in the system and continues in the radioactive decay series until, after emitting 4 alpha and 4 beta particles per original atom of radon, it eventually becomes lead.

When radium is taken into the system it behaves in a manner similar to lead, being carried in the blood until it is either deposited as colloidal matter, principally in the bones, marrow, spleen, liver and lungs, or is excreted. After taking a soluble radium salt by mouth a much greater fraction is eliminated in the first 4 days than if it is received by intravenous injection.¹⁴ Thereafter the rate of elimination of radium is quite independent of the mode of entrance. According to the individual, from 2 to 35 per cent of the radium received by mouth remains in the system more than 5 days after ingestion,^{14, 17} while 55 to 65 per cent received by intravenous injection remains more than 5 days.¹⁴ By the 10th day after taking radium, the rate of elimination is below 1 per cent of the quantity remaining in the system. Several years after taking radium the rate of elimination is down to 0.002 to 0.005 per cent per day.¹⁷ At this low rate it would require about 45 years to eliminate half the radium in the system.

About 90 per cent of the radium eliminated is excreted in the feces, the remaining 10 per cent in the urine.^{14, 17} No radium is eliminated through the skin, as has been demonstrated by heavy sweating of a subject following an intravenous injection of 100 micrograms of radium.¹⁸ Although no radium can be exhaled in the breath, some radon does leave the system in this way, thereby relieving the body of the severe alpha particle bombardment from the decay products of radon. The fraction of the radon expired varies between the extreme limits of 2 and 40 per cent^{17, 19} of the total amount of radon produced in the body by the decay of radium.

* When radioactive equilibrium is present one curie of radon is associated with each gram of radium. Micro- = one millionth.

Efforts have been made to speed up the normal rate of elimination of radium. Martland⁷ tried without results to mobilize the radium deposits by intravenous injections of rapidly oxidizing colloidal solutions and by exposure of the body to ultra-violet light.

Aub found that a temporary acidosis, induced by the use of ammonium chloride, converted insoluble calcium and lead salts into soluble salts and expedited their excretion, particularly if the subject was on a low calcium diet. Following the original work of MacCallum and Voegthlin, and later of Collip, Aub²⁰ found that the injection of parathormone mobilized calcium and lead. Because the chemistry of calcium and radium is somewhat similar, Flinn and Seidlin²¹ inferred that advantage could be taken of this knowledge of calcium metabolism to speed up the normal elimination of radium. In 1929, 3 patients were each given parathormone every other day for a month, the dosage beginning at 10 units and working gradually up to 40 units per day. After a 2 weeks' rest, the treatments were continued, with 40 to 50 units injected every other day for 2 weeks. The 3 patients originally carried about 10, 20, and 40 micrograms of radium respectively; each patient lost about half of her radium during the treatment, gained weight and improved in general condition. One has since died of a brain tumor, the other 2 are still alive, but not in good health. Later, Flinn²² reported that 20 drops of viosterol given 3 times a day considerably hastened the elimination of radium. The mobilization of radium through calcium therapy seems at present to hold the only rational hope for the treatment of radium poisoning.

SYMPTOMS

In September, 1924, Dr. Theodore Blum, a New York dentist, reported²³ his belief that a case of osteomyelitis

of the mandible and maxilla, in a dial painter, which appeared similar to phosphorus necrosis, was in reality due to the action of radioactive substances taken into the mouth. The failure of the jaw to heal after the extraction of teeth, and the development of necrosis and osteomyelitis of the jaw is not only the condition which led to the first identification of radium poisoning, but remains today one of the first symptoms noticed in new cases.

The same symptoms are exhibited by victims of radioactive water nostrums⁵ and by dial painters.⁷ Symptoms may fail to appear until several years after the ingestion of radium has been discontinued. These facts lend weight to the belief that the jaw and mouth are slightly less resistant to radioactive bombardment than are other parts. Gingivitis, buccal infection, bone necrosis and osteomyelitis, low blood pressure, and regenerative anemias resembling true pernicious anemia are the most common symptoms of radium poisoning. X-ray examination will often disclose sharply circumscribed, nearly circular areas of rarefaction in the skull.²¹ Particularly in the cases which have long resisted the alpha ray bombardment of radioactivity, radiation osteitis and osteogenic sarcoma, often accompanied by slow-healing, spontaneous fractures, are quite generally present.²⁴

The occurrence of pregnancy is possible in victims of radium poisoning. The administration of ether anesthesia to victims of radium poisoning has been fatal in 3 cases.

For a more detailed discussion of the symptomatology of radium poisoning the reader should consult the excellent papers of Martland^{7, 24-28} and his co-workers.

Here it will suffice to point out that in cases where a radium history is suspected, the physician need never remain in doubt as to the presence of radium poisoning. Regardless of the presence

or absence of pathologic symptoms, the physicist offers at least 6 unambiguous physical laboratory tests for radium poisoning in living persons, only 2 of which (2 and 3 below) demand the presence of the patient in the laboratory.

1. Rapid and very sensitive, is the ionization-chamber-electrometer test of expired air for the presence of radon or thoron.^{7, 14, 19}

2. The gamma ray ionization-chamber-electrometer test for penetrating gamma radiation from the patient's body is widely used, and is best able to give a quantitative idea of the total amount of radioactive material contained in the system.^{7, 17, 19}

3. The Geiger point-counter and the Geiger-Müller tube-counter are sensitive, low pressure, electrical instruments which discharge when a radiation passes through them. When connected to a vacuum tube amplifier and a radio loud speaker they register as clicks in the speaker the number of quanta of radiation effective in them. Such an instrument placed near a victim's body will show a noticeable response to gamma radiation from the patient.

4. A small fraction (ca 0.005 per cent daily) of the radium in a victim is eliminated daily in the feces. Sensitive emanation electroscope methods^{17, 29} can be used for detecting radium in a solution of fecal ash. With proper apparatus, this method is extremely sensitive.

5. About one-ninth as much radium is eliminated daily in the urine as in the feces. Urine ash can also be tested by the emanation method.

6. Where a dentist has removed a tooth or a sequestrum from the jaw, radioactivity, if present, can easily be detected by at least 4 methods: the gamma ray ionization chamber, the Geiger or Geiger-Müller counters, the alpha ray emanation electroscope, or by self-photography due to the action of its beta and gamma rays on a photographic plate.^{5, 26, 39}

DISTRIBUTION OF RADIUM IN SYSTEM

Radioactive material tends to be phagocytized into the bones, marrow, spleen and liver. Because of its bearing on other heavy-element poisoning cases, the study of the distribution of radium in a victim of poisoning can be of considerable value. These can be carried out with some precision, because

radioactive quantitative analytical methods are over a million times as sensitive as ordinary inorganic analytical technic.

A total of from 2 to 180 micrograms of radium in the entire body has been measured in the fatal cases to date. Depending on the resistance of the individual's system, from 2 to 10 micrograms of radium, when fixed in the system, is a fatal dose.

The radioactive self-photographs of the bones of deceased victims show a lack of uniformity of distribution of radium.^{26, 30, 32} In some cases two or three small areas will be brilliantly self-photographic, while the remainder of the bone will display only a moderate amount of fairly evenly distributed radiation. This irregularity of distribution is important as an independent fact, as well as a warning that an analysis of a fragment chosen at random may not be representative of the entire bone from which it came.

Post-mortem radium analyses have been made on individuals who acquired

I. Diagnosis, Cancer of Uterus. One milligram radium injected Sept. 1, 1913. Autopsy held Dec. 17, 1913. The high radium content of the liver and other organs shows radium was still being fairly rapidly eliminated from the system.

II. Diagnosis, occupational poisoning, watch dial painter. Died Sept. 12, 1922. Body exhumed and autopsy held Oct. 15, 1927.

III. Diagnosis, poisoning from drinking radium water nostrum over a period of 5 years.

their radium by: (I) intravenous injection,¹² (II) dial painting,³⁰ (III) drinking radium water nostrums.⁵ The original data have been recomputed and are presented in Table I in a form which shows the *relative concentration* of radium in the various bones and organs before ashing them for analysis. For reference purposes the concentration of radium in the vertebrae, measured in grams radium per gram of bone, is taken as 100.

SUMMARY

Radium poisoning results when a few micrograms of radium or other alpha ray emitting solid radioactive substance become fixed in the system. Its action is principally to destroy the blood producing centers, and to weaken the bones. Calcium therapy, following Aub's and Flinn's work seems the only hope of removing radium from a victim's system. Modes of entrance of radium include the ingestion or breathing of radioactive substances by watch dial painters, chemists and miners, drinking radium water nostrums, and intravenous or other injections of radium by physicians.

From 60 to 98 per cent of the radium taken into the system is eliminated, principally in the feces (90 per cent) and urine (10 per cent). Some radon is lost in the expired air; no radium is lost in perspiration. Necrosis of the jaw, osteogenic sarcoma, and regenerative anemia are among the most common symptoms of radium poisoning. At least 6 unambiguous physical laboratory tests are available for identifying radium poisoning.

Mechanism of Infection in Poliomyelitis*

HAROLD K. FABER, M.D.

*Department of Pediatrics, Stanford University School of Medicine,
San Francisco, Calif.*

POLIOMYELITIS occupies a place of peculiar prominence among the acute infectious diseases which as medical men interested in the problems of public health and preventive medicine it is our task to control—for not only does it strike a special terror into the hearts of all parents but the recurrent epidemic waves appear to be rising higher and higher. We in California shall not soon forget the year 1930 when over a period of 7 months this plague spread from one end of the state to the other probably but little affected by our attempts at prevention or control.

There are not only many serious gaps in our understanding of epidemic poliomyelitis, but, I believe, some serious and widely accepted misconceptions as to the nature of the infection itself, particularly of the manner in which it enters the body, multiplies, invades and traverses the tissues and eventually produces its characteristic effects. Such faults must necessarily interfere with that clearness of thinking which is fundamental to any proper program of prevention, control and treatment.

Some of the questions that remain to be answered and that I wish to discuss are:

1. How is the virus of poliomyelitis conveyed to the human subject?
2. Exactly where is the anatomical site on

*Read before the Fourth Annual Meeting of the Western Branch of the American Public Health Association, Pasadena, Calif., May 30, 1933.

which, when deposited, it can effect an entrance to the interior of the body so as to "take"?

3. What channels does it follow—the blood, the lymph, the lymphoid structures, the nerves—in passing through the body to reach the ultimate goal where ordinarily it exerts its peculiarly disastrous effects—the anterior horns of the spinal cord?

4. Why in some cases does the disease fail to cause paralysis, and can such cases—presumptively as dangerous epidemiologically as those with paralysis—be detected, or are their symptoms frequently indistinguishable from those of other infections?

5. In what ways may we hope to improve the chance of effective control by prophylaxis and specific treatment?

1. That the virus of poliomyelitis is frequently and perhaps most commonly conveyed directly from one person who harbors it in the nasopharynx to another is a generally accepted belief which it is not necessary to question. That this is the only, or the only important, mode of convection there is some reason to doubt. Leaving aside such rare modes of transportation as milk, it seems clear that the simultaneous outbreaks of cases over widely scattered areas without known immediate contacts, the peculiar seasonal incidence during the warm and dusty months, the known resistance of the virus to drying and the probable portal of entry through the nose, all suggest a possibility of air convection in dust that deserves further investigation. This is a problem that has received much less consideration and direct study than it merits, although Neustadter and Thro,

in 1911, showed the presence of virus in the sweepings from a sick room. Dust transmission, while as yet unproved, might explain some obscure features in the epidemiology of poliomyelitis, and it is desirable that future research be devoted to the problem.

2. It is reasonably certain that the anatomical site of implantation and initial infection in poliomyelitis is the nasal mucosa, not the lower respiratory or the gastrointestinal tracts. Time is lacking to review all the evidence on this point, but it may be noted that: (a) the nasal mucosa is the only portion of the body surfaces where poliomyelitic infection can be produced with regularity and without trauma (Flexner has long upheld this view and recently Schultz and Gebhardt have reported "takes" in 43 out of 46 monkeys so treated); (b) other surfaces, such as the gastrointestinal, have been shown to be impermeable to the virus; (c) infection is accomplished with the utmost difficulty by way of the blood stream, only succeeding when enormous amounts of virus are introduced and only after a significantly delayed incubation period; (d) active virus has been detected on the nasal mucosa in patients with the disease, in carriers, and in 1 instance in a person who 5 days later came down with the disease.

The site of entry can be even more sharply delimited. It is obvious that the virus has a particular adaptation to nervous tissue and it is well established in experimental work that bringing virus into direct contact with nervous tissue is the only method reasonably certain to produce infection.

While the central nervous system is embryologically ectodermal there is only one situation in the mature vertebrate organism where it remains exposed on the very surface of the body and this is the so-called olfactory epithelium. Since this is probably the

area through which poliomyelitic virus enters the body, it may be noted that in the adult it is located high in the nose, in the superior meatus and the corresponding portion of the nasal septum, beyond the point reached by the air currents during quiet respiration, but that in the child it is relatively much nearer the external openings of the nostrils, a point that may have some bearing on the age incidence of poliomyelitis. By forcible inspiration and sniffing air is drawn directly over this area and material contained in the air deposited on the surface. Normally, most of the surfaces of the nose, especially in the middle and superior meatuses, are overlaid by mucus which moves downward and backward toward the nasopharynx under the influences of ciliary action, traction by swallowing, etc. The presence of the mucus and its movements are of the utmost protective importance in catching and removing particles of sputum and dust that may be inspired before they can reach and infect the mucus membranes themselves. The structure of the olfactory membrane renders it, moreover, particularly vulnerable to attack by a virus capable of infecting it, once this virus has been carried to its surface. The processes, the olfactory hairs, of the olfactory cells are by no means all embedded in the surface mucus but a large proportion of them actually lies free on the surface, directly exposed to the air—an arrangement essential to the sense of smell in all air-breathing vertebrates. Particulate matter carried by the air will then be deposited directly upon the long terminal processes of the olfactory cells, and if later embedded in the mucus will come in contact with the shorter olfactory hairs.

The possibility of exposure outlined takes on a particular importance when considered in relation with the known neurotropic properties of poliomyelitic

virus because the olfactory cells in the nasal epithelium, of which the olfactory hairs are essential parts, are in fact nerve cells connected by their axons directly with the central nervous system. The only direct communication between the nasal surface and the olfactory bulb is through the axons, or axis cylinders. Perineural lymphatics are probably not in immediate connection with the central nervous system but, if they do exist, communicate with the subarachnoid space, not with the bulb itself. There are no direct vascular connections between nasal mucosa and the central nervous system proper, and since the olfactory nerves are unmyelinated there is no communication even through myelin sheaths. These points, as well as others to be mentioned later, are of particular importance in relation to the experiments of Fairbrother and Hurst and of Hurst, which demonstrated a fundamental principle of poliomyelitic infection; namely, that the virus is propagated along and through the axons of the nervous system. The normal anatomy of the olfactory mucosa and nerves, therefore, is seen to offer a direct channel for a virus with the known properties of that of poliomyelitis, to ascend directly from the surface into the very substance of the central nervous system.

Can such ascent in fact be demonstrated? In 1912 Flexner and Clark swabbed the surface of the nasal mucosa in a monkey with a suspension of poliomyelitis virus; 48 hours later, they killed the animal and found virus present in the olfactory bulb but not—and this is important—in either the medulla or the spinal cord. They drew the justified conclusion that the virus had ascended through or along the olfactory nerves to the bulb and had not spread through the blood or cerebrospinal fluid, else the more susceptible medulla and spinal cord would have become simultaneously infected. By reason of

technical difficulties this experiment appears not to have been repeated. Recently, however, with Gebhardt's assistance, I was able to confirm and amplify the result. On the fourth day of incubation, when virus was first demonstrated in the central nervous system, it was strictly limited to the olfactory bulb and was not found in the brain stem, cerebral cortex, pons, medulla, spinal cord or dorsal ganglia. In the olfactory bulb, however, it was present in a very high concentration. It seems fair to conclude that *the olfactory bulb is the initial focus within the central nervous system of poliomyelitic infection.*

3. The next question is what pathways the virus follows in reaching out toward the spinal cord where it produces its most characteristic end effects. Is it through the blood stream, through the cerebrospinal fluid, or through the substance of the nervous tissues? If through the blood stream we should during the ensuing days of the incubation period find the virus evenly distributed through the central nervous system, or at least through the highly susceptible medulla and spinal cord. If through cerebrospinal fluid the spread should be similarly diffuse and rapid, since the circulation of this fluid to all levels of the central nervous system is rapid, as shown by familiar experience with dyes, and infectious material introduced into the cerebral subarachnoid spaces would reach the spinal spaces within a few minutes. If spread is through the axons it should be much slower and virus should be found successively, during the incubation period, in the central ganglia, medulla and cord, since it is by these paths that the outgoing tracts of the olfactory system connect with other portions of the central nervous system. The localizations of virus on the fifth, sixth and seventh days, as determined in our experiments, did, in fact,

correspond closely with the axonal route postulated, and no virus was found in the spinal cord until the seventh day. Moreover, no virus was found even in the cerebellum, on only one occasion in the cerebral cortex and then, on the seventh day, in the olfactory region of Ammon's horn. The experiments, then, show that virus is propagated along the axons rather than in the cerebrospinal fluid (as had been shown by Fairbrother and Hurst) and, in the laboratory animal at least, along a particular route through the olfactory nerves, bulb and tracts and thence through connecting tracts to the medulla and cord, avoiding the cerebral cortex and cerebellum.

What reasons are there to believe that the same route of propagation holds true for human infection? First, the portal of entry appears to be the same. Second, as shown by various pathologists (Harbitz and Scheel, Müller, Wickman and others) the distribution of lesions in the brain and brain stem closely corresponds with the route described—an abundance of lesions in the central ganglia, midbrain, medulla, with few, slight or no lesions in the cerebral cortex and cerebellum. Third, the early symptomatology of the disease, as was suggested many years ago by Redlich, is strongly suggestive of a central nervous origin. Moreover, a careful analysis of the onset and later pre-paralytic symptoms which I have recently made, shows that the very first manifestations of poliomyelitis may well originate in the upper portions of the brain stem which are directly connected with the olfactory tracts, while the subsequent signs and symptoms apparently originate in the medulla, posterior horns of the cord and dorsal ganglia with final implication of the anterior horns. Thus, the clinical manifestations not only harmonize with the animal experiments as evidence of spread of the disease solely within the central nervous

system, but supplement them by showing the pathways followed by the infection within the spinal cord itself.

4. The non-paralytic, so-called abortive type, of poliomyelitis is of much theoretical interest and even greater practical importance, especially to the epidemiologist and clinician. This type of case is explained by the failure of the virus to complete its journey to the anterior horn cells of the cord or to die out before it has lethally infected them. Since this occurrence is but rarely noted in monkeys the experimental study of the subject is difficult, though the tendency for the virus to die out in areas of the brain previously infected has been noted by Fairbrother and Hurst, and was also evident in our experiments of the 7th day. From a practical standpoint, interest focusses on the frequency of abortive cases in man and the possibility of detecting them with regularity and reasonable certainty, particularly because it may be supposed that such relatively mild cases afford, especially if ambulant, means for the spread of contagion. The frequency of such cases has by some been estimated as high as 10 to 1 in relation to those with frank paralysis, and it has often been thought that during or preceding epidemics many very mild illnesses, characterized by slight fever, mild respiratory or gastrointestinal disturbances, and presenting no pathognomonic features of poliomyelitis are in fact mild and unrecognizable forms of that disease. This conception, which during epidemics has led to a considerable amount of apprehension and hysteria in the minds of the lay public, has no very convincing factual basis. Though varying considerably in different epidemics, the ratio of non-paralytic to paralytic cases is probably on the average not more than 2 or 3 to 1. More important, it is now exceptional for cases of poliomyelitis to fail of diagnosis. The

increased familiarity of the medical profession with the disease and its alertness for early diagnosis are responsible for this. The studies of Aycock and his associates in Massachusetts showed few missed cases, and that minor infections occurring during an epidemic period of poliomyelitis could not be shown to have been mild poliomyelitis by subsequent tests for immunity. It is only in very exceptional cases, non-paralytic as well as paralytic, that the first lumbar puncture fails to reveal characteristic changes. Moreover, it is becoming increasingly clear that the early clinical picture of poliomyelitis is characteristic, generally recognizable and essentially identical in the cases that go on to paralysis and in those that end without it.

The very existence of abortive cases and their occurrence in considerable numbers point to a fact that is little appreciated; namely, that the virus of poliomyelitis is, on the whole, rather poorly adapted to survival in man, or, to put it another way, that the great majority of human beings possess very considerable powers of defense against it.

The course of the disease even in patients who have some residual paralysis supplies further evidence of this fact, since in the average case only a few restricted areas of motor cells in the cord or medulla are destroyed and the rest are either unaffected at all, or, if affected during the acute phases of the disease, recover their function completely, as shown by diminution of the extent of paralysis; moreover complete recovery of the sensory cells, almost always involved early in the disease, is practically uniform when the patient survives. The fact that about 80 per cent of urban adults possess specific immune serum antibodies against poliomyelitis must indicate that they at one time harbored the virus and resisted its effects.

5. This obvious fact of poor adaptability of the virus to human tissue or of effective defense against its attack offers at the same time a basis for some optimism in regard to the possibilities of prevention, if not of treatment. If the virus tends in the average case to die out quickly, cannot this tendency be increased by artificial means before or during the actual attack? The hopes and disappointments of serum therapy in poliomyelitis are familiar to all. At present there is widespread pessimism over the value of convalescent serum, based in part on the results of experimental work and in part on clinical observation. In the monkey, it is apparently impossible to prevent the disease from developing or even to modify its course by the administration of immune serum very long after inoculation of virus into the brain or even on the nasal mucosa. It is, however, only fair to point out that poliomyelitis is a much more severe infection as a rule in the monkey than in man, leading almost regularly to complete paralysis and death; whereas in man the average mortality is only 15-20 per cent; not over half of the total cases show residual paralysis and in the majority of these a relatively small proportion of the total muscle mass is involved. It might be expected *a priori* that the administration of serum would still further lessen the incidence and extent of paralysis in treated patients and this was apparently shown by the studies of Aycock and Kramer in the Massachusetts epidemic of 1929, and by Amoss in a subsequent study. More recently Kramer and his associates, and Park and his associates, have cast serious doubt on the occurrence of any beneficial results from serum, by their clinical comparisons of treated and untreated cases in the same locality and period of time. Nevertheless, I believe that judgment may be suspended until further trials have been made. My

reasons for this are that the sera generally used have been of unknown, and probably in many cases, defective strength in respect to the concentration of antibodies, and that the amounts used and the methods of administration may often have been seriously inadequate. The convalescent from poliomyelitis does not necessarily show a high degree of specific immunity in his serum; in fact, there is reason to believe that it is not infrequently low and that, in some instances, he originally acquired the disease because of an inherent inability to form antibodies in normal amounts. Individuals who have never had manifest poliomyelitis may have much higher concentrations of immune substances in their serum. The situation might be compared with that in the treatment of diphtheria if the only antitoxin used had been of untested, unknown titer, employed in inadequate amounts. In poliomyelitis it is possible to make a more convincing test of therapeutic value than has hitherto been developed, by using as donors only those individuals—preferably adults—who, irrespective of previous poliomyelitis, are known by specific test to have highly immune blood; thus overcoming the restrictions of serum supply that are incidental to the exclusive use of convalescents, most of whom are young children. A perhaps more promising source of really potent serum has been made available by the discovery that some horses and other animals can be immunized to a very high degree—much higher than any observed in man—and so provide therapeutic serum in large amounts. The value of really intensive therapy still remains quite problematical. Park assumes that once the virus has lodged within the nerve cell it is inaccessible to the circulating antibodies. This is probably correct but I have elsewhere pointed out that for poliomyelitic infection to run its full course to lower

motor neuron paralysis it is necessary for virus to escape from an infected cell, to traverse the synaptic space between it and the next neuron and in this space to be exposed to the interstitial fluids, which presumably contain immune substances derived from the blood stream. For this theoretical reason, a thoroughgoing trial of really intensive serum therapy is worth making.

The chances of effective prophylaxis in poliomyelitis are in some respects at least hopeful. It is true that no safe or certain method of active immunization, even in the experimental animal, has as yet been developed, despite long continued, energetic and extensive study by many investigators. Nevertheless, the results of some of the virus modifications and of intracutaneous inoculation afford a basis for encouraging further study. The curious fact that subinfective inoculations into nerve tissue give no immunity suggests that immunity, or at least the production of immune virucidal substances in the serum, is the result of an extranevous reaction to the virus rather than of actual, subclinical infection. If this be true, the prospect of eventually developing a safe and effective method of active immunization appears to be distinctly hopeful. While active immunization is at present a hope rather than a reality, passive immunization as a means of preventing infection during epidemics appears to be already of practical, if limited, importance. It is known from experiment, that animals can be protected for a time from the effects of virus inoculation by the preliminary or simultaneous injection of immune serum, and in human beings it appears to be well authenticated that passive protection to another virus disease, measles, is practicable. Even though passive protection from the injection of immune serum in general appears to last only a few weeks, such protection is decidedly worthwhile. The use of

convalescent or normal serum (from parents or others) for this purpose has been carried out on a fairly large scale in Pennsylvania, in the epidemic of poliomyelitis, 1932, with apparently beneficial results, and I believe that we are no longer justified in reserving immune serum for exclusive use in treatment of patients who have already developed the disease. Here again, I strongly urge the use of tested serum, known to contain virucidal substances in substantial concentrations. This will require organization and financial support in advance of epidemics, since, for passive immunization, human serum is decidedly preferable to that of horses or other animals in order to minimize sensitization. It is perfectly feasible to test potential donors in sufficient numbers to provide an adequate supply of high grade human serum for any given community, since it has been

shown that about 80 per cent of normal adults have specific immune substances in their blood, and of these a very considerable percentage have them in reasonably large amounts. This is a matter which state and municipal boards of health should look into with a view to obtaining adequate appropriations. There is no disease over which the public is more apprehensive and in which both the laity and medical profession feel more helpless, and I believe that an effort to supply any promising method of defense would meet with prompt public support.

NOTE: References, here omitted, as well as the analysis of symptoms and other matter referred to in this paper will be found in a review by the author that appeared in *Medicine*, May, 1933. The experiments by Faber and Gebhardt are reported in detail in the *Journal of Experimental Medicine*, June, 1933.

Destruction of the Vitamins by Pasteurization

THE only vitamin which has been shown to be destroyed by pasteurization is vitamin C, and the destruction is only partial. The only disease due to a vitamin deficiency, which has been shown to be associated with the use of pasteurized milk, is infantile scurvy. This disease results from a deficiency of vitamin C, and in some of the cases reported the cause was traced to the use of milk which had been pasteurized more than once. However, even on complete diets of efficiently pasteurized milk, the danger of mild scurvy must be considered to exist, and diets for children should always be supplemented by other sources of the anti-scorbutic agent, e.g., orange juice. This practice is wide-spread today, but it is not gen-

erally recognized that any ordinary bulk milks, whether raw or pasteurized, represent comparatively poor and variable sources, not only of vitamin C, but of certain other vitamins. Under these circumstances there is considerable force in the argument that dependence on complete milk diets as efficient vitamin sources should be discontinued. The merit of including raw milk in the diet of young children for the prevention or arrest of dental caries has been demonstrated, but the contention that pasteurized milk is not an efficient agent has been shown to be unproven.—The Nutritive Properties of Milk in Relation to Pasteurisation. J. D. Stirling and J. H. Blackwood. Hannah Dairy Research Institute, *Bull.* 5, p. 71.

Natural and Induced Variations in the Vitamin Values of Milk*

H. C. SHERMAN

Department of Chemistry, Columbia University, New York, N. Y.

THE mammals which man has domesticated, and whose milk is now largely diverted to purposes of human nutrition, have doubtless played a large part in so nourishing the human family as to permit of its evolving a type of life-cycle which provides liberally for mental and social development.

Doubtless what some evolutionists have called the "prolongation of infancy"—perhaps more clearly expressed as an extension of the learning period to occupy a larger part of the life-cycle of the individual member of the race—has probably been largely dependent upon the use of milk in human nutrition to a greater extent than was or is possible through human milk alone.

Thus there is a very far reaching significance in our employment of cows' milk as human food, and in the questions: How constant is this food in the various aspects of its nutritive value? How far have the different factors of nutritive value in milk been stabilized by evolution? How far can we control or improve them through our treatment of the cow which produces the milk or of the milk itself after its production?

These are large and somewhat complex questions. The need for brevity in this paper makes it seem wiser to treat them in somewhat general (even if sketchy) terms, in the hope of making

clear the main principles involved, rather than to attempt a technical analysis of the experimental details with citations of original publications.

VITAMIN A

McCollum and Simmonds early showed that the vitamin A value of milk depends ultimately upon that of the food which the lactating female has received. That the vitamin A content of milk may be raised by the feeding of cod liver oil, kale, or fresh pasture has been shown by Drummond, Coward, and Watson; Kennedy and Dutcher; Golding and Luce; and Golding, Soames, and Zilva. On the other hand Fraps and his coworkers have shown that a cow previously well fed may supply vitamin A to her milk from her bodily store to such an extent that the fat of her milk continues to be of normal vitamin A value during many months of subsistence on a diet poor in vitamin A. MacLeod, Brodie, and Maclooin found that milk produced under good and substantially uniform conditions of stall feeding was of practically the same high vitamin A value throughout the year. The Nebraska Agricultural Experiment Station reports that the vitamin A values of the milks of different breeds of cows do not differ as do the percentages of fat in these milks.

Undoubtedly the vitamin A of the mother's milk has important survival value for the species. This fact and such experimental findings as have just been briefly noted both support the view that evolution has in some measure

* To be read at a Joint Session of the International Association of Dairy and Milk Inspectors and the Food and Nutrition Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1935.

stabilized the vitamin A content of milk, and that it has further provided for the maintenance of relative constancy in this regard by the development of the body's capacity to store vitamin A in relatively large amounts in times of abundant intake and to furnish vitamin A to the milk from this store during periods when the intake is low.

In view of the great importance of vitamin A for growth and healthy development, it is natural to find that the mammalian species have evolved the capacity to transfer rich stores of this vitamin to the milk whose sole function in nature is to serve as nutriment. And as cattle are furnished with a digestive apparatus which permits them to consume grasses and other leafy foods in very large amounts, and they have been bred to high efficiency and capacity in milk production, the milch-cow performs a most important service in bringing into form favorable to human consumption and utilization liberal supplies of vitamin or pro-vitamin A which have been formed in the green leaves of plants.

This fact, and the stabilizing influence of the factor of body storage, and the further fact that the rations which are economically profitable for the dairy farmer to feed are almost always of fairly high vitamin A value—all combine to bring about the result that under present-day conditions of actual practice the vitamin A value of ordinary mixed whole market milk is fairly uniform so that milk is both a highly important and a highly reliable source of vitamin A.

VITAMIN B

Recent research by Steenbock and his coworkers indicates that the vitamin B content of milk is "under physiological control" in the sense that it cannot readily be raised above a normal value by the feeding of more vitamin to the

cow; and also in the sense that when this factor in the milk has been artificially lowered by the feeding of rations very poor in vitamin B, the normal vitamin B value of the milk is quickly regained as soon as the cow is again normally fed.

Here, as in the case of vitamin A, the rations which are found profitable in modern milk farming are sufficiently rich in the vitamin to make it fairly certain that milk made on such rations will predominate in the mixed milk which appears in the market under present-day conditions.

The striking results obtained at the Pennsylvania Agricultural Experiment Station show also that the digestive tract of the cow furnishes a favorable environment for certain vitamin-B-producing bacteria, so that a cow may continue to produce milk of normal vitamin B value even when her food is rendered abnormally poor in this vitamin for a long experimental period.

Thus, while milk is not an outstandingly rich source of vitamin B, it now appears to be a more constant and reliable source than has hitherto been appreciated.

VITAMIN C

What has just been said of vitamin B, is true also of vitamin C: milk is not a rich source of this vitamin, but is a more reliable source than is generally understood. Also milk and potatoes are typical of the foods which while having only relatively low concentrations of vitamin C are yet important sources of this vitamin because of the relatively large amounts in which these foods are consumed in an ordinarily well balanced American or European dietary.

Several years ago it was shown by the work of the Minnesota and Wisconsin Agricultural Experiment Stations and by that of Dr. Hess of New York City that the vitamin C value of milk

can be decidedly influenced by the feeding of the cow. These experiments were of fundamental importance but may have given rise to exaggerated impressions. Seeking clear-cut and conclusive results, the experimenters made use of rations differing more radically than is common in actual practice, and correspondingly they found larger differences in the vitamin C values of the milks produced than are apt to be found among the milks that ordinarily come to market.

Repeated tests at the Kansas Agricultural Experiment Station indicated a better maintenance of the vitamin C value of the milk even when cows were kept for long periods on vitamin-C-poor food. Whether there is a possibility of synthesis of vitamin C by bacteria in the digestive tract of the cow, as noted above in relation to vitamin B, remains to be determined.

MacLeod found that with good feeding such as modern dairy farmers already use in the interest of high milk production, the milk as sent to market by a large dairy farm in New Jersey was of practically constant vitamin C value throughout the year, and that this value is about 50 per cent higher than the estimates current in the literature would indicate.

Thus while there have undoubtedly been valid demonstrations of wide variations of vitamin C values of milk as induced by experimental feeding, the present evidence indicates strongly that such differences need not occur at any season of the year under the ordinary conditions of dairy farming, and need not be anticipated in the mixed market milk ordinarily delivered to consumers under present-day conditions.

VITAMIN D

Hitherto, the methods generally used in testing for vitamin D values have involved the employment of experimental diets of such drastically rickets-

producing character that only relatively high antirachitic potencies could be demonstrated. With the use of more delicate or of more searching methods, it is now being found that several foods including milk are more important sources of vitamin D than previous work had indicated or than would be inferred from the statements still current in the literature.

However, in northern latitudes and in cities where the antirachitic value of sunlight is greatly diminished by smokiness of the atmosphere, it is to the advantage of the human infant (and perhaps of older humans as well) to receive more vitamin D than cows' milk as hitherto commonly produced can be depended upon to supply—hence the present interest in methods for the enrichment of the vitamin D value of milk.

A large amount of evidence now consistently indicates that this idea is scientifically and economically sound, and so distinctly to the advantage of the public health as to be worthy of encouragement and practical extension even during the period in which some of the methods of official control still remain to be developed.

Three different methods of enrichment of milk in vitamin D—(1) the direct addition of a vitamin D concentrate, (2) the irradiation of the milk, and (3) the feeding of irradiated yeast or other suitable irradiated material to the cow—have all been shown to be practicable and effective. As all of these methods were ably discussed in papers presented at the Washington meeting, it is not necessary to discuss them further here. All seem certainly to be meritorious; their relative merits will doubtless become clearer with further investigation and experience.

The fourth method which naturally suggests itself, namely, the irradiation of the cow, has thus far yielded rather conflicting evidence. Among the most

recent findings, those of Mitchell, Eiman, Whipple, and Stokes (reported at the Washington meeting and published in the *Journal* of December, 1932) seem on the whole to be encouraging.

Hence those who desire to secure and insure the enrichment of milk in vitamin D have a choice, certainly of three and perhaps of four, practicable methods. Even though this situation presents problems as to methods of official regulation, it is highly gratifying as an advance in the practical campaign for the eradication of rickets, and for insuring the public a milk supply of high and well balanced vitamin value.

VITAMIN E

For two reasons this paper does not attempt to summarize the case for vitamin E in parallel fashion with that of the other better known vitamins: (1) there seems to be no convincing evidence as yet that vitamin E is a practical factor in human health; and (2) methods for the quantitative measurement of the vitamin E values of foods have not been developed and standardized to the same degree as in corresponding work with the other vitamins here considered.

VITAMIN G

The differentiation of vitamin G (B_2) from vitamin B (B_1) is so recent, and the methods for the measurement of vitamin G values have even yet been adequately controlled in so few laboratories, that the extent and causes of variation of the vitamin G value of milk are probably best regarded as problems still awaiting precise quantitative development.

We have, however, considerable evidence that milk as ordinarily produced is a rich and reliable source of vitamin G at all seasons of the year. It is to be hoped that means can soon be found for such further quantitative research

in this field as is needed to give greater precision and positiveness to our knowledge, for vitamin G is undoubtedly very important to public health and individual efficiency.

SUMMARY

While the vitamins differ too much among themselves, in chemical nature and in nutritional function, to permit of much generalization, the chief principles involved in the facts above summarized may be briefly recapitulated as follows:

1. The animal organism is not to be expected to synthesize vitamins *de novo* in the same sense that it synthesizes enzymes and hormones. In general, either the vitamin or its precursor must be furnished by the food or some other factor of the environment, such as symbiotic bacterial action in the case of vitamin B or irradiation in the case of vitamin D, must be provided.
2. The fact that the ordinary environment of the cow does provide such factors makes the vitamin values of market milk somewhat less dependent upon the vitamin values of the food of the cow in actual practice than has appeared to be the case in those researches in which artificially drastic conditions were set up and maintained for experimental purposes. In the case of vitamin A bodily storage also serves to regulate the vitamin value of the milk.
3. A further regulator of the vitamin value of milk as practically produced for market is found in the fact that the rations which are profitable for the dairy farmer to feed are not at any time of the year apt to be vitamin-poor; and if vitamin-poor rations are occasionally fed they do not produce a large enough amount of milk to influence seriously the nutritional character of the mixed milk which comes to market under the present-day conditions and methods of the milk industry.
4. In the one case in which this is less true than in the others, and in which therefore there is special reason for the fortification of the milk, namely with vitamin D, there are certainly three and perhaps four different practicable methods by which the desired enrichment may be accomplished.
5. In the vitamin G value of milk we have a recently discovered factor, of much importance in nutrition and food values, the precise evaluation of which must await further and more far reaching research.

Toxic Amblyopia and Accompanying Physiological Disturbances in Carbon Tetrachloride Intoxication*

ZOLTON T. WIRTSCHAFTER, M.D.
Cleveland, Ohio

TOXIC amblyopia is an ocular condition, characterized by dimness of vision and an alteration of the color fields, the etiological factor being, in most cases, a substance of exogenous origin.

In his discussion of toxic amblyopia due to carbon bisulphide intoxication, Knapp¹ states:

... the patients complain of seeing through a cloud; there is the characteristic central disturbance of vision with a comparatively free periphery of the field and the loss of color perception in the center. The condition is usually bilateral and all the reports agree on the presence of the central defect with normal periphery of the field, characteristic for toxic amblyopia in general.

In the present study of toxic amblyopia due to carbon tetrachloride poisoning, perimetric examination revealed no central defect but a marked constriction of the periphery of the visual color fields. The subjective symptom of dimness of vision, however, was the same as in the usual toxic amblyopia as typified by carbon bisulphide poisoning.

OBSERVATION OF CASES

Five adult male workers from four establishments in the dry cleaning industry were examined. All of these men were exposed to carbon tetra-

chloride vapor from 8 to 10 hours daily for periods varying from 1 to 6 months preceding examination.

Case 1—J. L., a white male, age 20, had been exposed for a period of 5 weeks previous to examination. He complained chiefly of severe frontal headache associated with vertigo, tinnitus, nausea and vomiting. He was unable to eat without subsequently vomiting most of the ingested food. These symptoms started within a few days after commencing this work. About 3 weeks after exposure began, he noticed a gradually increasing disturbance of vision, manifested by seeing "spots before the eyes." He also complained of a marked disturbance of the sense of taste, so that "even cigarettes tasted like bile." Physical examination revealed a well developed white male, weight 218 lb., appearing somewhat lethargic and stuporous. There was moderate pallor of his skin. The sclerae had a slight icteric tinge. The pupils were normal and reacted normally to light and accommodation. Heart and lungs were normal. Abdominal examination was normal. Reflexes were physiological. Blood sugar tolerance analyses were as follows:

| | Blood Sugar | Urine Sugar |
|---------|-------------|-------------|
| Fasting | 87 mg. | Slight |
| 30 Min. | 154 mg. | None |
| 1 Hr. | 115 mg. | Trace |
| 2 Hr. | 99 mg. | None |
| 3 Hr. | 90 mg. | None |

* To be read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

Case 2—F. K., a white male, age 43, had been exposed to the carbon tetrachloride vapors for a period of 10 weeks previous to examination. Before the period of exposure he had been in good health. Since working at the dry cleaning plant, he had had continual nausea but did not vomit. The nausea was accompanied by marked dizziness, headache, and weakness. He suffered no pain of any kind. About 2 weeks after commencing work, his vision became blurred and his eyes felt greatly irritated. In addition to the above complaints, there was marked polyuria and constipation. Physical examination showed a well developed white male, weight 165 lb., appearing somewhat weak and lethargic. The conjunctivae were congested and there was marked epiphora. Heart was normal. They were a few moist râles at both lung bases. The abdomen was normal. Reflexes were normal. Blood sugar tolerance analyses were as follows:

| | Blood Sugar | Urine Sugar |
|---------|-------------|-------------|
| Fasting | 90 mg. | Slight |
| 30 Min. | 169 mg. | Moderate |
| 1 Hr. | 150 mg. | Large Amt. |
| 2 Hr. | 84 mg. | Mod. |
| 3 Hr. | 61 mg. | Slight |

Case 3—H. M., a white male, age 30, had been exposed for a period of 4 weeks previous to examination. During this period he had severe diarrhea with moderate abdominal pain. Two weeks after the onset of the exposure nausea and vomiting began. The vomiting occurred about 15 minutes after each meal, being most marked after the noonday meal. In the period after the onset of the gastric symptoms he lost 6 lb. in weight. He complained of increasing muscular weakness and lassitude. Physical examination revealed a well developed white male, weight 146 lb., appearing markedly irritable. There was marked skin palor. The conjunctivae were

congested and there was marked epiphora. Heart, lungs and abdomen were normal. There was slight exaggeration of the abdominal reflexes and also a slight tremor of the hands. Blood sugar tolerance analyses were as follows:

| | Blood Sugar | Urine Sugar |
|---------|-------------|-------------|
| Fasting | 90 mg. | Slight |
| 30 Min. | 118 mg. | None |
| 1 Hr. | 95 mg. | Slight |
| 2 Hr. | 89 mg. | Slight |
| 3 Hr. | 80 mg. | Slight |

Case 4—R. V., a white male, age 48, had been exposed for a period of 6 months before examination. He complained of severe dizziness, headache, nausea, and vomiting. The ocular symptoms in this case were more marked than in any of the others. He stated that everything looked smaller than previously; that he had black spots before his eyes continually. The dimness of vision became so marked that on several occasions while driving his automobile home from work, he had to stop for a few minutes until his vision cleared slightly before he could proceed further. At the time of examination he had ceased driving. Physical examination revealed a well developed white male, weight 207 lb. The skin showed slight pallor. The pupils reacted normally to light but more slowly to accommodation. Heart, lungs, and abdomen were normal. Reflexes were normal. Blood sugar tolerance analyses were as follows:

| | Blood Sugar | Urine Sugar |
|---------|-------------|-------------|
| Fasting | 78 mg. | Slight |
| 30 Min. | 150 mg. | Moderate |
| 1 Hr. | 124 mg. | Large Amt. |
| 2 Hr. | 90 mg. | Slight |
| 3 Hr. | 74 Mg. | Slight |

Case 5—I. H., a white male, age 44, had been exposed for 6 weeks before examination. He observed no symptoms until about 3 weeks after he began to work over the vats. He then began

to have nausea and headache but did not vomit until about 1 week later when the vomiting became very severe. At this time he was unable to retain any food in his stomach. The attacks of vomiting were accompanied by severe abdominal cramps. He also had attacks of diarrhea which varied in severity. He stated that for the past few nights he had been unable to sleep, although he felt sleepy and tired. During the period of exposure there had been a gradual but complete loss of sexual libido. During this period he lost 9 lb. in weight. Physical examination showed a well developed white male, weight 156 lb. The conjunctivae were congested and there was slight epiphora. Heart, lungs, abdomen and reflexes were normal. Blood sugar tolerance analyses were as follows:

| | Blood Sugar | Urine Sugar |
|---------|-------------|-------------|
| Fasting | 96 mg. | None |
| 30 Min. | 124 mg. | Moderate |
| 1 Hr. | 116 mg. | Slight |
| 2 Hr. | 95 mg. | Slight |
| 3 Hr. | 90 mg. | Slight |

Ophthalmoscopic examination in these cases did not reveal any abnormalities except a slight paleness of the disc. Toxic amblyopia being suspected, perimetric examinations of the five men were made. All of the men, including the two who had not suffered from visual disturbances, showed bilateral peripheral constriction of the color fields. No central scotomata were present in any of the perimetric charts. A B&L Stereo-Campimeter was employed in making all central field studies. Peripheral fields were checked up with a campigraph. Illumination in all cases and the size of the test object ($1\frac{1}{2}^\circ$) were kept constant. A uniform procedure of examination was employed in all cases, targets being moved from non-visible to visible. Periodic observations in Case 1 illustrate the

progress of a typical case. With the removal of exposure, the subjective visual disturbances as well as the general complaints disappeared. At intervals of 7 to 10 days, perimetric examinations were repeated, and revealed a gradual expansion of all the color fields which were found to be within normal limits 5 weeks after cessation of exposure.

PATHOLOGICAL PHYSIOLOGY

The pathological physiology of the toxic amblyopia observed in carbon tetrachloride intoxication appears to be closely associated with disturbances in carbohydrate and fat metabolism. Lamson² states that "carbon tetrachloride produces a liver necrosis with an increase of guanidine or guanidine-like substances in the blood with a subsequent fall of blood sugar." In this group of cases, the men had blood glucose concentrations which were at the lower border of the normal variation and, in some cases, even below this. Moreover, slight amounts of sugar were found in the fasting urine specimens and larger amounts after the administration of glucose, especially in Case 2. The blood sugars, urines, and the visual fields returned to normal after the men left their work and were put on a high calcium and dextrose diet. This therapy has been used in carbon tetrachloride poisoning by many investigators including Minot and Cutler.³

Recently, Adler⁴ has demonstrated that that portion of vitreous humor of the eye which is in close contact with the retina contains less sugar than the more anterior layers. This was shown to be due to the fact that the retina has a greater glycolytic power than any other tissue of the eye, *i.e.*, the low sugar content of the vitreous is a result of the rapid utilization of glucose by the adjacent retina. All sugar entering the vitreous must first pass through the

retinal circulation, where a portion of it is consumed. Adler further demonstrated that sugar could not pass into the vitreous from the aqueous humor. He suggests that "possibly the retina, not having storage facilities for glycogen, is forced to use the glucose circulating in the blood for its metabolic need."

A lipemia and a cholesterolemia have been shown to be present in carbon tetrachloride poisoning as a result of central necrosis and fatty degeneration of the liver. MacMahon and Weiss⁵ report an autopsy in a case of severe carbon tetrachloride poisoning in which the blood in the pulmonary arteries contained 64 per cent fat and in the inferior vena cava 25 per cent. They state that the source of the fat was the liver which showed severe injury. Butsch⁶ reports a non-fatal case of carbon tetrachloride intoxication in which the blood fat on admission was 1,245 mg. per 100 c.c. estimated as tripalmitin, but which dropped to 765 mg. 3 weeks later. The serum cholesterol in this case was 856 mg. per 100 c.c. on admission and 563 mg. after 3 weeks. The patient was back at work 1 month after admission to the hospital.

According to Adler,⁴ "there is clinical evidence that some substance present in the liver and in certain fats is concerned with rod-visual purple function." The periphery of the retina consists chiefly of rods, and, moreover, the visual purple is most abundant in this area. The scotomata which occur as a result of disturbances of the outer layer of the retina, which includes the rod-visual purple mechanism, correspond in "position, shape and extent to the retinal lesion."

Whatever theoretical explanation these facts may have, it is suggested that (a) as a result of the low blood

sugar which is encountered in carbon tetrachloride intoxication, the retina is deprived of an adequate source of glucose, a constant supply of which is essential to the normal metabolism and function of the retina; (b) that another factor in the visual disturbance may be an alteration of the rod-visual purple mechanism of the periphery associated with the deranged fat metabolism.

Although the constitutional symptoms in the present series of cases were not especially severe, the constriction of the color fields was marked even in the mildest case. It is of utmost significance that carbon tetrachloride intoxication can be detected at an early stage by routine perimetric examination of exposed workers. It is probable that similar phenomena may be discovered by the same method in intoxications caused by other fat solvents, such as chloroform or benzol.

CONCLUSIONS

1. Toxic amblyopia may result from exposure to carbon tetrachloride vapor.
2. The resulting amblyopia is characterized by concentric constrictions of all the color fields without central scotomata.
3. The resulting amblyopia differs from the usual toxic amblyopia, of which that due to carbon bisulphide is typical, in that the color fields in the latter are marked by central scotomata with a normal periphery.
4. With cessation of exposure, and a high calcium and dextrose diet, the amblyopia rapidly disappears.
5. Routine examination of the visual fields of workers exposed to the vapor of carbon tetrachloride is suggested to detect intoxication at an early stage.

"Food-Poisoning"—A Public Health Problem*

J. C. GEIGER, M.D., F.A.P.H.A., AND J. P. GRAY, M.D.

Department of Public Health, San Francisco, Calif.

FOOD-POISONING—as it is understood today—is the term used to describe the clinical syndrome resulting from the ingestion of food contaminated by certain types of bacteria. Although the affection has occurred more or less frequently, probably for centuries, its etiology and epidemiology, and therefore its control, have not been understood until comparatively recently. Having some knowledge of the etiology and epidemiology of food-poisoning, the lack of control over the mounting incidence of this reportable and preventable condition challenges students of public health and preventive medicine. The records in most departments of public health, particularly in those units enjoying fairly accurate reporting of the notifiable diseases, demonstrate the wide gap that exists between the comparatively poor results obtained with present day practice and those that could be had were the latest approved scientific methods properly applied.

In certain diseases, some of which have been devastating in their effects, as plague, malaria, yellow fever, smallpox, diphtheria, typhoid fever, and cholera, actual control has been approached, and even demonstrated on several occasions, particularly in armed forces; but any statement to the effect that tuberculosis, syphilis, influenza, acute anterior poliomyelitis, measles,

and pertussis, as examples from a large group, are under control, is misleading, to say the least. While the epidemiology is not entirely complete, the etiology is well known in some of the diseases, as tuberculosis and syphilis, and, indeed, we are fairly well informed of methods that may prevent the transmission of the causative factors, as in both tuberculosis and syphilis, but who can deny that even in these diseases new infections arise occasionally from known reservoirs of infection under treatment and so-called supervision?

Obstacles present themselves to resist measures directed at the prevention of the transmission of communicable diseases and of the occurrence of certain non-communicable but preventable diseases; but the justification for public health activities lies in the necessity for overcoming these same obstacles. The possibility of the control of food-poisoning, though not so attractive in some respects, perhaps, as many other problems, is of importance, and offers certain difficulties which merit more attention than that usually given.

It is not the intent of this paper to decry the health official as a disinterested individual of limited intelligence. Frequently, in the past, it has been emphasized that the health officer was usually a man who had one or the other of two backgrounds: he was a failure, or too old to carry on, as a physician or surgeon in the clinical field but the public was willing to have him act as health officer, or, he was a

* Read before the Fourth Annual Meeting of the Western Branch of the American Public Health Association, Pasadena, Calif., May 29-31, 1933.

politically ambitious physician who achieved sufficient prominence to be given the appointment irrespective of his qualifications. Today, however, the field of public health is attracting young men of excellent training and background, in whom there is activity, alertness, and enthusiasm in their expectations of careers in preventive medicine and public health. Too frequently, certain details and problems are lost sight of in the direction of activities in metropolitan organizations or in the varied duties in the limited personnel of rural units. It is the purpose of this paper to point out the need for a better understanding of the problem offered in the control of food-poisoning, to emphasize the obstacles operating against the achievement of actual control, and to outline a program to be followed in approaching the problem.

The etiology and epidemiology of food-poisoning is fairly well understood; indeed, we are better informed on the etiology of this type of illness than we are on many other of the communicable and preventable diseases, as, for example, influenza, acute anterior poliomyelitis, and measles. In methods of control, we do actually know how to prevent food-poisoning, in direct contrast to our comparative helplessness in the face of an outbreak of the diseases mentioned.

It is not possible, in a paper of limited scope, to do more than list and emphasize the major points. Every health official is familiar with the difficulties nearly always encountered in the investigation of food-poisoning, but in directing attention to these points, it is hoped that seemingly lagging interest in the entire problem may be rekindled. Most obstacles can be classified under one of the following major groupings:

- III. Inaccurate understanding of the etiology.
- IV. Incomplete epidemiologic investigation.
- V. Inadequate laboratory studies.
- VI. Incomplete preventive service.
- VII. Restricted dissemination of accurate information.
- VIII. Lack of rational modern legislation.

Most of these obstacles to progress in the control of food-poisoning are met with in the control of all communicable and preventable diseases. With intelligent application of modern methods, all can be overcome. All but the first and last are direct responsibilities of the health official; and even for these exceptions (delayed reporting and lack of rational modern legislation), the health official must accept responsibility for the initiation of procedures necessary for their correction.

It is obvious that the success of any plan of attack directed at the control, not only of food-poisoning but of any communicable or preventable disease, will depend upon the effectiveness with which that plan deals with the obstacles presented. It is apparent, also, that the most important obstacle to be overcome lies in the correction of the lagging interest which affects the public health official as well as the public. The correction of all other difficulties outlined depends, directly or indirectly, on the health official's interest and initiative. The alert health officer will create a consciousness in professional and lay groups, and earlier reporting will be forthcoming; he will educate his organization to etiological understanding and from this background develop adequate epidemiological and laboratory study; he will improve the inspection service rendered by his organization, initiate well-founded and rational legislation, and make every attempt to enforce it with expedition; and, always, he will take advantage of every opportunity to disseminate accurate informa-

- I. Delayed reporting.
- II. Passive interest of health official and public.

tion intelligently and intelligibly. Perhaps the most important step in the control of food-poisoning, therefore, is the education of the health officer.

Food-poisoning is usually considered as of two distinct types: (1) Botulinus poisoning, or botulism, is a comparatively rare affection of high fatality rate, caused by the ingestion of food contaminated with the anaerobe, *Clostridium botulinus*, in which toxic products are formed. (2) Food-poisoning, *per se*, is a rather common affection of low fatality rate, caused by the ingestion of food contaminated with certain types of organisms and their metabolic products, particularly members of the paratyphosus-enteritidis group and, apparently, certain strains of the heavy pigment-producing staphylococci.

In botulinus-poisoning, the clinical manifestations of neurologic dysfunction are probably due to a neurotropic toxin which affects important neurologic centers after an incubation period of from 24 to 48 hours. In food-poisoning, however, the clinical picture is that of a gastrointestinal intoxication, probably due to a gastrointestinal irritant which is the metabolic product of the organism, after a relatively short incubation period of less than 4 hours usually, and less than 12 hours nearly always.

Clostridium botulinus has a widespread distribution in the soil as a spore, and in this form is considered harmless to man. It is killed at temperatures easily attainable in commercial food processing, and the toxic product, formed by the anaerobe in suitable foodstuffs as culture media, is thermolabile, being destroyed by boiling usually within 10 minutes, depending on certain variable factors, as consistence and quantity of the food, size and shape of the container, altitude, et cetera. The foods responsible for botulinus-poisoning are usually of home-canned origin.

The underlying cause for this probably lies in the so-called "cold-pack" method of canning, with inadequate temperatures and holding periods. The danger of commercially canned products as a source of infection in botulism is remote with present-day practice, which includes laboratory studies on each pack.

Members of the paratyphosus-enteritidis or food-poisoning group of organisms are not infrequently traceable to the gastrointestinal tracts of certain carriers, both human and animal, particularly rats and mice. These organisms are killed by comparatively low temperatures, but their metabolic products or poisons may prove to be thermostable at various temperatures for different periods of time. Moreover, certain organisms usually considered innocuous, as, for example, proteus and cloacae groups, when they are permitted to grow in media or foodstuffs of high protein content, may also produce poisonous products which are gastrointestinal irritants to man. It must be realized, also, that even so-called invasive types of organisms, as *B. paratyphosus* (alpha) of human origin, as food contaminants, may cause food-poisoning only, without subsequent infections of more or less severe character.

Epidemiologic studies, while it is desirable to have them carried out by a medically trained personnel, may be made quite satisfactorily by lay inspectors or by public health nurses. The true epidemiologist has an inherent insatiable curiosity, combined with initiative and ability to determine the basic facts. These qualities must be present, at least to some degree, in the individual charged with the responsibility of investigating a report of food-poisoning. The art of question asking, as a means of obtaining accurate and unbiased information, is fundamental in its importance, and, in most instances,

requires development and training. Poorly asked questions often have been responsible for misleading and inaccurate information, in addition to the opportunities lost through the promotion of lack of confidence or antagonism toward the investigator.

The epidemiologist's primary interest lies in the particular food probably responsible for the affection. Careful questioning of a group of the individuals affected will furnish data of value in confirming the diagnosis and eliminating the various unrelated foods. Supplementing the determination of the food probably responsible, the epidemiologist obtains specimens of the food suspected, specimens of stool and urine from the food handlers, and of stool from affected individuals, particularly in those instances in which diarrhea is present. All specimens are to be obtained in sterile containers, without contamination from other sources, and sent to the laboratory, properly labelled, and as soon as possible. The epidemiologist has not completed his work until he has obtained every bit of essential information on the source of the suspected food, and definite data concerning the quality, condition, preparation, holding, storage and serving. The physical environment of the premises in which these procedures were carried out, with special attention to the possibilities of rat, mouse, and other animal infestation, and the methods employed in rodent control, is of import. A history should be obtained from every handler of the food, with specific data concerning the possibilities of any of the enteric fevers, not only recent but throughout his entire life.

Laboratory procedures are not fixed and unchangeable. Constant improvements in technic are being made, and health officials should assure themselves that methods used in their laboratories are kept up to date. The complete laboratory study must include the

application of modern technic in conducting bacteriological, immunological, and biological reactions, and chemical tests as indicated; but these studies should be used as confirmatory evidence and as diagnostic aids only, and should not be substituted for epidemiological investigation. The laboratory worker who relies upon routine procedures of a decade ago is doomed to disappointment. The use of enrichment media, new buffer salts, lower or higher pH levels, closed chambers permitting controlled changes of gas tensions, new immunological reactions, absorption tests, new cultural reactions, animal and human feeding experiments—these and many other refinements of technic are contributions that have made possible adequate laboratory studies in food-poisoning. Most of these are possible in the laboratory that is well equipped but not elaborate in its set-up, and their accomplishment is not beyond the capabilities of the well-trained laboratory worker.

The health official who understands the etiology and epidemiology of food-poisoning, who carries out a rational and reasonably complete investigation, and who has available in his laboratory the latest approved technic, has an efficient agency for the study of food-poisoning outbreaks; and from each study something constructive can be gleaned and in turn practised to prevent recurrences. In the control of food-poisoning, something more is essential.

The regulation and supervision of food establishments as carried out in most organizations is insufficient. Too frequently the food inspection service is concerned with the physical plant alone. Ratproofing, rodent infestation, water-proof floors, smooth, painted walls, refrigeration, ventilation, toilet and lavatory facilities, the outer clothing of the personnel:—these are important, but, in addition, the quality of the food, the preparation, holding, serving, and

handling of food, milk, and water, the cleansing of china and glassware, the polishing of silver, and, probably of greatest importance but so frequently not well supervised, the food handler himself—these are also full of possibilities as sources of infection in food-poisoning. In most cities in which health certificates are issued to food handlers, the medical examination has deteriorated into a venereal disease inspection, and the laboratory study consists of the examination of a smear for the gonococcus and a complement fixation reaction on blood serum, as evidence of gonorrhea and syphilis. The search for the bacillus carrier, not only of *B. typhosus*, but also for *B. paratyphosus*, *B. enteritidis*, and other members of this group, is the valuable examination often overlooked.

These activities are possible, of course, only if adequate legislation supports the health official. Legislation is dependent upon public opinion, and since public opinion is dependent upon education, there is a definite lag between new developments and the passage of legislation permitting the application of newer knowledge.

The great strides made in public health during the past half-century have been accomplished through the application of methods made possible as a result of research in the laboratory and the field. The epidemiologist, the bacteriologist, the immunologist, the physician, the dentist, the sanitary engineer, the public health nurse, the inspector, the veterinarian, the vital statistician, and the legislator—all have played their rôles; but in the years to come, further advances will be slow without health education. Most public health administrators recognize the need for organized programs in health education, but, unfortunately, funds are not available, in most instances, to promote this essential activity. It must be realized, of course, that health edu-

cation, to be effective, must be planned, not in terms of months or years, but of decades. Through the dissemination of accurate information in an intelligible manner, the populace may be educated, and many goals, now seemingly beyond reach, brought nearer. The well-edited bulletin, of attractive though not elaborate or expensive format, regularly issued, and placed in the hands of the interested groups, as physicians, dentists, nurses, educators, teachers, civic leaders, parents and others, is a method deserving attention and study. The statistical leaflet, full of tabulations of morbidity and mortality rates and classified causes of death, with addenda of numbers of inspections made and samples collected, will not meet these requirements; such a periodical is almost never read by those not actually engaged in public health work. The publication should be augmented by other projects, as radio broadcasts, selected newspaper publicity, lectures, and talks to interested civic, service, parent-teacher, professional and lay groups, and by published scientific articles and reports. Every member of the personnel of the department, and particularly the public health nurse, should take advantage of every opportunity in every contact to make friends rather than enemies, to encourage cooperation rather than antagonism, and to teach prevention rather than cure. The opportunities offered in health education are manifold.

SUMMARY AND CONCLUSION

1. The removal of obstacles to the control of food-poisoning justifies public health activities.

2. With an understanding of the etiology and epidemiology of food-poisoning, actual control is not unattainable; but there must be renewed interest on the part of the health official, and, through him, the awakening of professional and lay consciousness.

3. Emphasis is placed on the importance of understanding the etiology and epidemiology, of laboratory procedure and preventive services, of legislation and regulatory supervision of establishments and healthy carriers, and of health education, as measures to be used in a plan for coping with the prob-

lem of the control of food-poisoning.

Food-poisoning, although its cause, effects, and prevention are fairly well understood, continues to be reported. Its control is a not unattainable objective, but it may be reached only through the rigorous application of present-day methods and procedure.

Amendment of Italy's Child Welfare Law

THE Italian law of 1925 establishing a national bureau of maternal and child welfare was amended April, 1933.

The law of 1925 provided for an annual appropriation of 8 million lire. This was soon found to be insufficient; therefore, according to the new law, the amount is to be determined annually.

For the purpose of obtaining greater flexibility the number of members of the council that administers the national bureau was reduced from 38 to 13, and that of the councils who administer the provincial branches of the bureau, called in the law provincial federations, from 21 to 11. Provision was made for the appointment to each provincial council of at least two representatives of maternal and child welfare agencies.

Under the old law each provincial federation had an executive committee of 9 members, selected from the members of the governing council of the federation. The committee attended to routine business, examined the questions to be submitted to the governing council, made suggestions, supervised

the functioning of public and private maternal and child welfare institutions and, in general, the administration of the laws regarding maternal and child welfare. Under the new law the executive committee has been abolished, and for the purpose of greater efficiency the functions of the committee have been transferred to one individual, namely, the president of the governing council of the provincial federation.

Both the old and new laws provide for the establishment in each commune of a committee of citizens to carry out in that locality the functions of the provincial federation. The new law prescribes that the members of this committee must be experienced in maternal and child welfare work, whereas under the old law this was not required.

The old law prohibited the serving of alcoholic beverages, including wine, to children and adolescents in schools and all other educational establishments; the new law specifies an age minimum of 16 years.—*Gazzetta Ufficiale*, Rome, Apr. 26, 1933.

Ten Years of Public Health Administration in Ohio*

ROBERT G. PATERSON, PH.D.

Executive Secretary, Ohio Public Health Association, Columbus, Ohio

IN this interpretation, there is presented the 10-year experience of Ohio in public health administration—1920 to 1929 inclusive. Answers are sought to such questions as: has the number of public health commissioners increased? what was their age? how long have they served? what was their salary? what qualifications did they have? and, what was the relation of the year of their appointment to the year they were licensed and to the date of their graduation?

The significance of the study lies in the fact that Ohio was one of the first states to cease placing reliance upon the township, village, and city subdivisions of government as the units of public health organization. In 1919 the General Assembly passed a law, the Hughes-Griswold Act,¹ which divided the local subdivisions of the state into three possible units for public health administration—the city health district, which embraces all cities in the state²; the general health district, which embraces all townships and villages in each county (referred to here as county districts); and a union of two general health districts or a general health district and a city health district located within such district³ (referred to here as combined districts). This law be-

came effective January 1, 1920. These are the crude figures serving as background material with which the public health organization in Ohio has to deal.

Now what has happened in the administration of this organization in the 10 years which have elapsed from 1920 to 1929?

NUMBER OF HEALTH DISTRICTS

In 1920 there were created 168⁴ health units, 88 of which were general, and 80 city health districts. These replaced the former system in which there were 2,158 independent health districts divided into 80 city, 727 village and 1,351 township units.

Each of these 168 health units had a board of health and each was required to employ a health commissioner, who had to be a licensed physician in the general health district but was not required to possess any qualifications in a city health district.

NUMBER OF HEALTH COMMISSIONERS

Analysis of the number of health commissioners in Ohio by type of service in 1920 and in 1929 is shown in Table III. In 1920 there was a total of 37 full-time and 129 part-time health officials in the three types of districts, while in 1929 the corresponding figures are 63 and 103.

The trend in both city and county units is definitely toward employment of full-time health commissioners and

* Based upon a study made by John A. Ey, Jr., and presented to the Ohio State University in partial fulfillment for the degree of master of arts in the School of Social Administration, 1932.

TABLE I

BASIC DATA FOR OHIO 1920-1930

The Basic Demographic Data for Ohio in the Decade 1920 to 1930

| Year | Population | Area Sq. Miles | Persons Per Sq. Mile | Number of | | | Per Cent | |
|------|------------|-------------------|----------------------------|---------------|--------|----------|----------|-------|
| | | | | Coun- ties | Cities | Villages | Urban | Rural |
| 1920 | 5,759,394 | 40,740 | 141.4 | 88 | 94 | 725 | 63.8 | 36.2 |
| 1930 | 6,646,697 | 40,740 | 163.1 | 88 | 110 | 752 | 67.7 | 32.2 |

a combined unit as the basic unit in administrative service.⁵

AGE OF HEALTH COMMISSIONERS⁶

The average age at appointment in 1920 was 44.3 years for full-time and 51.5 for part-time county districts; 48.0 years for full-time and 50.6 for part-time city districts; 43.2 years for full-time and 59.0 for part-time combined districts, while in 1929 the corresponding figures are 47.0 and 46.6; 42.5 and 30.6; and 39.0 for full-time combined districts.

Health commissioners appointed in the earlier years 1920 and 1921 were in the higher age groups while in the ensuing years, especially since 1926, the tendency has been to appoint younger officials. This is more true in the cities and combined districts than in the counties.

LENGTH OF TENURE OF HEALTH COMMISSIONERS

The data show that more officials served the entire 10-year period 1920-1929, than for any other number of years in the one office—20.2 per cent in the counties and 18.7 per cent in the cities. The average length of tenure for the three types of districts of the full-time officials is 4.9 years in the counties; 4.3 years in the cities and

4.0 years in the combined districts; of the part-time officials 4.9 in the counties; 5.1 in the cities. There were only 2 part-time officials in the combined districts so their experience cannot be compared with the two other types in this classification.

SALARY TRENDS

The group with the most officials within its limits received \$4,000 to \$4,500. The full-time officials in the counties and cities predominate in this class. Salaries of officials in the cities, both full-time and part-time, are rather low, 84.9 per cent under \$2,500. In the counties 82.3 per cent received less than \$3,500. In the three types of districts a total of 96.6 per cent received less than \$3,500. In only one group,

TABLE II

BASIC VITAL STATISTICS DATA FOR OHIO 1920-1930

| Year | No. Deaths All Causes | Death Rate per 1000 | No. Births | Birth Rate per 1000 |
|------|--------------------------|------------------------|------------|------------------------|
| 1920 | 73,846 | 12.7 | 124,303 | 21.4 |
| 1930 | 75,500 | 11.4 | 117,611 | 17.6 |

TABLE III
NUMBER OF HEALTH COMMISSIONERS 1920 AND 1929

| Year | County | | | City | | | Combined | | |
|------|--------|-------|----|-------|-------|----|----------|-------|----|
| | F. T. | P. T. | T. | F. T. | P. T. | T. | F. T. | P. T. | T. |
| 1920 | 28 | 49 | 77 | 4 | 79 | 83 | 5 | 1 | 6 |
| 1929 | 26 | 45 | 71 | 18 | 57 | 75 | 19 | 1 | 20 |

(F.T.—Full-time; P.T.—Part-time)

those serving full-time in the counties, does the average salary for each year show a steady increase.

QUALIFICATIONS

The fact that by law all county health commissioners must be licensed physicians sets up uniform educational qualifications. Of the total of 83 full- and part-time officials in 1920 in cities, 61.4 per cent were licensed physicians. In 1923 this figure rose to 67.9 and in 1925 to 75.6. Physicians predominate among the health commissioners in cities since less than one-third were not licensed physicians. This has been found to be the case in other states as well as Ohio.⁷

Additional professional qualifications such as special university training in public health is so seldom encountered as to be negligible.

YEAR OF APPOINTMENT

The figures showing the relation of the year the officials were appointed to the year they were licensed as physicians and to the date of graduation from medical college reflect the tendency toward appointment of young commissioners in the cities. This is true especially since 1926. In the counties, however, since 1925 the trend has been to appoint officials in the older age groups.

CONCLUSIONS

The study covering the 10-year period 1920–1929 shows a definitely increased trend toward the employment of full-time health commissioners; there is a tendency toward the establishment of combined units of organization including the general and city health districts in a single administrative unit; the age of officials at appointment is in the direction of the younger age groups, 30 to 50; the salary level is low with the trend downward rather than upward; and about the only educational and professional qualifications required are those which are embraced in the general term "licensed physician."

Before public health administration in Ohio can be said to have reached a professional rather than an apprentice status it is evident that several fundamental principles must be established. There must be assured a sufficient tenure of office—not less than 5 years and preferably 7 years; a salary scale graded commensurately with the type and composition of the unit organization; a recognition that a public health administrator should have special university training similar to that required of our school administrators; a clearly defined set of qualifications beyond the blanket term "licensed physician" needs to be established to enable the tax payers to form judgments on this

point; and increased opportunities for special training should be afforded prospective public health administrators in our universities throughout the state.

2. A city in Ohio in contradistinction to the definition of the U. S. Bureau of the Census, Department of Commerce, is defined in the State Constitution, Article XVIII, Sec. 1: "Municipal corporations are hereby classified into cities and villages. All such corporations having a population of 5,000 or over shall be cities; all others shall be villages. The method of transition from one class to the other shall be regulated by law (adopted Sept. 3, 1912).

The regulation provided by law is that "municipal corporations, which, at the last federal census, had a population of 5,000 or more, shall be cities. All

other municipal corporations shall be villages. Cities which, at any future census, have a population of less than 5,000 shall become villages. Villages which, at any future federal census, have a population of 5,000 or more, shall become cities" (96 v. 20, p. 1) (Section 3497, Page and Adams Annotated Ohio General Code, Vol. 2, p. 3).

3. Subsequent amendment provided for a union of a city health district and a general health district or *vice versa*. (Laws of Ohio, 1931, Vol. 114, pp. 114-115.)

4. One general health district covering a small rural county without a city in it has never been organized permanently under the present law.

Milk and Growth

1. The influence of the addition of milk to the diet of school children is reflected in a definite increase in the rate of growth both in height and weight.

2. There is no obvious or constant difference in this respect between boys and girls, and there is little evidence of a definite relation between the age of the children and the amount of improvement. The results do not support the belief that the younger derived more benefit than the older children. As manifested merely by growth in

weight and height the increase found in younger children through the addition of milk to the usual diet is certainly not greater than, and is probably not even as great as, that found in older children.

3. In so far as the conditions of this investigation are concerned, the effects of raw and pasteurized milk on growth in weight and height are, so far as we can judge, equal.—Leighton and McKinlay (1930), Dept. of Health for Scotland. Milk Consumption and Growth of School Children. *Report of an Investigation in Lanarkshire Schools*.

Industrial Dermatitis in the United States*

LOUIS SCHWARTZ, M.D.

Senior Surgeon, U. S. Public Health Service, New York, N. Y.

IN some countries, especially England and Germany, more attention has been paid to industrial dermatitis than in the United States. Since the promulgation of Workmen's Compensation Laws, the problem of industrial dermatitis has become of greater importance than ever in this country. Industrial dermatitis or occupational eczema contributes about 50 per cent of all claims for compensation due to conditions classified as industrial diseases. Even this does not represent the real incidence of occupational eczema because the majority of cases of industrial dermatitis do not incapacitate the worker, and only those workers put in claims for compensation who must stay away from work for one week or longer.

In our inspection of plants, we noted workers at their jobs affected with varying degrees of occupational dermatitis. Most of these cases were not reported, either because they were not serious in nature, or because the workers feared that a claim for compensation might militate against their retaining their positions. There were a few severe cases of dermatitis in men who were working because the compensation they might receive was less than they could earn.

We found some workers not reporting their condition because other workers

had told them that many new employees were affected in the same way, and that if they kept on with the work, they would become hardened and no longer be troubled.

FREQUENCY OF OCCURRENCE

Skin diseases are associated with many occupations, the rubber industry causing rubber itch, tanning of leather chrome sores, oil refineries oil acne, dyeing establishments dye dermatitis, etc.

The amount of industrial dermatoses reported by the hospitals is very small. In one hospital in New York where there are over 20,000 new skin cases treated a year, there were only 53 cases per year of industrial dermatitis; in another having 5,000 new skin cases per year, only 5 cases per year of industrial dermatitis. In a private industrial clinic servicing various manufacturing establishments in Greater New York, out of 33,000 cases of all kinds treated over a period of one year, there were 103 cases of dermatitis.

According to statistics gathered from the States of New York, Missouri, Connecticut, Massachusetts, Wisconsin and Ohio, of 19,428 occupational diseases reported during the period covered by the records, 9,621 were occupational dermatitis, or about 50 per cent. In these states there was an average of 2,944 cases of occupational dermatitis per year—an annual rate of 48 per 100,000 of the industrial population.

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

These include only the more severe cases of dermatitis, and it is safe to say that if the minor cases which are not reported, or which are not disabled for a period of one week or more, were counted, it would be shown that there are many times this number of cases actually occurring per year in the United States.

CASES FOUND IN THE PRESENT STUDY

In the present study the industries examined were selected at random and not because of any undue prevalence of dermatitis. They included dyeing establishments, rubber works, oil refineries, candy makers, linseed oil works, and chemical manufacturing. Out of 18,567 workers examined, there were 285 occupational skin diseases found, a rate of prevalence of $1\frac{1}{2}$ per cent.

CAUSATIVE AGENTS OF INDUSTRIAL DERMATITIS

The chief causes of industrial dermatitis differ in the various localities according to the prevailing types of industry present.

In New York State of 232 industrial dermatitis claims about 26 per cent were due to general irritants, such as acids, alkalies, chrome and turpentine, 13 per cent were due to plant and vegetable poisoning and 10 per cent were to dyes. Gasoline, benzine, oil and naphtha account for about 10 per cent.

In Missouri out of 1,020 cases, 69 per cent were due to lime and cement, 6 per cent to lye, 15 per cent to poison ivy, $1\frac{1}{2}$ per cent to petroleum and 9 per cent to caustics and sulphuric acid.

In Wisconsin in the past ten years, of 1,909 cases of dermatitis, 17 per cent were due to toxic vapors, 42 per cent to toxic fluids, 20 per cent to irritating dusts and 15 per cent to poisonous dusts.

In Ohio, irritating dusts associated with the rubber industry have led the

list of causes of industrial dermatitis. Oils and cutting compounds, including lubricants, have been a close second, and at the present time, according to Dr. Hayhurst, undoubtedly lead the procession of skin irritants.

From these statistics, it can be stated that the majority of occupational skin diseases in these states are caused by acids, alkalies, caustics, oils, greases and solvents.

Plant poisoning by ivy, oak, sumac, primrose and wood dusts occurring among florists, gardeners, and carpenters, constitute a considerable percentage of cases of occupational dermatitis. In New York State out of 449 cases, 14 per cent, and in Ohio, out of 4,600 cases, over a 5-year period, 2 per cent were due to this cause.

COMPENSATION FOR INDUSTRIAL DERMATITIS

Only 11 of our states compensate for industrial skin diseases. The compensation laws in these states are not all the same. Some compensate for any occupational disease arising out of and in the course of employment; others specifically name the causative agent. Dermatitis is not specifically mentioned in some while in others the causative agents for which occupational dermatitis is compensated are named.

What is reportable or compensable in one state may not be so in another. This makes it very difficult to compile reliable statistics from the records.

CLASSIFICATION OF CAUSES OF OCCUPATIONAL DERMATITIS

To give a list of substances causing industrial dermatitis would be to give a list of almost every known chemical or substance, because idiosyncrasy or hypersensitivity or allergy can be developed towards almost any substance. The causative agents can be classified in various ways. One manner is as follows:

1. Physical Agents—such as heat and cold, radiation, etc.

2. General Irritants—such as acids, alkalies and caustics, etc.

3. Specific Irritants—These do not affect everybody but cause skin rashes in a considerable percentage of people. Such are paraphenylenediamine, hexamethylenetetramine, benzene, and certain oils and plants.

4. Fat Solvents—These act by dissolving the fat and oil from the skin and making it more sensitive to irritation.

5. Dehydrators — Crystalline substances which act by absorbing the moisture from the skin, such as salt and sugar.

6. Biologic Agents—Bacteria and pathogenic fungi.

Then there is a group of substances which affect only the skins of hypersensitive people. If these are met with at the place of employment, then the dermatitis is an industrial dermatitis due, partially to the substance and, partially, to the hypersensitivity of the individual.

There is still another group of people who, at first, are not sensitive to the materials with which they work, but after exposure to them for varying lengths of time, become sensitized or allergic and develop a dermatitis. These allergic forms of occupational eczema are related to hay fever, asthma and serum sickness.

CLINICAL FORMS OF OCCUPATIONAL DERMATITIS

Occupational dermatitis is, in its acute form, a dermatitis venenata, and does not have any characteristic appearance except when caused by a few substances such as arsenic and poison ivy.

Fat solvents cause the skin to become dry and cracked, and dehydrators give a parchment-like, scaly appearance. Aside from the few general characteristic appearances caused by a few skin irritants, the appearance of the skin gives no clue to the irritant causing the condition.

Occupational dermatitis in its acute

stage is characterized by erythema, edema, papules and vesiculation of the exposed parts. Other parts of the body may also be affected, especially when the clothes are penetrated by the offending material. Later on crusting and desquamation may occur. Complications such as pus formation and parasitic infections may entirely change the picture of the original disease.

The first attack of occupational dermatitis may disappear while the person is working and it may never appear again. It may disappear after the person stops working and not appear again upon resuming work, or it may disappear upon stopping work and reappear when resuming the work, or it may become chronic with acute exacerbations.

It is characteristic of a typical occupational dermatitis that it appears when the person is exposed to the offending substance, disappears after the exposure has ceased and reappears when the person is again exposed. This is a classical picture and is not always met, because other conditions complicate the matter.

There are some people who, when they first begin work, develop a mild dermatitis which, after a while, disappears, leaving them immune. There is another class in whom the dermatitis develops in so severe a form that it necessitates staying away from work, and when they return to work the condition reappears. Such people are likely to discontinue that occupation of their own accord. There is still another class who develop an immunity while working but this is short lived, and if they discontinue working for a week or two, then come back to work, they again contract the dermatitis and again may develop an immunity. In other words, continuous exposure among such people develops an immunity which lasts a short time.

Some workers have alternating re-

missions and exacerbations of dermatitis while at work. These cases are difficult to explain. It may be possible that the conditions under which they work are not constant although they appear to be. The dermatitis itself may exhibit a periodicity due to variations in the resistance of the patient or to variations in his sensitivity.

There is still another group of cases described by Rudolph L. Mayer, in which the primary dermatitis is followed by frequent relapses and, finally, a chronic condition persists even after elimination of the offending substances; that is after giving up the employment. Mayer explains that in these cases there gradually develops a nonspecific polyvalent sensitivity of the skin to many things that are encountered in the course of daily life. Secondary infections with pus organisms and molds may also take place in these cases, and the resultant sensitivity may complicate the disease. It is very difficult in such cases to prove that occupation was the original cause of the condition.

DIAGNOSIS OF INDUSTRIAL DERMATITIS

In making examinations of workers, many skin conditions such as psoriasis, lichen planus, impetigo, scabies, etc., were found which had no relation to the occupation. In making a diagnosis of industrial dermatitis, it must be determined whether or not the man is exposed to a general irritant, and if he is, whether the eruption developed before or after beginning the occupation. If there is no exposure to a general irritant, it must be determined whether there is a sensitivity to any of the materials with which the person comes in contact in the course of his employment. This can be done by means of patch tests, applied as follows:

Eight thicknesses of gauze $\frac{1}{2}$ inch square are saturated with the material suspected of causing the dermatitis, and placed on a clear portion of the

skin. It is best to select, if possible, a clear portion of skin immediately adjacent to the eruption on the theory that the portion of the skin nearest to the eruption is most sensitive to the chemical. The gauze is covered by a piece of dental rubber about 1 inch square so as to keep in the moisture. This is covered by a piece of cotton flannel about $1\frac{1}{2}$ inches square, in order to keep in the heat, and covered with a piece of adhesive plaster 2 inches square. The patches may be removed at the end of 24 hours and the skin underneath inspected. If the skin is sensitive to the material, there will be a reaction varying from an erythema designated as +; to an erythema with edema designated as ++; erythema, edema and vesiculation, designated as +++; to an erythema, edema and ulceration designated as ++++.

In cases where materials are used which are innocuous to a normal person, the patch may sometimes be left on for as long as five or six days in order to obtain the reaction. Care must be exercised in doing patch tests with general irritants. If hypersensitivity to dilute solutions of these materials is suspected, then such dilutions of them are to be used as will not ordinarily affect the normal skin. For instance, a 1 per cent solution of potassium bichromate has been found not to affect the non-sensitive skin but does produce a reaction in people sensitive to chromium. In the case of turpentine sensitivity, 1 part of turpentine to 9 parts of olive oil may be used. I have found cases in the candy industry so sensitive to the oil of cinnamon that a solution of 1 drop of oil in 49 drops of olive oil produces a marked reaction after 24 hours.

In doing patch tests, it is best to have controls, using an individual who is doing the same work as the patient but who shows no skin eruption. A blank control patch or one with some other

substance can also be used. Sometimes there is no reaction found under the patch when taken off, but a day or two later a reaction develops at the site of the patch. These are called delayed reactions and also indicate a hypersensitivity.

Patch tests, if properly done, are reliable in showing either acquired or natural hypersensitivity. If they do not give positive results, intradermal tests similar to those done for asthma may be tried, but these are of less diagnostic value.

EPIDERMOPHYTOSIS AS AN OCCUPATIONAL DISEASE

Fungus infections and epidermophytids offer a serious problem in the diagnosis of industrial dermatitis. It is often very difficult to say whether the condition is due to a man's occupation or not.

In our inspection of the workers in the various plants, we often came across cases of fungus infection of the hands and of apparent allergic reactions called epidermophytids or trichophytids on other parts of the body due to absorption of substances from the localized fungus infection. These were, in many instances, wrongly diagnosed as occupational dermatitis. There are, however, certain occupations which predispose to fungus infections because, during the course of employment, the person is exposed to pathogenic fungi or because the skin becomes moist, hot and macerated, and forms a favorable site for the growth of fungi. Barbers and bathhouse attendants are examples in which there is a special exposure to the action of fungi, and among them fungus infections of the hands, feet and nails are often seen. Among stokers, firemen and men who work in rubber vulcanizing pits, there develops, on account of heat and moisture, a soggy condition of the skin in the interdigital spaces, and this favors the development of fungi. We

have also found an unusual prevalence of tinea of the hands and feet among workers with raw wool.

CANCER AND OTHER GROWTHS IN INDUSTRY

Certain industries predispose to the development of carcinoma. Carcinoma of the bladder occurs with unusual frequency among workers in synthetic dyes. Arsenic has also been blamed as a cause of cancer. We are all familiar with the carcinomatous degeneration taking place in X-ray and radium burns among physicians and technicians handling X-rays and radium. Cancer of the scrotum among chimney sweeps in England has been known for many years, and a similar condition has been discovered among arsenic smelters.

In workers in some of the oil refineries in this country, we have noted carcinoma of the cheek and of the lip, and among paraffin pressmen, of the hands and of the scrotum. We have also noted an unusual prevalence of small, flat, pigmented papillomata on the dorsum of the hands, the forearms and legs of workers in oil refineries and among machinists and mechanics who handle oils and greases. More than 10 per cent of such workers were found to have these growths.

Among mule spinners in England there is reported an unusual prevalence of carcinoma, but in a large woolen mill in this country, we found no cases of carcinoma. It may be that the oil used in softening the wool in this country is different from that used in Europe. The factory in which our examinations were made used vegetable oil.

PREVENTION OF INDUSTRIAL DERMATOSES

The ideal prevention would be so to safeguard the industries which are dangerous that the injurious chemical could not come in contact with the skin of the worker. This is impossible in a

great many cases. Protection of the worker against irritating substances such as acids, alkalies, caustics, etc., by the wearing of suitable rubber gloves and clothes will often keep down the number of cases of industrial dermatoses.

In factories where such irritating substances as the irritant dyes, paraphenyldiamine, etc., are used, or the rubber industry where certain irritants in the form of accelerators and anti-oxidants are used, patch tests may be done on applicants for employment to determine their susceptibility to the materials which they will be called upon to handle, and those found to be hypersensitive should be rejected. Those workers who become sensitized after a long period of occupation should be shifted to other departments.

In factories where the skin hazard is great, personal hygiene must be emphasized. Workers must take baths and change clothes before leaving the plant, and for this purpose adequate toilet and washing facilities should be provided. Supplying clean towels daily to workers in oils and greases with instructions to wipe the hands and arms frequently has, according to Dr. Hayhurst, kept down the number of cases of dermatitis. Chemists and engineers should constantly strive to substitute harmless substances for the irritants which are now used. The installation of proper ventilation, exhaust hoods, totally enclosed dust-proof and gas-proof units

will, by allaying dust and fumes, play a large part in preventing the occurrence of industrial dermatoses. Protective ointments smeared over the exposed parts have, in some instances, been advocated.

TREATMENT OF INDUSTRIAL DERMATOSES

A person who is sensitive to the materials with which he works should seek some other occupation. Industrial dermatoses if uncomplicated will disappear when the person is away from the substance which has irritated his skin so that a cessation of work will usually cure the condition. If complications in such forms as suppuration or parasitic infection have set in, they must be treated and they may not be easily amenable to treatment. If a man must go back to his work after he is cured, he should be told to protect the parts by wearing long sleeves or gloves or by rubbing in protective ointment, as advocated by Dr. J. S. Millard of the Goodyear Rubber Company.

Desensitization by injecting minute quantities of the offending material underneath the skin has been tried but with no great success.

New synthetic chemical compounds are constantly being discovered and used in new industrial processes and many of these compounds are skin irritants. This constantly increases the industrial skin hazards and challenges the ingenuity of the sanitarian in devising preventive measures and cures.

LETTER TO THE EDITOR

TO THE EDITOR:

In *Community Health Organization*, 1932 edition, by Professor Ira V. Hiscock, there are certain figures and statements on present standards of laboratory work per 100,000 population which have recently been critically examined by the Council of the New York State Association of Public Health Laboratories. As a member of this Council I have been interested in comparing the standards offered with the actual experience in public health laboratories of New York State. While I fully endorse the introductory paragraph of the chapter on Laboratory Service, it is impossible to subscribe to what he offers as present standards of laboratory work.

The implications in this chapter are that a community can provide adequate laboratory service for 100,000 people by facilities to do 6,000 public health examinations a year. With the coöperation of others on the Council a table has been prepared, showing the experience in New York State for the last 3 years for which figures are available. From the recorded experience in this state it is quite clear that all of Professor Hiscock's figures are much too low, viewed either from the standpoint of representative urban or rural communities. Six thousand public health examinations a year per 100,000 population are only a fraction of the necessary work. It is unfortunate to have the erroneous impression go forth that a community of 100,000 people can on such a basis establish or maintain adequate laboratory service.

The accompanying table has been compiled so that the discrepancies between Professor Hiscock's figures and those recording the experience in New

York State are made to appear as small as possible. Many essential public health examinations such as those in the diagnosis of poliomyelitis, amebic dysentery, septic sore throat, and laboratory examinations which are for clinical diagnosis and not, strictly speaking, a part of public health work, are not included in these figures because statistically they are grouped under "Miscellaneous." Of course, such a distinction is open to question.

Broadly considered, the public health work in any community is directly dependent upon and proportional to the standards of medical practice in that district, and early differential diagnosis of disease is an essential basis for safeguarding the public health even if considered only from the point of view of the control of epidemics and the spread of communicable disease. I have made no attempt to include any figures for laboratories not on the list of those approved in New York State, so that the statistics from these districts are conservative in that they probably do not represent the actual total.

The method of handling the figures has in another respect made the discrepancy between those in this book and the New York State figures less marked. Those in the table are for a 3-year average. During the period covered the increase has been about 27 per cent. If only the figures for 1931 were compared with Professor Hiscock's, the inadequacy of 6,000 examinations a year per 100,000 population would appear even greater.

Making all these allowances in favor of Professor Hiscock's estimate, it still seems clear that 6,000 examinations a year per 100,000 population are less than one-third of the number that

TABLE

| | Public Health Exams. per 100,000 pop. | Wasser- mann Exams. per 1,000 pop. | G. C. Smears per 1,000 pop. | Diphtheria cultures per resident deaths | Tuber- culosis Exams. per resident deaths | Widals per resident deaths |

(1) "Public Health Examinations": Figures used do not include such examination as Throat Cultures for predominating organisms, spinal fluids, stools for ova and parasites, urines, etc., which might have been public health work but which are statistically grouped under "Miscellaneous" in the Annual Report of the Division of Laboratories & Research. Neither have we included examinations done by laboratories approved only for milk and water tests, such as dairy company laboratories.

(2) Sources of information:

(a) Actual figures of tests done in above laboratories taken from annual reports submitted to the Division of Laboratories & Research, New York State Dept. of Health, using an average of 1929, 1930, and 1931 figures.

(b) Population figures taken from U. S. Census, 1930.

(c) Figures for resident deaths secured from Division of Vital Statistics, New York State Dept. of Health. An average of 1929, 1930, and 1931 rates was used.

(d) Resident deaths for year 1930 used.

(e) Examinations done at Utica State Hospital not included.

(f) Examinations done by Division of Laboratories & Research (State Lab.) not included.

(g) Examinations done at Clin. Lab. Medical Adviser's Office, Cornell Univ., not included.

Note: Total public health examinations done in above urban and rural laboratories increased 26.9 per cent from 1929 to 1931. The 3-year average used in above calculations therefore gives in most cases a lower figure than that which existed in 1931 or 1932.

The laboratories of Tompkins, Otsego, and Cattaraugus Counties were selected as most representative of the purely rural districts where only the county laboratory operated and where there are no large cities.

present standards and an adequate health program demand. In this connection a recent survey by the New York State Association of Public Health Laboratories in New York State showed that in many localities the physicians fail to use the laboratory facilities as much as they should. Hence, the New York State figures are smaller than a really adequate public health program requires.

A second point requiring comment is the implication in the chapter on public health laboratory service that a trained pathologist as director of the public health laboratory is unnecessary. He states that the chief of the laboratory service should be a bacteriologist, and the inference, I take it, is that the director need not be a graduate in medicine. Again the experience in New York State, in the

opinion of many who have observed the workings of public health laboratories, is at variance with this point of view. One of the most useful functions of a director of a public health laboratory is to coöperate with practising physicians in a consultant capacity and to disseminate information on all types of laboratory procedures. These contacts and the correlation of the clinical aspects of public health work and laboratory diagnosis can be achieved far more successfully if the director of the laboratory is a graduate in medicine who has been trained in pathology. The experience in New York State appears to have demonstrated that a population of 100,000 people should have a public health laboratory under the direction of one of great experience and wider point of view than a bacteriologist without training in medicine.

From the foregoing it obviously follows that Professor Hiscock's budget allowance is also inadequate. Accurate

figures of the experience, from the budget point of view, of the laboratories in this state are not readily available, but the inadequacy of the budget given by Professor Hiscock for a laboratory in a community of 100,000 is only a little less than that of his figures for the number of examinations.

Note: If the figures for "examinations" in Hiscock's book refer to specimens submitted for examination and not to the laboratory tests performed, the validity of the criticism offered in this communication is unaffected. The New York State figures given in the accompanying table are for "examinations." Only in the case of the complement-fixation test for syphilis is there much difference between the figures for "examinations" and those for "specimens" and here the percentage difference is less than 100. In all the other tests included in the table the difference between "examinations" and "specimens" is trivial.

Cooperstown, N. Y.

TYPHOID CASES AND DEATHS IN NEW YORK STATE

A CORRECTION

IN a recent advertisement prepared by Wallace & Tiernan Co., Inc., and published in this *Journal*, there appeared a reproduction of an Associated Press item which said: "Since 1928 there have been 10,000 fewer deaths and 100,000 fewer cases of typhoid fever than if the 1928 level of the disease had prevailed."

Obviously the Associated Press

report was at variance with the facts, as there were only 209 deaths from typhoid fever in New York State in 1928.

We are informed that the statement should have read 1906 and are asked by the advertisers to offer this explanation and to clear the New York State Department of Health of any responsibility for the erroneous statement.

ENCEPHALITIS IN ST. LOUIS

THE epidemic of encephalitis in St. Louis, Mo., is the major medical event of the year so far. While attention was called to some cases about the third week in August, there is evidence that they began late in July. At the present writing, 475 cases, with 71 deaths, have occurred; but of course these figures are good only for the time of writing. The mortality has been about 14 per cent.

There have been cases of encephalitis lethargica in St. Louis in 1919, 1924, and 1932, but the present outbreak is by far the most serious which has occurred. It bears little resemblance to the classic disease described by Economo in 1916 and 1917 in Vienna, but is much more like that on the Inland Sea of Japan in 1924,¹ which was similar to that seen in Australia in 1917-1918, and called there the "Mysterious X-disease." The death rate in Australia reached 70 per cent. The present epidemic differs from that, in which 50 per cent were under 5 years of age, in that the great majority of cases are over 15 years—only 19 per cent being under this age—and the case fatality is greater in the higher age groups—35 years and above. Japan has experienced 13 outbreaks, one of which in 1873, though limited in extent, showed a mortality of between 80 and 90 per cent. The largest epidemic in Japan was in 1924, which came on suddenly, showing a large number of cases in widely separated areas almost at the same time. Some 7,000 cases occurred, with a death rate of 60 per cent, 66 per cent of which were over 40 years of age, and 34 per cent under that age. Two smaller epidemics have occurred in Japan since that time, in 1925 and 1929, the last with a death rate of 65 per cent.

The epidemic in St. Louis corresponds more closely to the Japanese type as described than any other of which we know, yet there are many cases which do

not correspond with this type, and it is not too much to say that not only the profession in St. Louis, but the officers sent there from Washington by our Public Health Service are puzzled over the situation, and are not prepared to make dogmatic statements. The epidemics in Japan showed a tendency to reach their peak about the last week in August. The great epidemic of 1924 occurred in a summer which was unusually dry and hot, which is true of St. Louis also, the summer having been the driest since 1837.

St. Louis offers a situation which is unique in some respects. The city is credited with 1,200,000 inhabitants. The city proper has not enlarged its boundaries since 1876. Whenever expansion became necessary on account of the increase in population, municipalities have been founded in suburban areas around it. There are upwards of 20 such municipalities, each having its own separate government, yet one does not know when he is in a suburb and when in the City of St. Louis. These groups, which are politically separate entities, correspond to what would be generally called outlying wards. The drainage problem has been acute. The river Des Peres has been used as a common sewer, and whenever the wind is in the right direction the stench is observed in the city. All of these outlying municipalities drain into some such stream, the majority into the river mentioned, which is at best little more than a creek.

The mosquito situation this year is extreme. There have been four dry years in succession, and the present summer has been excessively dry, only one really heavy rain having occurred since June. The result is that this common sewer is unusually foul. According to the testimony of an expert from the Public Health Service, an ordinary tumbler full will contain from 5,000 to 8,000 mosquito larvae. The Health Officer states that anywhere along this stream where there is a quiet place, one may dip up a mixture which is three-fourths larvae and one-fourth water—as he expressed it, “a living soup of larvae.” Of course attempts have been made to connect the sewage situation with the outbreak, so far without any success or apparent good reason; but other lines of research have been equally abortive. However, as a matter of precaution, all patients in hospitals are screened.

So far, approximately two-thirds of the cases have occurred in what is called St. Louis County, embracing the various municipalities referred to, and one-third in the City of St. Louis. In the business section where comparatively few people reside, there have been few or no cases. The section of the city occupied by thrifty people of German descent has been practically free, as has also University City, which corresponds to this in thrift and cleanliness. There have been only 14 cases among the Negroes who form 12 per cent of the population, although the housing in the section occupied by them is perhaps the poorest anywhere.

In only four instances is there positive evidence of 2 cases having occurred in the same house. In one, a nurse and a child were stricken simultaneously, pointing to a common cause, rather than to contact one from another. The experts studying the situation all admit that there are many more cases than have been reported, which one would expect. There have also been many cases not diagnosed as encephalitis, which when looking backward would probably be classed as mild or abortive cases of the disease.

One striking feature of the outbreak is that the patients who do not die get well quickly, in some cases, as a neurologist connected with one of the hospitals in the city says, “miraculously so.” It is, of course, too early to speak of subsequent damage to the nervous system. Some effects may appear, as they have in

other epidemics, after several months, but at present, complete and even rapid recovery seems to be the rule.

Post-mortems have been done on all patients who have died. The lesions found so far are of the same nature, but at a higher level and more diffused than usually found in lethargic encephalitis. The cortex is involved and there is no tendency toward a localization in the central nervous system such as the basal ganglia and the brain stem. Many cases show a marked inflammation of the kidney with rather diffuse hemorrhages.

The incubation period seems to be 5 to 12 days, and the onset fairly sudden—in many cases extremely so.

The U. S. Public Health Service has been invited into the city. Already seven officers have been there and four more have been ordered to report. The Federal Treasury Department has granted \$25,000 for a study of the disease. Senior Surgeon J. P. Leake has been in charge of the epidemiological study. Dr. George W. McCoy, Director of the National Institute of Health, has been there for some days in a consulting capacity. Dr. L. L. Williams, who is in the plague unit of the Public Health Service, and has been trained as a mosquito man, has made a survey of the territory and, more recently, Dr. Cornelius B. Phillip, an entomologist connected with the Rocky Mountain Spotted Fever Laboratory in Hamilton, Mont., has arrived. Those recently ordered include laboratory experts, epidemiologists and special research men. The Health Department of the city is under the competent management of Dr. J. F. Bredeck, with Dr. P. J. Zentay as Assistant Health Commissioner.

Needless to say, the school situation has attracted much attention. The schools in St. Louis have opened on schedule September 5, with some 95,000 enrollments. The various colleges throughout the state will also open as usual, though there is some alarm being shown by those who have enrolled, and some are cancelling their reservations.

No cases have been reported from central Missouri, but some 45 have occurred in the neighborhood of Kansas City. A house-to-house canvass will be made, and it is to be hoped that the opportunities for study will clarify some of the problems connected with encephalitis in general. It remains to be shown whether the various epidemics considered, as well as the one at present in St. Louis, are due to distinct etiological entities, or can all be referred to a single causative agent, at present unknown, as is the mode of transmission, though personal contact seems now to be the most important factor.

NOTE: At the present time, September 21, the epidemic shows signs of decline. Total cases number 910, deaths 160—in the City, 428 cases and 83 deaths; in the County, 482 cases and 77 deaths.

VITAMIN D MILK AND THE HEALTH OFFICER

THE progress of science often creates new administrative problems for public health officials. The development and increasing popularity of "Vitamin D Milk" is an example, for the widespread use of this desirable antirachitic has raised important questions as to its most effective control by health officers and food and drug officials.

Although vitamin D milks have been on the market for only about two years,

they are now distributed in more than 100 cities in 20 states.¹ At first such biologically activated milks were confined to certified milk and were produced under rigidly controlled scientific conditions by those who conducted the research work and developed the products. Later, other certified and Grade A pasteurized milks were properly included, but now a few dealers are offering lower grades of milks with increased vitamin D potency.

Since the primary function of these biologically activated milks is to supply vitamin D in sufficient quantities to prevent and cure rickets in infants and young children, it is obvious that only milks of known high sanitary quality and low bacterial content should be used for this purpose. The utilization of possibly inferior quality milks, with relatively high allowable bacteria contents, as carriers of vitamin D is, in fact, usually done for mercenary and competitive purposes, and not as a contribution to public health. For these reasons, such milks should not be tolerated.

Three methods for the production or preparation of vitamin D milk are now in operation. The first and most widely employed is a natural method, in which irradiated yeast is incorporated in adequate amounts in the feed of cattle. By the proper use of this system, fluid milk is obtained with an entirely satisfactory vitamin D potency, sufficient to cure rickets when from 20 to 24 ounces are consumed daily. This method is best carried out on large farms having proper technical facilities, since intelligent and competent supervision is required.

The second method is by the carefully controlled direct irradiation of the fluid milk by carbon arc lights of proper strength. Here again, careful supervision by experts is necessary. This process may be compared to pasteurization as a treatment of milk, a desirable process which is a necessary factor in disease prevention. According to Hess,² irradiation of fluid milk provides the most desirable anti-rachitic for the community prevention of rickets, a malady which is now much too prevalent in this country. This method is in operation in Detroit, but has not yet been adopted in other cities, although a well known brand of dried milk made from irradiated fluid milk has been on the national market for several years.

The third method is by the addition of a concentrate of cod liver oil to milk. The concentrate is supplied to milk dealers who are instructed as to the proper ways of adding it, and a considerable number of dairymen have been licensed to use this system. As pointed out in the report of the Committee on Milk and Dairy Products,³ such a vitamin D milk is a modified milk and should be labelled as such. Some authorities have characterized this process as an adulteration of milk. As in the cases of the other two methods, intelligent technical use of this system is required.

From the standpoint of control, one important duty of health and food and drug officials is to make certain that all alleged vitamin D milks are always actually potent in the antirachitic substance, and this is also true of the medical milk commissions under whose certification products labelled "Vitamin D Certified Milk" are dispensed. Another duty is to require proper labelling of these products, but at present this is a rather complicated matter and might cause misunderstandings due to the methods of bio-assays and the potencies of milks produced or prepared under the several methods. A third duty is to make sure that the milks themselves are of acceptable sanitary quality.

The average health official does not have facilities for bio-assays of the vitamins in milk. These can be made only in properly equipped bio-chemical laboratories, such as exist at large universities and at some agricultural experi-

ment stations. The bio-assays should be made routinely every two or three months in the case of "yeast" milk, and possibly oftener for the other types, especially if there seems to be any fluctuation in results. Recording devices analogous to temperature control for pasteurizing machines, are being developed for irradiation processes and will serve as effective aids to control officials.

To date no scientific evidence has been advanced to show that there is danger from an excess of vitamin D in these milks, but there may be a hazard from lack of it. If the proper potency is not maintained, physicians and consumers who rely on them as antirachitics will be defrauded and public health will suffer. According to Hess,² an intake of from 20 to 24 ounces of irradiated milk containing from 50 to 56 rat units of vitamin D to the quart is satisfactory; "yeast" milk should have not less than 90 units; while cod liver oil must possess at least 250 units to be effective; and viosterol requires from 600 to 800. From these facts, it is obvious that the irradiated and "yeast" milks have certain advantages as antirachitics, especially since they are also the best dietary sources of the necessary minerals, calcium and phosphorus.

The labelling of all milks may be governed by local statutes and regulations, but the vitamin D milks should be specially labelled to show exactly what they are, and this labelling should be permitted only if potency is demonstrated. As a temporary expediency it may be suggested that as a natural milk supply, the "yeast" milk may be designated only as "Vitamin D Milk." Irradiated milk should be so labelled, with the added phrase "Vitamin D Milk," but that made by the use of a concentrate should be designated as a milk so modified. Statement of rat units or potency on labels apparently is impracticable at present. The actual grade of the milk, such as "Certified," "Grade A," etc., should also appear on the label.

Since the appearance on the market of the first vitamin D certified milk in the summer of 1931, many scientific investigations have been conducted on this type of milk and many contributions have been made to the literature on the subject. A number of valuable papers on vitamin D milk have been published in this *Journal*,⁴ while the subsequent literature has been mentioned in the recent brilliant paper by Hess.² Health officials in communities where vitamin D milk is now or is about to be distributed, should familiarize themselves with all of this valuable material, and they should be prepared to exercise zealous surveillance over these special milks, the proper use of which can do so much to promote the public health.

ASSOCIATION NEWS

ENTERTAINMENT AND INSPECTION TRIPS

INDIANAPOLIS

THERE will be feast for the mind and satisfaction for the soul for four days beginning October 9 when the American Public Health Association meets in Indianapolis.

The Entertainment Committee is planning a series of trips to interesting points, and occasions when the seriousness of the meetings may be set aside for lighter diversion. At 10:00 A.M. on Monday an inspection trip to the Purification Plant of the Indianapolis Water Company is being arranged, and at 2:30 P.M. on the same day there will be a trip to the Biological Plant of the Eli Lilly Company. This plant is approximately 20 miles east of Indianapolis on the National Road just outside the town of Greenfield where James Whitcomb Riley, the children's poet, first saw the light of day. For the visiting ladies a tea and travel talk will be given at the same hour at Sculptor's Hall, John Herron Art Institute. The speaker on this occasion will be Dr. Charles P. Emerson, a member of a commission which last year visited the Orient, and who in his interesting and inimitable style will give his impressions of that part of the world. The day's entertainment will close with music and dancing at 9:30 P.M. following the Presidential Reception.

On the morning of Tuesday, October 10, the Eli Lilly Company will take those signing up for the trip through their Indianapolis Plant, and at 2:30 P.M. buses will transport delegates and visitors to the meeting to the Indianapolis Medical Center. This Medical Center consists of a group of hospitals,

which includes the Indiana University School of Medicine, the Indiana University School of Dentistry, the Indianapolis City Hospital, the Robert W. Long General Hospital, the Coleman Maternity Hospital, and the Riley Memorial Hospital for Children.

To lovers of the American folk song a visit to Foster Hall will be of interest on Wednesday at 10:00 o'clock in the morning. Foster Hall was built by Mr. J. K. Lilly and dedicated to the memory of Stephen C. Foster who gave us such treasures as "Old Folks at Home," "Uncle Ned," "Old Kentucky Home," "Nelly Was a Lady," and other masterpieces which have traveled through the century. Foster Hall has a collection of original writings and belongings of Stephen C. Foster and is the best of its kind in the United States.

On Wednesday afternoon at 2:30 a tour of Indianapolis will take place which will offer the opportunity of seeing points of interest, which include the Scottish Rite Cathedral reputed to be the finest cathedral of its kind in the country; the national headquarters of the American Legion, home of James Whitcomb Riley, the famous motor speedway, beautiful municipal parks and playgrounds. While on this visit it is expected that there will be a 20-minute concert by the carillon of the Scottish Rite Cathedral. These chimes came from Loughborough, England, and were donated by one of Indianapolis's citizens at a cost of \$250,000. A Memorial Session at which there will be some of the survivors of the Havana Yellow Fever experiments and the

banquet will take place Wednesday evening at 6:30, following which there will again be dancing and refreshments to offset the strenuous day's activities.

An inspection of a model sewage plant in one of the smaller towns not far from Indianapolis will be made on the afternoon of Thursday, October 12, by sanitary engineers.

Transportation will be furnished for all trips, and automobiles will be available for those desiring special trips or visits. Of course there will be golf during the entire week and a special arrangement for golf by the ladies at one of the Indianapolis country clubs—and a shopping tour is also being planned for the lady visitors.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- Frank O. Alley, B.S., Box 238, Bar Harbor, Me., Health Officer
J. Leake, M.D., New Kien Bldg., Portsmouth, Va., Health Director, Norfolk-Princess Anne Counties
J. S. McBride, M.D., 300 Public Safety Bldg., Seattle, Wash., Commissioner of Health
Gavin J. Telfer, M.D., 703 California State Bldg., Los Angeles, Calif., District State Health Officer.

Laboratory Section

- Enrique E. Ecker, Ph.D., 2085 Adelbert Road, Cleveland, O., Associate Professor of Immunology, Western Reserve University
Katharine M. Howell, M.D., 2900 Ellis Ave., Chicago, Ill., Head of Department of Bacteriology and Serology, Michael Reese Hospital, Nelson Morris Memorial Institute
Donna E. Kerr, M.A., 763 Hornby St., Vancouver, B. C., Canada, Assistant Director, Provincial Board of Health Laboratories
Arthur W. Wright, M.D., 136 S. Lake Ave., Albany, N. Y., Director, Bender Hygienic Laboratory

Public Health Engineering Section

- C. Fred Berghout, B.S., 757-27 St., Ogden, Utah, Statistical Assistant
W. V. Brumbaugh, 927-15 St. N.W., Washington, D. C., Secretary, National Lime Assn.
Lincoln Continentino, C.E., Avenida Alvares Cabral 514, Belo Horizonte, Brazil, Inspector of Sanitary Engineering, Dept. of Public Health of Minas Geraes (Assoc.)
Archie B. Freeman, B.S., Box 482, Morehead City, N. C., Assistant Sanitary Engineer, State Board of Health

- William U. Gallaher, 306 W. Prospect Ave., Appleton, Wis., Chemist, Appleton Water Dept.
R. H. Lefmann, City Hall, University City, Mo., Supervisor of Sanitation
Gus H. Radebaugh, Urbana, Ill., Manager, Urbana and Champaign Sanitary District
Edward Thornton, C.E., Box 273, Katonah, N. Y., Assistant Engineer, Department of Water Supply, Gas and Electricity of New York City

Industrial Hygiene Section

- Leonidas R. Harless, M.D., Gauley Bridge, W. Va. (Assoc.)
Edward C. Holmblad, M.D., 20 W. Jackson Blvd., Chicago, Ill., Regional Chief Surgeon, Railway Express Agency

Food and Nutrition Section

- Paul L. Day, Ph.D., School of Medicine, University of Arkansas, Little Rock, Ark., Professor of Physiological Chemistry
Conrad A. Elvehjem, Ph.D., Agr. Chem. Bldg., University of Wisconsin, Madison, Wisc., Professor of Agricultural Chemistry
Fannie Krieger, Fairmont, W. Va. (Assoc.)
Winifred W. Wencke, Box 456, Logan, W. Va., District Director, American Friends Service Committee

Public Health Education Section

- Charles Auerbach, 49 St. & Grays Ave., Philadelphia, Pa., Manager, West Disinfecting Co.
Vivian Drenckhahn, C.P.H., 708 Ellicott St., Buffalo, N. Y., Health Teacher, Buffalo Tuberculosis Assn.
Rudolph H. Sundberg, M.D., 2001-4th Ave.,

San Diego, Calif., Member of staff of Rees-Stealy Clinic

Child Hygiene Section

Helen D. Bull, M.D., 817 E. State St., Ithaca, N. Y., Professor of Parent Education, Cornell University

David Goldberg, M.D., Westwood, N. J., School Physician

Florence Houghton, 1050 Koppers Bldg., Pittsburgh, Pa., Social Worker, Koppers Coal Company.

Ethel D. Owen, M.D., 909 Hyde St., San Francisco, Calif., Supervising School Work for Prevention of Tuberculosis

Carroll E. Palmer, M.D., 615 N. Wolfe St., Baltimore, Md., Instructor, Dept. of Biostatistics, School of Hygiene and Public Health, Johns Hopkins University

Public Health Nursing Section

Letha S. Allen, R.N., 69 Main St., Tuckahoe, N. Y., Director, Public Health Nursing Organization

Montserrat Bipol, Paris 179, Barcelona, Spain (Assoc.)

E. Pauline Bledsoe, McPherson County Red Cross, McPherson, Kans., County Public Health Nurse

Maria L. Caperochipi, Hersani 19-20, San Sebastian, Spain, Nurse (Assoc.)

Dorothy J. Carter, R.N., N.O.P.H.N., 450-7th Ave., New York, N. Y., Assistant Director

Mary A. Helterline, R.N., 42 W. Maiden St., Washington, Pa., Supervisor, American Red Cross Nursing Service

Eleanor L. Kennedy, R.N., State Bureau of Public Health, Santa Fe, New Mexico, State Supervisor of Public Health Nursing

Donna Pearce, R.N., State Dept. of Public Health, Nashville, Tenn., State Supervising Nurse

Epidemiology Section

Elsie F. Dochterman, A.B., 611 W. 171 St., New York, N. Y., Research Assistant in Epidemiology, De Lamar Institute of Public Health, College of Phys. & Surg., Columbia Univ.

Henry C. Ricks, M.D., C.P.H., State Board of Health, Jackson, Miss., Director, Bureau of County Work and Epidemiology

P. K. Telford, M.D., 1349 Warner Ave., Los Angeles, Calif., Chief, Division of Tuberculosis, Los Angeles County Health Department

Unaffiliated

Lars Gulbrandsen, M.D., 1853 W. Polk St., Urbana, Ill., Instructor, Department of Bacteriology and Preventive Medicine, University of Illinois.

DECEASED MEMBERS

Prof. F. P. Gorham, Providence, R. I., Elected Member 1899, Fellow 1922.

Dr. E. M. Pickens, College Park, Md., Elected Member 1927, Fellow 1930.

Magnus W. Alexander, New York, N. Y., Elected Member 1928 (Associate).

John W. Carey, Barnhardt, Mo., Elected Member 1930.

Calvin L. Cooper, M.D., Kansas City, Mo., Elected Member 1929.

Gideon J. Ferreira, M.D., Duluth, Minn., Elected Member 1928.

J. S. Horner, M.D., W. Pawlet, Vt., Elected Member 1921.

C. Wilson Miller, Columbia, S. C., Elected Member 1928.

J. O. Skinner, M.D., Washington, D. C., Elected Member 1917.

Francis H. Slack, M.D., Coolidge Corner, Mass., Elected Member 1905.

Agnes Walker, M.D., Bolinas, Calif., Elected Member 1919.

Gordon Wilson, M.D., Baltimore, Md., Elected Member 1919.

James W. Wiltse, M.D., Albany, N. Y., Elected Member 1926.

BACK NUMBERS OF JOURNAL NEEDED

Due to unusual demands for the July, 1932, August, 1932, September, 1932, numbers of the *Journal*, and for the January, 1933, and February, 1933, numbers, the Executive Office of the A.P.H.A. is in need of as many copies of these issues as are obtainable. It will be greatly appreciated if members who can spare these *Journals* will send them to headquarters. Those complying with this request will be reimbursed for the postage used in mailing.

CORRECTION

In the paper, "Resident Mortality from Tuberculosis in Urban and Rural New York According to Age, Sex, Color, and General Nativity," by Elizabeth Parkhurst, on pages 903 and 906 of the September *Journal*, are two charts, above which should appear the words "Male" on the left, and "Female" on the right.

PUBLIC HEALTH ADMINISTRATION

Pittsburgh, Pa.—The August issue of *Pittsburgh's Health* contains the first résumé of the activities of the health department which has been printed for many years. The report gives a very complete description of the organization of the department, the number employed in each service, and a numerical résumé of the activities for the past year. In Pennsylvania, vaccination against smallpox is compulsory for all school children. This service is performed by the school physician only when so desired by parents unable to pay. School physicians administer toxoid and give the Schick test. It is estimated that by the end of the year 52 per cent of the children of school age had been immunized.

New Haven, Conn.—The July *Bulletin* contains a résumé of the health conditions in New Haven for the first half of the year 1933. For the first 6 months of 1933 there was a total of 1,019 deaths compared with 945 for a similar period during the preceding year. The death rate has increased from 11.6 in 1932 to 12.5 in 1933. Influenza and pneumonia are largely accountable for the increase. An outstanding feature is the absence of any deaths from the common communicable diseases as compared to a total of 5 for 1932. Cases of diphtheria have totalled but 2 for each of the years and but 5 carriers have been found in 1933 as compared to the period in 1932 when 27 were found. A most notable feature for the 1933 period is the absence of any typhoid fever case.

Shorewood, Wis.—This residential suburb of Milwaukee, with an esti-

mated population of 14,000 in 1932, continues to be one of the honor cities in the annual Inter-Chamber Health Conservation Contest conducted by the U. S. Chamber of Commerce. The annual report contains a rather complete description of the activities of the department, well illustrated. It is reported that over 90 per cent of the school children are protected against diphtheria and smallpox and that more than 80 per cent of infants and children of preschool age have received diphtheria protection. Not a single case of diphtheria or smallpox has been reported in Shorewood during the past 3 years. It is the policy to give the Schick test to every school child before administering toxoid or toxin-antitoxin.

For the sixth consecutive year the report contains a self appraisal of the community health service. The weighted score is now 945 points in a possible 1,000. It is stated that Shorewood is penalized since it is a high grade residential suburb, but the self appraisal endeavors to make reasonable allowance for these phases of the measuring stick which cannot be applied without interpretation to non-industrial communities.

Diphtheria Protection in New York—The *Health News* of the New York State Health Department for August 7 reports that more than 1,000,000 upstate children have received either three doses of toxin-antitoxin or two inoculations of toxoid. One-fourth of the protected children were under 5 years of age at the time of inoculation. Since 1926 the number of deaths from diphtheria in New York State, exclusive of New York City, has

shown a steady decline from 250 to 59. The deaths among children under 5 years of age have been reduced from 123 to 22. To increase the number of preschool children protected requires something in addition to the usual publicity methods. The home visitation by nurses has proved productive of results.

Hygienic Institute—The 18th department of health report for the district comprising La Salle, Peru, and Oglesby, Ill., for the year 1932, shows a per capita expenditure of 90 cents as contrasted with \$1.41 for the previous year. A fairly large proportion of the income was derived from an endowment provided for this area with a population of 26,208. The Institute is governed by a board of 5 trustees who select the full-time medical director.

Several illustrations of coöperation

among agencies are noted. The Tri-City Tuberculosis Society closely affiliates with the Institute and furnishes a nurse, while the Institute equips the nurse with a car and directs her activities to avoid duplication. The three cities contribute to the sanitary program and two boards of education aid with the school nursing. By contract with the Metropolitan Life Insurance Company, the Institute does the bedside nursing work for policy holders. "This work coincidentally helps the Institute to register many prenatal cases, which furnishes the very beginning for public health work. This company also distributes, yearly, thousands of pamphlets valuable to public health." There is also close coöperation with the La Salle-Peru township high school, Tri-City Family Welfare Society, and relief agencies, in their various health endeavors.

LABORATORY

ANTIGENIC VALUE OF COMMERCIAL DIPHTHERIA TOXOIDS*

WILLIAM LEVIN, DR.P.H., F.A.P.H.A. AND HELEN A. CARY, M.D.

*Hygienic Laboratory, State Board of Health, Portland, Ore.; and
Medical Director, City Schools, Portland, Ore.*

THE use of toxoid in immunization against diphtheria has had wide application in the past few years, and in some communities has entirely replaced the use of toxin-antitoxin. The preference for toxoid has been attributed to its better immunizing effects and, by some, to the smaller number of injections necessary for immunization. Evidence has accumulated on the effectiveness of toxoid as an immunizing

agent. Park and Schroder¹ state: "The immunizing effects of our best toxoid have been better than from the best properly standardized toxin-antitoxin." Harrison² believes that toxoid is the best agent for immunizing children 6 years and under. Many other workers, both in this country and abroad are enthusiastic in their reports on the efficacy of toxoid as an immunizing agent.

There has been less agreement, however, on the number of doses as well as on the time interval between doses required for immunization. Ramon³

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27, 1932.

uses 0.5 c.c. for the first dose; 1.0 c.c., 3 weeks later, for the second dose, and 1.5 c.c., 15 days later, for the third dose. Park recommends 3 doses of 0.5 c.c. given at weekly intervals. Most manufacturers in the United States recommend that the toxoid be given in two 1.0 c.c. doses at an interval of 3 or 4 weeks. The potency of the toxoid must be known before any conclusions can be drawn as to the size and number of doses required for immunization. Commercial toxoids now on the market specify the dosage; no information, however, is given regarding their potency.

The potency of a toxoid as expressed by its antigenic value, may be determined approximately by the Ramon flocculation test, or more certainly by the guinea pig protection test. In the former, a standardized antitoxic diphtheria serum is brought in contact in suitable proportions with the toxoid. The reaction, characterized by the formation of flocculi, may be expressed in terms of flocculating units per c.c. The determination of the potency of toxoid by the guinea pig method is required by the National Institute of Health for toxoid manufactured or to be sold in the United States. The minimum protection must be such that the initial human dose of toxoid will immunize 80 per cent of the guinea pigs in 6 weeks, so that 5 m.l.d.'s of diphtheria toxin will fail to kill in 10 days.

Ramon used toxoids of at least 10 antigenic or flocculating units per c.c. Park and his coworkers are using toxoids which average 10 antigenic units per c.c. Immunity with such toxoids has been obtained in from 94 to 98 per cent of cases. Povitzky,⁴ in examining toxoids from different manufacturers found wide variation in antigenic values as determined by the flocculation test. Some toxoids had less than 1 antigenic unit; others from 4.2 to 7 per c.c.

To test the efficacy of several

brands of diphtheria toxoid sold in Oregon, a series of experiments was conducted which included the determination of the antigenic values of each toxoid, as well as the actual percentage of children immunized by it.

Diphtheria toxoids A, B, C, D, and E were obtained in the open market. Each lot was divided into 3 portions; one was sent to Dr. Povitzky, of the Bureau of Laboratories, New York City Health Department, for the determination of the flocculation values; one was used in the guinea pig protection tests; and one was used in the immunization of children.

The flocculation values as reported by Dr. Povitzky are given in Table I.

TABLE I
FLOCCULATION UNITS OF COMMERCIAL
DIPHThERIA TOXOIDS

| <i>Toxoid</i> | <i>Units per c.c.</i> |
|---------------|-----------------------|
| A | 8.9 |
| B | 3.4-3.8 |
| C | 5.8 |
| D | Around 2 |
| E | Around 2 |

The guinea pig protection tests were made in accordance with the requirements of the National Institute of Health, the only variation being that half of the immunized animals were injected with 5 m.l.d.'s and the other half with 20 m.l.d.'s of diphtheria toxin. Fifty guinea pigs of an average weight of 301 gm. were divided into 5 lots of 10 each. Each pig in the lot was injected, subcutaneously, with 1 c.c. (the initial human dose) of the toxoid under investigation. At the expiration of 6 weeks half of each lot of pigs received 5 m.l.d.'s, and half, 20 m.l.d.'s of diphtheria toxin. Four pigs died following the injection of toxoid; 1 died 40 days after injection with toxoid A; 1, 25 days; and 1, 29 days after injection with toxoid B; and 1, 40 days after injection with toxoid C. Death in all was due to pneumonia.

| Control | 1 | 1 | — | — | — | — | — | — | — | — | — | 0 | 0 |

Tables II and III give the results of the guinea pig protection tests.

Post-mortem findings on the guinea pigs dying as the result of the toxin injection indicated that death in all cases was due to diphtheritic toxemia, except possibly in 1 of the A Group since evidence of pneumonia was found in 1 which died on the 8th day following the injection of 20 m.l.d. of diphtheria toxin.

Immunization of children with toxoid was limited as far as possible to those within the 10-year age group. It was found necessary, however to include some of a higher age group. A preliminary Schick test was given to 572 children 15 years and under, and to 88

adults, none of whom, so far as could be determined, had had diphtheria or had been immunized against it either with toxin-antitoxin or toxoid. The results are given in Table IV.

Of the 482 Schick positive reactors 467 were given the initial 1 c.c. dose of toxoid—441 children and 26 adults. Each lot of toxoid was given to approximately the same number of children. Lots A, C, and D were given to children in the Portland public and parochial schools; and lots B and E were given to those in the Salem public schools; and to children and adults in the State Institution for the Feeble-Minded, Salem.

A few children who gave a combined

TABLE IV

RESULTS OF PRELIMINARY SCHICK TEST

| Age Group | Total Number Tested | Schick Positive | Per cent Non-Immune |
|-------------|---------------------|-----------------|---------------------|
| 4-5 | 9 | 8 | 88.9 |
| 6-10 | 408 | 363 | 88.9 |
| 11-15 | 155 | 85 | 54.8 |
| 16 and over | 88 | 26 | 29.5 |

(protein) Schick reaction were excluded from the toxoid immunization and were given toxin toxin-antitoxin instead. Three weeks after the first toxoid injection a second injection of 1 c.c. was given. While there were a few local reactions following the injection of the toxoid, there was a marked absence of systemic reactions. This was in contrast to what followed the administration of toxoid by one of us (H. A. C.) to children without a preliminary Schick or sensitization test, when very severe local and at times systemic reactions resulted.

Three months following the second toxoid injection, the final Schick test was given. Removals, illness, and other causes were responsible for a large reduction in the number of those given the test for acquired immunity. Of 467 given the initial dose of toxoid, only 380 were available for and were given the final Schick test. Table V gives the results of the toxoid immunization in children between the ages of 5 and 15 years.

A total of 26 Schick-positive persons ranging in age from 16 to 50 years were also given toxoid B and 2 of these gave a positive Schick on the re-test. Of the 71 persons given toxoid B, 95.8 per cent were immunized. Nineteen children of the 5-15 year age group who did not get a preliminary Schick test were given two 1 c.c. doses of toxoid E, with a 3-week interval between doses; 16, or 84.2 per cent, were shown to be immune after 3 months. Twenty-eight

children in the same age group, also without a preliminary Schick test, were given two 1 c.c. doses of toxoid B with a 3-week interval between doses; 27 or 96.4 per cent were shown to be immune after 3 months.

A comparison of the antigenic values of the toxoids tested by the various methods already outlined is given in Table VI.

According to federal standards it appears that only toxoid B and C met the requirements of an 80 per cent survival against 5 m.l.d.'s diphtheria toxin. Toxoid A, with a high flocculation value, showed up poorly both in the guinea pig test and in the percentage of immunes produced in children. The manufacturers of toxoid A, stated:

This toxoid was preserved with phenol and there has accumulated considerable evidence that the phenol as a preservative at times interferes with the immunizing property of the toxoid, without affecting more than in a light degree at least the flocculating value. We are discontinuing the use of phenol as a preservative.

With the exception of toxoid A, the results show a fair correlation between the antigenic values of the various toxoids obtained with the Ramon flocculation test and with the guinea pig protection test. The latter method, however, gave a truer index of the potency as expressed in the immunity conferred on children. The recent advances made in the concentration and purification of toxoid by precipitation with alum ^(1, 5, 6) fortify our belief

TABLE V
IMMUNITY CONFERRED IN CHILDREN 5 TO 15 YEARS BY TWO DOSES OF 1 C.C. TOXOID
INJECTED AT 3-WEEK INTERVAL

| Toxoid | No. of Children Re-Schicked | No. of Schick Reactors | | Per cent Immunized |
|--------|--------------------------------|------------------------|----------|--------------------|
| | | Positive | Negative | |
| A | 73 | 13 | 60 | 82.2 |
| B | 45 | 1 | 44 | 97.8 |
| C | 79 | 0 | 79 | 100.0 |
| D | 77 | 12 | 65 | 84.4 |
| E | 80 | 8 | 72 | 90.0 |

TABLE VI

COMPARATIVE ANTIGENIC VALUES OF TOXOIDS OBTAINED BY FLOCCULATION, GUINEA PIG PROTECTION AND HUMAN INJECTION METHODS

| Toxoid | Date of Expiration 1933 | Diluted | Flocculation Value | Guinea Pig Protection Test Per cent Survival | | Per cent Children Immunized |
|--------|----------------------------|-----------|-----------------------|---|-----------|-----------------------------------|
| | | | | 5 m.l.d. | 20 m.l.d. | |
| A | May 4 | Undiluted | 8.9 | 60 | 50 | 82.2 |
| B | May 15 | 1 + 1 | 3.4-3.8 | 75 | 25 | 97.8 |
| C | May 30 | Undiluted | 5.8 | 80 | 75 | 100.0 |
| D | June 8 | 1 + 3 | Around 2 | 20 | 0 | 84.4 |
| E | Apr. 26 | 1 + 1 | Around 2 | 40 | 60 | 90.0 |

that the present federal minimum standards of potency are too low. The use of the flocculation test for the determination of the suitability of a toxin for the production of a toxoid is unquestioned. Our experiments, however, indicate that the flocculation value in itself is not a sufficiently reliable index of the potency of a toxoid, and should, therefore, not replace the guinea pig method. The use of both methods for the determination of the antigenic value is recommended.

A potent toxoid should be expected to give from 95 to 100 per cent immunity. One of the surprises in our experiments was the high degree of immunity conferred by toxoids of low antigenic values. Carefully controlled immunization tests on Oregon children with toxin-antitoxin by one of us (W. L.) never yielded a degree of immunity higher than 80 per cent. At the same time, it must not be overlooked that in mass immunization toxin-antitoxin may be given with impunity, whereas, in the administration of toxoid the problem of protein reactions presents itself. Unquestionably, with the attainment of a pure toxoid, that problem may be solved.

Our experiments indicate that two doses of a potent toxoid given at an interval of 3 weeks, may be expected to give a high percentage of immunes. It is interesting to note that a diluted as well as an undiluted toxoid gave good results. Park believes that if the

dosage is 0.5 c.c. (undiluted), 3 doses at weekly intervals should be given. The standards of potency of the National Institute of Health require that "the maximum human dose shall not exceed 1 c.c. of undiluted toxoid."

Further studies on toxoid, particularly on its standardization, are highly imperative. The suggestion of Schmidt of Copenhagen that the antigenic unit be termed "Immunizing Unit" is worthy of serious consideration. Once the potency of such a unit has been agreed upon and defined, the manufacturers of toxoid should be required to state on their labels the potency of their product in terms of "I. U." Until such time we must rely upon a Schick re-test 3 or 4 months after the last toxoid injection.

SUMMARY AND CONCLUSIONS

Five commercial makes of toxoid were tested for their antigenic values by the Ramon flocculation test, by guinea pig protection tests, and by human experiment. Considerable variation in their antigenic values was found. There was fair correlation between the antigenic values of the various toxoids obtained by the Ramon flocculation test and by the guinea pig protection method, the latter method, however, paralleled more closely the results obtained in the immunization of children.

A total of 354 children between the ages of 5 and 15 were given two injections of 1 c.c. each of toxoid at a 3-week

interval. The percentage of children who became immune ran from 82.2 to 100. The results warrant the belief that a potent toxoid should give from 95 per cent to 100 per cent immunization.

Both the flocculation and guinea pig tests should be used in the determination of the antigenic value of a toxoid. The present minimum potency standards of the National Institute of Health should be raised, and steps should be taken to define and adopt a standard potency unit.

Since there is considerable variation

in the antigenic value of toxoids now on the market, a Schick re-test 3 or 4 months after the last immunizing injection is highly recommended.

VITAL STATISTICS

Vital Statistics for Canada, 1932—According to a preliminary report from the Dominion Bureau of Statistics, there were 235,143 live births in Canada (exclusive of the Yukon and Northwest territories) in 1932, compared with 240,473 in 1931. The birth rate for 1932 was 22.4 (per 1,000 population); the corresponding figure for 1931 was 23.2. A marriage rate of 6.0 (per 1,000 population) was registered in 1932; in 1931, 6.4. In 1932, deaths from all causes numbered 104,190, resulting in a mortality of 9.9 (per 100,000 population)—as against 104,517 deaths and a rate of 10.1 in 1931. The 1932 death rate from all causes showed a decline of 13 per cent from the rate (11.4) recorded in 1926 when the present registration area of 9 provinces was established.

The low general mortality rate for 1932 was effected mainly through declines in such individual causes of death as tuberculosis which showed a death rate of 68 per 100,000 population in 1932 (74 in 1931); diarrhea and enteritis, 36 in 1932 (50 in 1931); diseases of early infancy, 76 in 1932 (87

in 1931); and violent deaths—63 in 1932 (69 in 1931). Fortunately the effect of the decreases in the foregoing death rates was not nullified by increased death rates in 1932 from diseases of the heart—146 per 100,000 population (132 in 1931); diseases of the arteries, 65 (58 in 1931); influenza, 40 (31 in 1931); nephritis, 54 (50 in 1931); and cancer, 95 (92 in 1931).—Tables from—*Preliminary Report of Vital Statistics of Canada, 1932*, pp. 2, 3, 10; *Preliminary Report of Vital Statistics of Canada, 1931*, pp. 3, 10.

Births by Nativity of Mother in Pennsylvania in 1932—A total of 168,553 live births was reported in Pennsylvania in 1932. Live births to native born mothers numbered 147,724, or 88 per cent of the total recorded; those to foreign born mothers totaled 20,744. There were also 85 birth certificates on which the nativity of the mothers was not stated.

During the past 10 years there has been a decided decline in the number of births to foreign born mothers in Pennsylvania. Foreign born mothers

accounted for 28 per cent of the total live births in 1922, 20 per cent in 1927, and 12 per cent in 1932; this ratio has dropped 57 per cent in the period 1922 to 1932. Of the live births to mothers of foreign nativity, 5,666 or 27.3 per cent were to those of Italian birth; 3,578 or 17.3 per cent to Austrian mothers; 2,319 or 11.2 per cent to Polish; 1,561 or 7.5 per cent to Russian; 1,443 or 7.0 per cent to Irish; 1,328 or 6.4 per cent to English, Scotch, and Welsh; and the remaining 4,829 or 23.3 per cent to German, Greek, Scandinavian and other foreign nationalities.—Pennsylvania Dept. of Health. *Vital Stat. Bull.* 8:5 (Aug.), 1933.

Scottish Vital Statistics for 1932—Reports just published show that the general death rate in Scotland for the year 1932 increased slightly over the rate of 13.26 per 1,000 population which was recorded in 1931. The rate in 1932 was 13.5. Infant mortality also increased in 1932, a rate of 86 deaths under 1 year per 1,000 births being recorded that year in comparison with 82 in 1931 and an average of 85 for the previous 5 years. However, the death rate from tuberculosis reached a record low figure of 84 per 100,000 population in 1932 as against 87 in 1931.

The birth rate in Scotland, which has been declining constantly, dropped in 1932 to a new low rate of 18.6 per 1,000 population. This is approximately half the rate (35.62) recorded in 1876, the year showing the maximum birth rate in Scotland.

In a discussion of the causes of the decline in the birth rate, it is pointed out that it cannot be explained by a diminution of the marriage rate or increase of the average age on marriage. From 1861 to 1901 the average age on marriage showed little variation—from 27.2 to 27.5 years. Since 1901 there has been but a slight increase, the average age at marriage being 27.8 in

1930. The decline in the birth rate started in 1876, while the increase in age at the time of marriage began much more recently. Moreover, the married population at the censuses of 1901, 1911, and 1921 was, as regards age, more favorably constituted for a high rate than in 1885.—*J.A.M.A.* 101:457 (Aug. 5), 1933.

Where and How Men Get Hurt—

The chance of accident to the man on the street is less than is generally supposed. Out of an aggregate number of 117,477 injuries studied by the Accident and Health Department of the Metropolitan Life Insurance Company, there were only 9,078, or 7.7 per cent of the total, that happened while walking on streets and highways. The public travel accident hazard is of even less importance; for only 2.2 per cent of the injuries happened on buses, taxicabs, street cars, trains, boats, airplanes and other public conveyances. These figures relate to a group of persons who are employed in non-hazardous occupations and whose ages range between 18 and 65 years.

The vast majority of accidents occur in places which the average man seldom associates with danger—at home, in offices, in stores and in sports and games. Out of more than 117,000 injuries that were studied, close to 17,000 occurred in homes or on home premises; another 40,000 occurred within the apparently safe confines of office buildings, hotels, stores, clubs, and other public structures. Altogether, 49 per cent of all the accidents occurred inside of buildings or in private grounds where people might feel that they were comparatively safe from harm. Then, there were nearly 13,000 accidents, or 11 per cent of the total, that occurred in the common games and sports that are indulged in by the average man. These include such supposedly harmless sports as tennis, golf, skating, and even danc-

ing. Over 25,000 injuries, or 21 per cent of the total, occurred to persons riding in privately owned automobiles. The main causes of these automobile accidents were collisions with other cars, skidding, and caring for the automobiles.

A considerable number of injuries were sustained in very ordinary ways. First, missteps and falls caused nearly one-third of the total injuries. These occurred most commonly on sidewalks, on stairs, over rugs and over other objects on floors. Getting in or out of bed is hardly to be considered a dangerous activity; and yet 76 men fell and were injured in this manner. The ordinary bathtub or shower, which in the past was accused of many casualties, accounted for only 557, or less than one-half of 1 per cent. The second important group of injuries were from broken glass, nails, other sharp instruments, and splinters. These make up 18 per cent of the total. Third in order of importance, with 17 per cent of the total, were injuries by vehicles. In this class the automobile is the chief offender. Together, these three broad classes of injuries accounted for 66 per cent of the total. The remaining 34 per cent were due to being struck by falling or flying objects, to colliding with other persons or objects, to burns or explosions, to being caught in doors and windows and to a variety of other happenings.

Injuries are, for the most part, due to trivial and minor mishaps which can readily be avoided. In the aggregate, however, these preventable accidents cause an immense amount of discomfort, as well as the waste of huge sums of money because of time lost from work and the cost of medical care.—Met. Life Ins. Co. *Stat. Bull.* 14:8–10 (July), 1933.

Vital Statistics Records for New Jersey for 1932—In 1932, New Jersey

recorded a general death rate of 10.11 per 1,000 population in comparison with the rate of 10.63 recorded in both 1930 and 1931. The rate of 10.63 had previously been the lowest death rate from all causes registered in the state since the establishment of the State Department of Health.

The decline to this new low figure was aided by the 1932 death rate from typhoid fever (0.7 per 100,000 population), diphtheria (2.2 per 100,000), tuberculosis (60.6 per 100,000); and deaths under 1 year of age (49.6 per 1,000 live births)—which were the lowest rates ever recorded in the state for these individual causes of death.

Since 1912 the annual death rate from typhoid fever in New Jersey has not exceeded 10 per 100,000 population—a rate far removed from the maximum death rate of 74.3 recorded in 1882; the highest mortality rate from this disease during the past 5 years was 1.7 (1928). Diphtheria has also declined greatly. In 1888 this cause of death exacted a toll of 148 per 100,000 population; during the decade beginning with 1900, the rate declined from 48 to 25; the following decade showed a drop to 18 per 100,000; finally the figure fell to 2.2 in 1932. The 1932 death rate from all forms of tuberculosis (60.6 per 100,000) is very favorable in comparison with the rate of 90.1 which was recorded for this disease only 8 years ago.

Puerperal causes showed a death rate of 5.7 per 1,000 live births in 1932 compared with 5.9 in 1931. Deaths due to accidents in which moving automobiles were involved totaled 1,158 in 1932 as against 1,302 for 1931.

In 1932 approximately 62,250 births were recorded, equivalent to a rate of 14.6 per 1,000 population. The total number of births reported showed a decline of approximately 2,000 from the 1931 figure.—New Jersey *Pub. Health News*. 17:143–44 (July-Aug.), 1933.

PUBLIC HEALTH ENGINEERING

A HYPOCHLORITE FEEDING DEVICE*

FRANK R. SHAW, ROBERT W. KEHR AND EDWIN T. MATTHEWS

Sanitary Engineer; Assistant Sanitary Engineer; and Sanitary Engineering Assistant, U. S. Public Health Service, Chicago, Ill.

THE principle involved in this hypochlorite feeding device is that of syphoning the hypochlorite solution from a container or containers and delivering it through a stop-cock, a capillary tube and a chlorine-resisting hose to the point of application. This principle is illustrated in the accompanying sketches of two forms of the device. Since a 2 mm. stop-cock and a $\frac{1}{4}$ " diameter hose are used as standard practice, the size and length of the capillary tubing serves as the restriction or orifice to effect control of the flow. A wide range of flows may be established by the use of different sizes and different lengths of capillary tubing. The period of time during which the hypochlorite will flow continuously can be increased at will by using a larger container or additional like containers and connecting them by syphons.

Where very accurate administration of hypochlorite is desired, there could be installed a constant level box at a distance of 1' or more below the bottom of the container or containers. Under such an arrangement, the contents of the hypochlorite container or containers would be syphoned to the constant level box by means of an unrestricted $\frac{1}{4}$ " diameter hose attached to a float valve on the constant level box. From the constant level box the hypochlorite

would flow to the point of application through the 2 mm. stop-cock, the proper capillary tubing and the necessary $\frac{1}{4}$ " hose. In this case, the total head would be measured from the surface of the hypochlorite in the constant level box. It should be borne in mind that the constant level box and all of its working parts must be made of materials non-corrosive to chlorine, such as glass, hard rubber or sterling silver.

TECHNICAL FACTORS

The device, without the provision of a constant level box, was originally developed for use in super-chlorination and in connection with filtration and activated carbon chlorine removal. With such an application, one would not be concerned about the concurrent reduction of flow due to the ever increasing syphon lift as the hypochlorite container emptied; but would simply arrange for the desired chlorine dosage under the conditions of the lowest rate of flow. It is obvious that the reduction in flow is a function of the total head under which the apparatus is working. Calibration of various lengths of various sizes of capillary tubing under different heads indicated the per-

TABLE I

| Total Head | Per Cent Decrease in Flow |
|------------|---------------------------|
| 3' | 22 |
| 5' | 13 |
| 8' | 6 |
| 12' | 4 |
| 17' | 3 |

* To be read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

centages of decrease in flow from a 5 gal. pyrex bottle between the first 1,000 c.c. and the last 1,000 c.c. (Table I).

These figures suggest the desirability of operating under a head of 5' or more so as to minimize the decrease in the rate of flow. These figures also warrant the opinion that the application of the device need not be limited to use in conjunction with activated carbon dechlorination, especially when operated under heads of from 5' to 17' or more. For a 0.5 p.p.m. minimum dose, there would be created a maximum dose of 0.515 p.p.m. under a 17' head; 0.52 p.p.m. under a 12' head; 0.53 p.p.m. under an 8' head and 0.565 p.p.m. under a 5' head.

When the device operates under gravity flow the total head is the distance from the surface of the hypochlorite in the container to the upper end of the capillary tubing. When the hypochlorite is applied to the suction of a pump the total head is the static suction lift of the pump plus the friction losses in the pump's suction pipe, plus the distance from the top of the capillary tubing to the surface of the hypochlorite.

The time required to empty the hypochlorite container is governed by the capillary tubing. In every case the hours of flow are determined by the period of time desired between recharging of the hypochlorite container. In the case of a pump operating 5 hours each day, a capillary tube of such size and length would be selected as to require 5 hours or slightly more to empty the hypochlorite container under the particular head which pertains to the problem.

To establish a guide for the selection of the proper size and proper length of capillary tubing, certain lengths of the several sizes of capillary tubing were calibrated as to time while flowing under certain heads. The water used in this calibration was Chicago City water

which is unfiltered Lake Michigan water and therefore high in its plankton content. The results of this calibration for 5 gal. of water appear under the heading of "Hours of Flow." With filtered or well water and a clear hypochlorite solution, longer hours of flow might be established by using $\frac{1}{2}$ mm. capillary tubing.

From this tabulation, it is easy to select the size and length of capillary tubing for any particular installation or from it determine the number of 5 gal. units needed to establish the time of flow desired. If the total head, either by gravity flow or pump suction, is 8' and it is desired to have a 5 gal. bottle last 4 hours, then one has the choice of a 4" length of $\frac{3}{4}$ mm. or a 15" length of 1 mm. capillary tubing. If an 8 hour flow is desired under the same conditions, then a 10 gal. container or two 5 gal. containers connected by a syphon would be installed.

A container of any size may be used in connection with a constant level box and without such a box where the percentage reduction in flow is not a factor, such as where chlorine taste is not objectionable or where the chlorine is removed by activated carbon. If the depth of the hypochlorite in the container is no greater than the depth of the hypochlorite in a 5 gal. pyrex bottle then the above percentages of reduction in flow would hold true regardless of the quantity of hypochlorite involved. If the depth of the hypochlorite is appreciably greater than that in a 5 gal. pyrex bottle then a greater percentage of change in flow will occur.

The temperature of the water used in the calibration of the capillary tubing was between 19° C. and 22° C. It was thought that the temperature of the liquid may have a noteworthy influence on the flow. Tests under different heads and under water temperatures as high as 40° C. revealed an average increase

chlorite and effecting a dose of 0.5 p.p.m., flows of from 915 to 5,500 gal. per minute under heads of 3' to 17' respectively may be treated for periods of time of 27 hours and 4.5 hours respectively with one 5 gal. container. Of course it is obvious that with regular treatment over a considerable part of a day there is a rate of flow beyond which it would not be economical to use hypochlorite.

FORMULA FOR COMPUTING QUANTITY OF HYPOCHLORITE

H. Number of cubic centimeters of hypochlorite needed for each charging of the hypochlorite feeder

G. Rate of flow to be treated in gallons per minute

T. Time of flow from hypochlorite container in hours

d. Desired chlorine dosage in parts per million (pounds per million pounds)

p. Percentage strength of hypochlorite stock solution to be used, expressed as a decimal.

$$0.22712 \times G \times T \times d$$

$$H = \frac{\quad}{p}$$

CONVERSION TABLE

| | | | | |
|----------|---|--------------|---|------------------|
| 1 gallon | = | 3,785.4 c.c. | = | 128 fluid ounces |
| 1 quart | = | 946.4 c.c. | = | 32 fluid ounces |
| 1 pint | = | 473.2 c.c. | = | 16 fluid ounces |
| 1 gill | = | 118.3 c.c. | = | 4 fluid ounces |

DESCRIPTION OF THE HYPOCHLORITE FEEDER

For the purpose of identification the initials SKM have been assigned to this device. Two types of the device have been developed, one known as the SKM-1 and the other as SKM-2.

An illustration of each type appears elsewhere.

SKM-1—The SKM-1, which involves the syphoning of the hypochlorite solution from a 5 gal. bottle or carboy, was designed primarily for use on steamships where the rolling and pitching of the vessel required that the hypochlorite container be all enclosed. It also has a feature by which the syphon can be started by means of an air pressure bulb.

This type is also especially applicable where the rate of flow is sufficiently small to permit the measuring of the hypochlorite stock solution to be introduced into the bottle by means of a graduated 125 c.c. or 250 c.c. separatory funnel.

The equipment needed for this device is standard laboratory ware and may be secured from any large dealer. However, for purposes of identification, the numbers appearing in Catalogue C-227 of the Central Scientific Company, 460 Ohio Street, Chicago, Ill., and elsewhere, are given. The index letters appear on the illustration.

LIST OF EQUIPMENT—HYPOCHLORITE FEEDER SKM-1

From Central Scientific Company (or other dealer)

Numbers refer to catalogue C-227

A. Rubber stopper, one hole, to fit half-way into funnel "B." #11572B

B. Funnel, separatory, pyrex, cylindrical, etc., 250 c.c. capacity. #6161

C, D & E. Glass tubing, combustion, pyrex, std. wall, 8 mm. outside diameter, bent as follows: #7206X

| | Short Leg | Long Leg | Diameter of Bend |
|-------------|--------------|-------------|---------------------|
| C. (L tube) | 2" | 2" | 3/4" |
| D. (U tube) | 1" | 2" | 3/4" |
| E. (U tube) | 1" | 20 1/2" | 3/4" |

F. Rubber tubing, black, pure gum, heavy wall. #11596-1/4"

G. Rubber stopper with 4-7 mm. diameter holes on right angles axes 3/16" clear of edge of smaller side. #11572A X Size 12

H. Bottle, pyrex glass, narrow mouth, 5 gal. #1604

J. Tube, connecting, glass, T-shape, O.D. 3/16". #14006A

K. Rubber bulb with metal valve for pressure only. #11530

L. Stop-cock, pyrex glass, straight bore of 2 mm. #12909

N. Glass tubing, capillary, pyrex, gauged accurately both ends of size and length for particular installation. #7203 (Purchaser should select from tabulation of hours of flow under different heads.)

O. Cylinder, graduated in 1 c.c., capacity 100 c.c. #3659KA

P. Color comparator tube, Nessler, A.P.H.A.

Std., tall form with rubber stopper to fit. #3026B

Q. Pipette, 1 c.c. capacity, graduated in tenths. #10506KC

R. Beaker, pyrex glass, usual tall form with lip, 300 c.c. capacity. #1136

S, T, U, V & W. Lamotte Enslow Comparator parts. (Central Scientific Co.)

S. Ampule of distilled water

T. Ampule of 0.2 p.p.m. color std.

U. Ampule of 1.0 p.p.m. color std.

V. (3) Test tubes for set.

W. 100 c.c. orthotoluidine (use 0.5 c.c. for test)

From Most Convenient Source

Z. Chlorine resisting hose, medium wall, $\frac{1}{4}$ " inside diameter

NOTE: There should be purchased at the outset an extra or spare of all glass and earthenware parts, four to six pieces of capillary tubing of the size and length needed, 12' of hose "F" and the proper length of hose "Z" to reach the point of application.

SKM-2—The SKM-2, which involves the syphoning of the hypochlorite solution from one or more 10 gal. crocks, was designed for those cases where the device would not be subject to motion and where a considerable flow of water is treated and a large quantity of the stock solution of hypochlorite is introduced into the hypochlorite feeder. Where more than a 10 gal. quantity is required to establish flow for the entire period of treatment, two or more 10 gal. crocks may be connected together by syphons. The equipment needed for the SKM-2 is as follows:

From Central Scientific Company (or other dealer)

Numbers refer to catalogue C-227

A. One-half gal. glass funnel. #6126

B. Glass tubing, combustion, pyrex, std. wall, 8 mm. outside diameter, #7206X, bent in U-shape with short leg 1", long leg 20" and diameter of bend 3"

C. Stop-cock, pyrex, straight bore of 2 mm. #12909

D. Glass tubing, capillary, pyrex, gauged accurately both ends, of size and length for particular installation #7203. (Purchaser should select from tabulation of hours of flow under different heads.)

O. Cylinder, graduated in 5 c.c., capacity 500 c.c. #3659KA

P, Q, S, T, U, V & W. Same as indicated for SKM-1

From Most Convenient Source

Y. Ten gal. crock

Z. Chlorine resisting hose, medium wall, $\frac{1}{4}$ " inside diameter

NOTE: There should be purchased at the outset an extra or spare of all glass and earthenware parts, four to six pieces of capillary tubing of the size and length needed, and the proper length of hose "Z" to reach the point of application.

ASSEMBLY AND OPERATION

The glass tubing extending from the stop-cock should be cut off at a distance of 2" from the center of the stop-cock. Where a regular gauge glass cutter is not available the cutting may be done by filing a slight groove entirely around the tube with a triangular file and then bending it at this point. Withdraw the core of the stop-cock and with a toothpick, wire or the like, remove any vaseline in the holes. If the vaseline on the ground surfaces of the core or socket does not appear to be fresh, remove it and apply fresh vaseline. The core should be cleaned and resurfaced with fresh vaseline periodically, once a week or once a month. If the core becomes "frozen" (stuck) release it by immersing in warm water for a short period of time. Tube "P," when filled with vinegar, is intended for use in soaking the capillary tubes to remove any calcium deposit. Vinegar may also be used to clean other parts of the feeders.

In the case of SKM-1, 5 c.c. graduations may be established on the funnel "B" by shellac and lines of paint, or by strips of tape at the points determined by measuring accurately the different quantities of water in cylinder "O" and then pouring it into the funnel. One c.c. equals 1 ml. Insert the glassware into rubber stopper "G" by wetting both the tube and the hole

with water. Push the tube into the stopper on a straight line, or turn the tube clockwise and counter-clockwise only slightly and easily if found necessary. In the event of gravity feed, the syphon is started by holding a finger over the outlet of tee tube "J" and compressing the air with bulb "K."

In the case of SKM-2, syphon tube "B" is held in place by attaching a cleat or wrapping friction tape about the tube at the proper point so as to suspend it correctly. The weight of the delivery line "Z" should be carried by a cleat or friction tape on the shelf and not on the syphon tube "B." For gravity flow the syphon is started by filling the delivery hose from the stopcock to the point where the hose is attached to tube "B."

The hypochlorite feeders must be operated on the basis of an orthotoluidine color test at the beginning of each day's operation. New color standards should be purchased every 6 months.

THE ORTHOTOLUIDINE COLOR TEST

1. Fill two test tubes "V" to the mark with the water to be tested.
2. Draw from bottle W into pipette "Q" a sufficient quantity of orthotoluidine nearly to fill the pipette. Lower the orthotoluidine in the pipette to the zero mark, returning all surplus orthotoluidine to the bottle as it is expensive. Introduce 0.5 c.c. of the orthotoluidine into one of the test tubes containing the water.
3. Mix the orthotoluidine and the sample of water by placing the thumb over the test tube and inverting it several times. Allow to stand for 2 minutes.
4. Place the orthotoluidine treated sample in front of the distilled water sample "S" and the untreated sample in the rear of the color standard "T" or "U." Hold them opposite good light and observe the color by looking through them from the side.
5. The chlorine dosage is determined by making the test immediately after the chlorine is introduced and the chlorine residual 15 minutes after the chlorine is introduced. The latter should always be at least 0.2 p.p.m. The amount of chlorine needed to

produce this residual at the end of 15 minutes is dependent upon the chlorine absorbing matter in the water. With waters relatively free of such matter a dose of 0.5 p.p.m. will produce a 0.2 p.p.m. residual, whereas waters high in such matter may require 0.8, 1.0, or a higher dosage in p.p.m. Where dechlorination is being effected with activated carbon a dose of not less than 1 p.p.m. should be applied or rather a residual of at least 0.5 p.p.m. just before contact with the carbon should be produced.

COST OF HYPOCHLORITE FEEDER

In August, 1933, the cost of single units with duplicate glassware (except the orthotoluidine set), 6 capillary tubes, 12' of black gum rubber hose and 12' of red chlorine resisting hose was, as follows: SKM-1, \$33.44; SKM-2, \$19.86.

HOURS OF FLOW

FIVE GALLONS OF LAKE MICHIGAN WATER THROUGH CERTAIN LENGTHS OF CERTAIN SIZES OF CAPILLARY TUBING UNDER DIFFERENT HEADS

| Head | Size of Tubing in Feet | in Milli- meters | Length of Capillary Tubing | | | | | |

INDUSTRIAL HYGIENE

Dr. J. A. Orenstein Honored—

At the sixth annual scientific meeting of the Medical Association of South Africa (British Medical Association) which was held in the University Buildings, Groote Schur, from September 25 to 30, the Association's gold medal for meritorious services was presented to Dr. J. A. Orenstein. (Our readers will be interested to know that Dr. Orenstein is a Charter Fellow of our section on Industrial Hygiene, having joined when he was with Dr. William C. Gorgas in the Panama Canal Zone, nearly 20 years ago.)—*Science* 2017:165 (Aug. 25), 1933. E. R. H.

Incidence of Illness Among Male Industrial Employees in 1932 as Compared with Earlier Years—

In a study of 40 industrial establishment sick benefit funds for 1932, as a whole the frequency of cases of disabling sickness lasting 8 days or longer, among a sample group of male industrial employees, differed little from the incidence recorded for the preceding year. In each of the past 3 years, in fact, the sickness rates for this group have exhibited remarkable stability at a lower incidence level than during the 1927-1929 period.

For certain causes of disability, however, greater changes in frequency may be noted. The respiratory disease rate was higher in 1932 than in either of the 2 immediately preceding years, due chiefly to an unusual prevalence of influenza in March and again in December, 1932.

Although the influenza rate was higher in 1932 than in 1931, there was no increase in pneumonia.

As has been pointed out in previous

communications, these sickness rates are based on the reports of a group of about 40 industrial establishment sick benefit funds, and apply in the main to employed men, although many work only on a part-time basis. For information concerning the health of the unemployed, other data obviously are required.—Dean K. Brundage, *Pub. Health Rep.* 48, 30:869-871 (July 28), 1933. E. R. H.

Correspondence Committee on Industrial Hygiene—Some fifteen members of the Correspondence Committee on Industrial Hygiene met at the International Labour Office July 3 to 5, 1933.

The meeting examined the draft of the forthcoming *Grey Report* relating to the extension of the list of occupational diseases contained in a Schedule to the International Convention on this subject, with special reference to the conclusions of the report relating to silicosis. After some discussion these conclusions were formulated in accordance with the views of the experts.

The meeting also drew up a formula for certain forms of poisoning to be added to the list of diseases giving rise to compensation; these included the halogen derivatives of the fatty series. In the course of the discussion on silicosis the meeting decided on the proposal of Dr. Bridge, to recommend that a study be made of the possibility of including fibrosis due to asbestos dust in the list of occupational diseases giving rise to compensation.

The meeting examined various questions of industrial hygiene which it decided to place on the agenda of the next meeting. These included medical in-

spection of factories, medical supervision in the factory, the study of work of a light, medium, and heavy character, the nutrition of workers, an inquiry into the health of hat makers, etc.—*Indust. & Lab. Inf.* 47, 3:119 (July 17), 1933.

E. R. H.

Health Hazard from Dust in the Mines and Allied Industries of the United States—Initial Survey of the Extent and Severity—A brief historical review is followed by a listing of the various public and private agencies, and their duties, in regard to the subject of the title. Dissemination of information is not only from these agencies but from the technical press, the International Labour Office, and manufacturing concerns. The present day makes an interesting comparison with the beginnings of a movement 25 years old.

The extent and severity of dust diseases is shown with tables, in connection with metal mining (including mills), coal mining (including washing), smelting and refining (non-ferrous), smelting (ferrous) and the manufacture of cement.

While no grand totaling is given of the numbers of workmen exposed to the dust hazard in the various industries, the separate totals are sufficient to indicate the wide extent of this kind of hazard.

There is no reason to think that human ingenuity and care will not develop methods of prevention or removal, even as it has done in aerial and gas warfare.

It seems a fair guess that, as metals and minerals become scarcer, the comminution of lower grade ores and rocks, largely siliceous, will increase the quantity of dust produced, since about 60 per cent of the earth's crust is composed of silica. It is evident that humanity has been exposed in some degree to the dust hazard for some little time, and

that it probably has developed a certain constitutional immunity through the ages that will carry it past this hazard. The paper is intended for discussion.—M. Van Siclen, Amer. Inst. of Min. and Metal Eng. (29 West 39th Street), New York, N. Y., *Contribution No. 45*, Aug., 1933, 13 pp.

E. R. H.

The Size Frequency of Industrial Dusts—Author's summary:

The results of measurements of 18,000 outdoor dust particles showed that nearly all of these are less than 1 micron in average diameter. The median size was found to be 0.5 μ . In contrast with this result it was found that only 21 per cent of about 6,000 industrial dust particles were less than 1 μ in size, the majority (69 per cent) being between 1 and 3 μ . The median size of the industrial dust particles was found to be 1.5 μ . These results clearly indicate that in conducting industrial dust studies our concern should be only for those particles ranging in size from 0.5 to 5 μ .

The instrument used in sampling industrial dust in air, the standard impinger apparatus, is shown to be capable of collecting, with a high degree of efficiency, dust particles of the sizes found in this study. The standard method used in enumerating dust particles is shown to take into account about 85 per cent of the dust present in industrial atmospheres. In addition, our studies have shown that a high correlation exists between dust counts obtained with our technic and the degree of silicosis and tuberculosis found in a study of health of granite cutters. The present study clearly indicates that the method used in enumerating dust particles collected by the impinger apparatus constitutes a valuable and practical index of the hazardousness of dust inhalation.—J. J. Bloomfield, *Pub. Health Rep.* 48, 32:961-968 (Aug. 11), 1933.

E. R. H.

Some Common Industrial Health Hazards—An occupational disease is an affliction which is the result of exposure to an industrial health hazard, while an industrial health hazard is any condition or manner of work that is unnatural to the physiology of the human being so engaged.

Author's summary follows:

1. It requires industrial health hazards to produce occupational diseases. Therefore, data on occupational diseases help to define such health hazards.

2. Standardization of reporting forms is advised as well as laws requiring the reporting of occupational diseases, irrespective of compensability.

3. It is considered that among the commonest industrial hazards are the following, which are discussed in some instances with statistics:

(1) The poisons—particularly lead, volatile solvents, and irritants including corrosives.

(2) Fatigue—which even in a period of depression is still a matter of unrestricted hours, night work, child labor, female labor, and a consideration of strain of bodily parts, particularly noticeable as tenosynovitis.

(3) Dust—which at present involves chiefly silica and silicates used extensively in various industries and requires common sense methods of control before refinements in certain particulars.

(4) Air conditions—which hinge upon the subject of temperature, atmospheric cooling power, and effective radiation, the latter of which is stressed both because it is a rather new discovery in physiological relationships and because it is often of the greatest importance in comfort and efficiency.

Various precision instruments for determining air conditions were demonstrated (described in the discussion).—Emery R. Hayhurst, paper before International Assn. of Industrial Accident Boards & Commissions, Columbus meeting: *U. S. Labor Bull.* 577:190-205, 217-224 (Apr.), 1933.

E. R. H.

The Silica Content of Lungs—The author refers first to the chemical analysis of post-mortem lungs from coal miners and associated workers, 35

all total, in South Wales, which he published in collaboration with Professor Lyle Cummins in 1930 in the *Journal of Pathology & Bacteriology* (33: 1095).

The present report consists of the analysis of 60 cases which are divided into 6 groups, depending upon the percentage of silica found in the dried lung substance. These percentages ran from less than 0.3 per cent to a total silica exceeding 2.4 per cent of dried lung substance. The author points out that of all dusts to which industrial workers may be exposed, "coal dust" in the mines is the most concentrated. This coal dust contains 0.6 per cent or more of siliceous matter which might amount to 50 particles of the same per c.c.

The Australian and South African workers have agreed that the "danger limit" for the purer forms of silica is 200 particles per c.c. Thus it would appear quite possible for a coal miner to inhale as much as 2 mg. of actual silica during a day's work. Working 250 days a year, 0.5 gm. of silica might reach the lungs in a year and in 10 years as much as 5.0 gm. could be inhaled.

In a study of the lungs of 24 coal miners whose deaths were due to accident or illness and not especially to lung fibrosis, analysis showed an average of 4.1 gm. total silica in the lungs of each man (1.15 per cent of the dried lung). Their total time of exposure to mine dust varied from 20 to 50 years. Thus an important proportion of silica inhaled must have been disposed of by drainage, or excreted. Nevertheless, an ordinary coal miner may acquire progressive damage to the lymphatic drainage so that after age 50, a damage to the lungs from the silica fraction may assume serious proportions. Experience among the Welsh coal miners certainly indicates 50 to 53 years as the "critical age" in this respect.

Coal dust alone, apart from silica,

cannot be regarded as a cause of serious fibrosis of lungs, and such minimal fibrosis as does occur in this class of worker can be explained as due to the action of traces of siliceous dust present even in high-grade "pure" coal.

Collins and Gilchrist (*J. Indust. Hyg.* 1928:101) have shown that coal miners have an excessive mortality rate from pneumonia and bronchitis.

The conclusion is that when the silica content of the lungs exceeds 1 per cent of the dried lung substance, the resulting fibrosis clearly contributes toward death. When the silica content exceeds 1.6 per cent the associated fibrosis is sufficient in itself to lead to death.—A. F. Sladen, *Lancet*, 5733:123-125 (July 15), 1933. E. R. H.

Review of Silicosis—The author's article appears serially in the *New York Industrial Bulletin* in February, April, June, and July, 1933. Subjects of discussion are: Part I, Definition of silicosis; chemical properties of silica; Part II, Exposure to silica dust in industry; factors in the development of silicosis; silicosis abroad; silicosis in the United States (by industries); summary of hazardous industries; silicosis in New York State; Part III, Symptoms and course of silicosis; physical signs, complications of silicosis, X-ray appearances. — Adelaide R. Smith, *Indust. Bull.*, Dept. of Labor, 12, 32-33, 90-92, 144-146, 176-178, 1933. E. R. H.

Court Decisions—Bronchitis, aggravated by exposure to inhalation of gas and smoke to result in steady coughing, is an occupational injury compensable under the Massachusetts law.—Massachusetts Supreme Judicial Court.

A man employed on construction work died from sunstroke while working overtime in the sun on a hot day. Compensation to the widow was denied;

but, upon appeal, the ruling was reversed and compensation awarded on the ground that the workman was exposed to a far different hazard than the public generally.—New Jersey Court of Errors and Appeals.

An employee was in a camp at a training school for salesmen. One night a severe storm blew down his tent and he was drenched and caught a cold which developed into acute arthritis, necessitating hospitalization. Compensation was denied; but upon appeal the decision was reversed and the case was remanded with directions to award compensation.—New York Appellate Division.—*Bull. Assn. of Cas. & Sur. Ex.*, 34:20, 22 (July), 1933. E. R. H.

Compensation for Silicosis—Data published in the "Sixth Annual Report of the Workmen's Compensation Commission of New South Wales" (pp. 53-57) indicate that the cost and expense of compensating for silicosis, in special occupations in the County of Cumberland, under "Workmen's Compensation (Silicosis) Scheme 1," from September, 1927, to April, 1932, have averaged about 6 per cent of wages.—*Bull. Assn. of Cas. & Sur. Ex.* 34:13 (July), 1933. E. R. H.

Bite by Infected Wood Tick Held Compensable—A traveling salesman employed by The Boise Grocery Company traveled through a tick infested area doing his regular duties. While extricating his car from a mud hole, a wood tick embedded itself in his right leg (March 27, 1932). On March 31 he also found a tick bite on his left shoulder. He was taken sick a few days later, entered a hospital in Boise on April 5 and died of Rocky Mountain spotted fever 11 days later.

The Supreme Court of Idaho upheld the Industrial Accident Board in making an award to the widow with the

statement that the highways he traveled, the hotels he stopped at, and the stores he visited became and were his workshop; they were the places where he constantly spent his time and worked for his employer. . . . Consequently, the deceased was exposed to the danger of being bitten by an infected wood tick in a greater degree than those who lived in the wood tick territory and traveled over the highways traversing it.—*Month. Labor Rev.* 37, 2:314 (Aug.), 1933. E. R. H.

Workmen's Compensation Act Held Not to Take Away Right of Action for Noncompensable Disease Caused by Employer's Negligence—The West Virginia Supreme Court of Appeals in the *Jones v. Rinehart & Dennis Co., Inc.* (168 S. E. 482), decided it seemed clear that an employee had a right of action at common law for diseases arising out of his employment through the negligence of his employer, and that, if such right of action had not been taken away by the compensation act, the administratrix of the decedent in the instant case had the right to prosecute the action under the statute relating to death from a wrongful or negligent act.

Recurring to the query as to whether the above quoted statutory provision exempted an employer, who was protected by the compensation act, from liability for a wrong to an employee arising from a disease contracted in the course of his employment through the negligence of his employer, even though the disease was not compensable under the compensation statute, the court said that it was "difficult to perceive a satisfactory and reasonable basis for exemption of employers from liability for disease caused by their negligence, such disease being noncompensable under the compensation statute," and declared that "we are of opinion that it was the legislative intent, as expressed in our

compensation law (Code 1931, 23-2-6, Code 1932, sec. 2516), to exempt employers from liability for damages at common law or by statute for compensable injury or death of employees, however occurring, but not to exempt from liability for noncompensable disease (caused by negligence of the employer) or death resulting from such disease."—*Pub. Health Rep.* 48, 26: 764-766 (June 30), 1933.

E. R. H.

Occupational Dermatitis and Compensation—The author gives tables to show dermatitis classified according to decision of referee, to length of disability and disposition of cases, to parts affected and disposition of cases, to causative agent and disposition of cases—the whole with accompanying discussion.

In all, 520 claims for occupational dermatitis were heard during the 18-month period covered in the report. Of these, 240 or 46 per cent were disallowed, and 182 or 35 per cent received awards. More than half of the disallowed cases were so disposed of because the disability did not exceed 7 days, or the claimant failed to appear, or the disease was not contracted in the course of employment, or for similar reasons. Since the law does not give complete coverage for all forms of industrial dermatitis, the only remedy is to change the law to cover "any disease proved to be due to the claimant's employment."—Freda S. Miller, *New York Indust. Bull.* 12, 3-4: 60-61, 84, 88-89, 94 (Mar. and Apr.), 1933.

E. R. H.

What Determines Compensability for Skin Diseases Among Industrial Workers?—Discussion is given at length concerning the differential diagnosis of occupational dermatoses, the function of patch tests, the importance of history of previous skin affections,

sensitization and allergy, complications of industrial dermatitis with relation to industrial compensation, and a suggestive course of action for compensation bodies.

The latter subject of discussion (course of action) is of particular interest as a guide for compensation purposes and should be read in the original. In connection with his paper Dr. McCord demonstrated, with the assistance of Mr. Wiley, some examples of patch tests. A valuable discussion follows.—Dr. Carey P. McCord, paper before Internatl. Assn. of Industrial Accident Boards & Commissions, Columbus meeting. *U. S. Labor Bull.* 577:205-217, 217-224 (Apr.), 1933.

E. R. H.

Compensation for Occupational Diseases in Denmark—The Danish Act of May 20, 1933, relating to compensation for industrial accidents, which will come into force on October 1, 1933, provides also for compensation for a number of occupational diseases.

These include, in addition to those covered by the Convention on this subject adopted by the International Labour Conference in 1925 (lead poisoning, mercury poisoning and anthrax), chronic and recurrent skin diseases due to exotic woods, and lung diseases due to inhalation of dust from stone and ores in eight specified industries. The Act does not cover skin diseases caused by certain products which were included in the original Bill.—*Indust. & Labour. Inf.*, 47, 1:41 (July), 1933.

E. R. H.

A Modern Plan for a Community Campaign Against Air Pollution—The author considers air, water, and food purity equally important. The discussion concerns smoke regulation, a survey of atmospheric pollution—soot-fall, air-borne solids, sulphur dioxide,

natural sunshine, other meteorologic data, and an inquiry concerning the causes of pollution, with a brief word on legislation and economic applications.

City dwellers have a right, as a matter of public health, to expect the standard of air purity will be brought up to a parity with that already fixed for water and food; that the rôle of leadership in this movement belongs to the medical profession; that current conditions are unusually favorable for campaign success; that a workable plan of campaign would help immediately to reduce unemployment, spur scientific research, aid infant industries and assist in the restoration of real estate values.

"In conclusion, be assured that in connection with whatever action you may take you are free to call upon Mellon Institute of Industrial Research for any assistance it may be able to give, in the light of its 20 years of scientific investigation of the problems of air pollution."—H. B. Meller, *Am. J. Med. Sc.* 737:157-165 (Aug.), 1933.

E. R. H.

Temperature Gradient Observations in a Large Heated Space—The authors investigated the temperatures at various levels in the field house at the University of Wisconsin. The description of the heating and ventilating system is given. Excerpts from the conclusions follow:

Under gravity circulation and near zero outside temperature conditions, a temperature gradient of about $\frac{3}{4}^{\circ}$ per foot was found for the first 15 ft. of elevation and about $\frac{1}{10}^{\circ}$ per foot from 15 ft. to 97 ft. at the peak of the roof.

A fan system is considered desirable in this type of building in order to reduce humidity by the introduction of outside air and at times to remove the heat from the audience.

It is considered safe and desirable in

this type of a building that the designer use the temperature gradient observed under gravity circulation rather than any found with fan recirculation.—G. L. Larson, D. W. Nelson, and O. C. Cromer, *Heating, Piping and Air Conditioning*, Sept., 1933, pp. 477-485.

E. R. H.

Zinc in Relation to General and Industrial Hygiene—Authors' summary:

1. In 1925, a publication of the Public Health Service (*Reprint 1029*) placed a limit of 5 p.p.m. of zinc in drinking water. This limit has been applied freely to many conditions in which zinc is ingested. Since the zinc is not of itself poisonous, and many times 5 p.p.m. may be taken without harmful effects, it is suggested that this limit, which gives a relatively innocuous metal an undeserved reputation for toxicity, be increased or done away with altogether.

2. Foods or beverages, with the exception of simple or chlorinated drinking water, should not be stored in zinc-lined or galvanized containers. Acid drinks and foods will invariably cause solution of zinc and the formation of simple compounds of zinc which irritate the stomach and may cause vomiting.

3. A single industrial condition arises from zinc and this condition is not produced by zinc alone. This is the "zinc chill," better known as metal fume fever. The different groups of symptoms described as chronic industrial zinc poisoning, together with other complex ills which have been ascribed to zinc, may be disregarded, as they are due to contamination by other substances.—Cecil K. Drinker and Lawrence T. Fairhall, *Pub. Health Rep.* 48, 32:955-961 (Aug. 11), 1933. E. R. H.

Lead Absorption and Compensation—The author distinguishes between lead absorption and lead poisoning. In an examination of 381 lead workers, 149 presenting a clinical picture suggestive of lead absorption and laboratory tests confirmed the diagnosis in approxi-

mately two-thirds of these. In the remaining one-third, it was considered that the symptom-complexes present were probably due to other causes. None of these workers were incapacitated. In lead absorption workers may be apparently healthy and have no complaints. Hence they present no problem because there is no disability but they demand general prophylaxis and prevention of acute lead poisoning.

Compensation cases are those where disability is actual or claimed. In acute cases the diagnosis can usually be made with a sufficient degree of certainty. In the subacute cases the difficulties of diagnosis on the basis of the clinical picture alone are obviously very great. Thus constipation, severe headache, or abdominal pain may or may not be due to lead poisoning. The probability that lead exposure is a cause would appear to be approximately (from the above) two to one. Here careful laboratory tests are valuable and compensation may be justified. The worker very properly should be given the benefit of what slight doubt exists.

For several years the New York State Division of Industrial Hygiene has offered to make the necessary tests for physicians at cost, but for some reason physicians have not availed themselves of this offer. About two-thirds of the troublesome cases could probably be disposed of, from a compensation point of view, if the physicians would prepare their cases fully, including the necessary laboratory tests of blood and urine.—May R. Mayers, *Indust. Bull.*, New York Dept. of Labor, 12, 2:33-34 (Feb.), 1933.

FOOD AND NUTRITION

Microbiology of Frozen Foods.
VI. The Survival of Pathogenic Microorganisms in Ice Cream—Numerous studies have been made on the longevity of pathogenic microorganisms in dairy products with the exception of ice cream. This product has no doubt been neglected because freezing was thought to be destructive to microorganisms. However, numerous epidemics of disease have been traced to ice cream. Since tuberculosis is the most important disease transmitted by dairy products the longevity of these organisms in ice cream was studied. Two members of the salmonella group were also studied. The following organisms were used: *S. aertrycke*, *S. enteritidis*, *Br. abortus* Bang, *Br. abortus* porcine, *Br. melitensis*, *Mycobacterium tuberculosis* hominis (Strains A, I and S), *Mycobacterium tuberculosis* bovis and *Mycobacterium tuberculosis* avium.

Guinea pigs were injected with 1 c.c. amounts of the ice cream samples containing the *Brucella* and tubercle organisms. All animals remaining alive after 2 months were necropsied. The animals inoculated with the ice cream tubercle bacilli were examined, at the time of death, for characteristic lesions of the spleen and liver and at the point of injection. The paratyphoid and undulant fever organisms were frozen in the ice cream for a period of 36 months and in all cases the organisms were still viable and present in sufficient numbers to be rather easily detected. The different strains of the tubercle bacilli were still viable and potent after 30 months. All produced characteristic lesions in guinea pigs in a comparatively short time.

While the artificially inoculated ice cream contained more organisms than would be encountered in ice cream made from naturally infected raw milk, such data suggest that ice cream should not be considered as a safe food just because it is frozen.—G. I. Wallace and Rhoda Crouch, *J. Dairy Sci.* 16:315 (July), 1933.

The Vitamin B and G Content of Wheat Germ, Rice Polishings, Cottonseed Flour and the Residue from Fermented Rye Flour—Rats, 28 to 29 days old, were used as experimental animals. In testing for vitamin B, a basal diet of purified casein, Osborne and Mendel salt mixture, starch, butterfat, cod liver oil and yeast was fed. In testing for vitamin G, a basal diet of purified casein, Osborne and Mendel salt mixture, butterfat, cod liver oil and the extract from 90 gm. of white corn plus cornstarch to make 100 per cent was fed.

In both cases, at the end of the 2-week depletion period the material to be tested was fed. At the end of the 8-week test period, the rats were killed and autopsied.

The samples of wheat germ, cottonseed flour, and rice polishings were found to be excellent sources of vitamin B. All three substances contained approximately one-half as much of the anti-neuritic factor as did a composite sample of dried yeast. As a source of vitamin G they differed widely. Wheat germ was found to be the richest of the three substances, containing about one-sixth as much vitamin G as did the yeast. Cottonseed flour was found to have about one-tenth as much of this vitamin as yeast, while rice polishings

had only about one-twentieth. Whole wheat (soft winter) was found to be a relatively poor source of both vitamins B and G. The flour made from the residue from fermented rye grain contained a very small but appreciable amount of vitamin B.—Hazel E. Munsell and Grace M. Devaney, *Cereal Chemistry*, 10:287 (July), 1933.

Vitamin C Content of Baldwin Apples and Apple Products—Since Nelson and Mottern in 1932 (*A.J.P.H.* 22, 6:587–600, June, 1932), reported that lead arsenate sprays applied to orange trees considerably reduced the vitamin C content of the fruit, and since apples are almost universally sprayed with arsenic compounds and other toxic substances, the present investigations were undertaken to compare sprayed and unsprayed Baldwin apples grown in Massachusetts. Lime-sulphur and lead arsenate were used and the usual spray schedule was followed.

Guinea pigs were fed, in proportion to their weight, a basal ration of rolled oats and wheat bran, vitamin C-free baked milk powder, butterfat, cod liver oil, and salt. All vitamin C was derived from the apples. The sprayed apples were found to be fully as rich in vitamin C as the unsprayed apples. Four gm. daily of either sprayed or unsprayed Baldwin apples per 300-gm. guinea pig, gave excellent weight gains and full protection from scurvy. In 2 of 3 tests the sprayed fruit appeared to contain slightly more vitamin C than the unsprayed.

Tests were also made to determine the effect of storage on vitamin C. In 4 to 6 months of storage, at 36° F., Baldwin apples lost about 20 per cent of their vitamin C content; in 8 to 10 months the loss was nearly 40 per cent.

Freshly expressed Baldwin apple juice was found to be nearly as rich in vitamin C as the fresh apples. Little

loss occurred during the first 24 hours after extraction. However, benzoated or pasteurized ciders, over 48 hours old, failed to retain an appreciable quantity of vitamin C.

Canned Baldwin apple sauce, either strained or unstrained, proved to be a poor source of vitamin C, the unstrained being somewhat superior to the strained.—C. R. Fellers, M. M. Cleveland, and J. A. Clague, *J. Agri. Res.* 46:1039 (June 1), 1933.

The Iodine Content of Hens' Eggs as Affected by the Ration—The common use of eggs in the human dietary, especially for infants and invalids, and the rather extensive use of iodine in the treatment of endemic goiter, make it desirable to have further information on the extent to which the iodine content of eggs is affected by the iodine intake of the bird.

Eighteen White Leghorn pullets were divided into 3 lots of 6 birds each. In addition to the basal ration, lot 1 received dried kelp, lot 2 iodized linseed meal, and lot 3 potassium iodide evaporated on dextrin. These products were fed in gelatin capsules in such amounts that each bird received 2 mg. of iodine daily.

After 4 weeks, the kelp feeding in lot 1 was discontinued, and the amount of iodine in the form of iodized linseed meal and potassium iodide was increased to 5 mg. daily, in the case of lots 2 and 3. The feeding of 2 mg. of iodine daily, either as kelp, iodized linseed meal, or potassium iodide, increased the iodine content of the egg approximately 75 times. When the level of iodized linseed meal and potassium iodide was increased to 5 mg. of iodine daily, the iodine percentage of the egg was increased about 150 times.

The amount of iodine in eggs is independent of the form in which it is fed to the bird, and the percentage of iodine

in eggs immediately decreases upon the discontinuance of iodine feeding.

The authors express the opinion that whether eggs of a known iodine content have a particular place in human nutrition depends upon whether the iodine requirements of the people of a given locality are provided from other sources. It is common knowledge that the natural foods and drinking water of certain sections are deficient in iodine, and that some form of medication must be resorted to in order to prevent and control endemic goiter, but how this can be best accomplished is an open question.—O. H. M. Wilder, R. M. Bethke, and R. P. Record, *J. Nutrition* 6:407 (July), 1933.

Specificity of Hexuronic (Ascorbic) Acid as Antiscorbutic Factor—After presenting a review of the literature both favoring and opposing the thesis that hexuronic (ascorbic) acid is itself vitamin C the authors describe certain experiments to ascertain whether antiscorbutic activity is an inherent property of hexuronic acid itself or due to some associated impurity. It was shown that the antiscorbutic activities of several natural sources of hexuronic acid, as, for example, ox suprarenal gland, were approximately proportional to the amounts of hexuronic acid recoverable from them. By biological assay specimens of hexuronic acid from different sources, such as suprarenal gland and paprika, were found to have identical antiscorbutic activity.

Tests of specimens of hexuronic acid of varying degrees of purity demonstrated that a given amount of hexuronic acid always had the same activity irrespective of the presence of impurities. Hexuronic acid after purification and recrystallization always maintained its original activity.

A large variety of foodstuffs covering

the widest possible range of biological activities were tested chemically for their hexuronic acid content. By experiment it was then found that the vitamin C value calculated from the known hexuronic acid content in all cases agreed with the value as determined biologically. The hexuronic acid content of lemon juice, orange juice and grapefruit juice was estimated by the intensity of ultra-violet absorption and the values obtained were in good accord with titration results and biological determinations.

With the knowledge that the suprarenals of normal guinea pigs had intense antiscorbutic activity and that this activity disappeared with the development of scurvy, experiments were conducted to demonstrate that the loss of antiscorbutic activity in the suprarenals ran parallel with the disappearance of hexuronic acid. A similar phenomenon occurred in the liver of the guinea pig.

Chemical tests on the suprarenals and livers of rats and dogs which are able to synthesize their own vitamin C when none is provided in the diet showed that the maintenance of vitamin C activity was associated with the presence of hexuronic acid. The authors further report that the conditions of aeration, heat and alkali which favor the destruction of hexuronic acid are the same as those which are known to determine the destruction of vitamin C activity.

Experiments with germinating seeds showed that hexuronic acid is synthesized concurrently with vitamin C activity by the plant on germination.

The authors conclude that hexuronic acid is itself vitamin C and they recommend the adoption of a specimen of hexuronic acid as an international standard of vitamin C activity.—Leslie Julius Harris and Surendra Nath Ray, *Biochem. J.* 27:580, 1933.

CHILD HYGIENE

Effects of Unemployment on Children and Young People in Belgium—*Report based upon findings of the Oeuvre Nationale de l'Enfance, Brussels. Richard A. Bolt, M.D., Dr.P.H., Oberlaender Award, Berlin, Germany.*

THIS report gives a very good idea of the number of young persons unemployed in Belgium, the effects of such unemployment, and the measures which have thus far been taken to prevent serious breakdown among the child population. In addition to the public health and social measures already applied, two new organizations were created to assist the unemployed. They were the General Relief Committee for Brussels and environs and the Central Assistance and Loan Committee for out-of-work employees.

Unemployment in Belgium is of too recent date, it seems to us, to allow of a serious study being made of its effects on children. On the other hand, the organizations created or subsidized by the Oeuvre Nationale de l'Enfance, the local or regional institutions and the private organizations are so numerous, and their work is so systematically planned, that one may hope to be able to prevent, or to palliate the effects that the unemployment of the parents may have on the physical and mental development and the moral and social attitude of the children.

Infants—From inquiries made among child welfare organizations, and from answers given by doctors and nurses, it would appear that, on the whole, the baby lacks for nothing—the baby is well cared for, because the parents are intelligent enough to make sacrifices for it. Child welfare propaganda has taught the parents how to keep their little ones in good health and to give them what they need, even at the price of personal discomfort.

This must not lead us to conclude that in Belgium no infant suffers through the weakness of the nursing mother or through the impossibility of giving it a prescribed diet.

This is often the case, particularly among families already in straitened circumstances before the economic crisis and that the crisis has reduced to dire poverty.

The Oeuvre Nationale de l'Enfance notes a steady increase in the number of children cared for by its Child Welfare Centers and its Home Visiting Service. The figures have increased from 61,441 in 1929 to 78,064 in 1931. It would be a serious mistake, however, to attribute this rise to parental unemployment—at least, up to the present time; it is the result rather of child welfare propaganda. Indeed, it is legitimate to hope that the extension taken by child welfare work will permit of forestalling the effects of unemployment on the child.

Children of Preschool Age—These children, from 2 to 5 years old, include two categories: those who attend nursery schools, and those who do not. The latter, even in normal times, are not touched by the organizations; they are the "little unknown," who are no longer babies because "they eat everything," who have to be pleased with what is given them, and who have no means of voicing their troubles. The following observation, made in one of our big provincial institutions, throws light on the situation on these "in-betweens":

"They are brought to us in the belief that they are ill; they are only badly fed. It is sad to hear them crying, because, after all, we must let them go back to their families. And the parents again give them the same food as the older children, which is not suited to them at all. There is no compensation in the sacrifice of the parents, who give them a copper or two to buy sweets to make up for an unsuitable meal."

Children of School Age—Among older children the situation is less serious. There are, of course, many who lack supplementary food (weakly children) or the substantial nourishment (children of a large family) they are in need of, but such cases are known and supervised. They are given meals by the school organizations, who are doing really excellent work. School kitchens function in most important centers, but it is none the less true that the weakly and the undernourished must be sought out. Such children exist, not only as in the past among the population customarily dealt with by the Oeuvre Nationale de l'Enfance, but also among

families that never thought they would one day be forced to appeal to a charitable organization and that only resign themselves to do so when they are at the last gasp.

The children of school age benefit by school holiday camps, both at the seaside and in the country. In 1931 the Oeuvre Nationale de l'Enfance received into such institutions 6,592 children, totalling 514,476 days' maintenance. In 1932 the Oeuvre Nationale de l'Enfance paid particular attention to applications made by out-of-work families. Out of a total of 9,884 children admitted into its various institutions (up to October 1), 1,057 were children of the unemployed, chiefly from Brussels and the provinces of Hainaut and Liege.

Special measures against unemployment have been suggested and some of them have been put into operation. The following are the most important:

The Socialist Workers' Central Council has suggested the opening in every library of a special reading-room, the arrangement of debates, study groups, courses of lectures, walking or cycling tours, visits to industrial, social and educational institutions, as well as local study weeks or fortnights. The Trade Union Federation of Charleroi has established additional training classes.

M. Renard, Permanent Deputy of Brabant, suggested an extension of the school age or, at least, attendance at regular technical courses for pupils about to leave school. For apprentices proper, who are already on the dole, attendance would be compulsory and a return for cash received.

M. E. Veuchet, Inspector General of Technical Education, Province of Hainaut, proposed that the worker should be taught trades similar to his own, especially the small jobs of everyday life, the original trade remaining of course the main subject. The unemployed of overcrowded branches could be taught trades which are less popular.

M. Damoiseaux, Governor of Hainaut, and M. Pasteur proposed in addition to a policy of public works absorbing large numbers of unemployed, the extension of the school age to 16 for both boys and girls attending elementary, technical and domestic schools; and for young persons between 16 and 19, attendance at special technical courses.

In 1930, Mme. Plasky, Principal Inspector, Ministry of Justice, Labor and Social Welfare, suggested forbidding factory work for girls between 14 and 16, and introducing compulsory apprenticeship in sewing, dress-making or housekeeping.

These suggestions led to the drafting of two bills laid before Parliament by M. Masson in 1931. The first proposed that girls of 14 years should have 2 additional years of domestic economy; the second provided penalties for infractions of the law (to be voted) forbidding the employment of women and children, and also of their period of domestic training. Serious opposition, however, was raised on account of the alleged need for female labor in certain of the industries.

Unemployment seems to be more serious for the young men than for the young girls; for wherever the kind of work permits, the young girl is preferred, since she accepts a lower salary, does equally good work and is often quicker and more accurate than the young man.—

Children, Young People and Unemployment. Part I, Belgium, pp. 93-106. Published by The Save The Children International Union, 1933. 15 Rue Levrier, Geneva, Switzerland.

PUBLIC HEALTH NURSING*

Echoes from the I. C. N.—American nurses are still wending their way homeward from the International Congress of Nurses which began in Paris, July 7 and ended in Brussels, July 15.

Over 2,000 nurses from 42 countries registered at the Congress.

The seven new countries admitted to membership before an enthusiastic audience in the great Trocadero in Paris were: Austria, Czechoslovakia, Estonia, Iceland, Japan (including Korea), and Hungary.

Some special topics of discussion were:

Mental Hygiene—Experience in psychiatry and mental hygiene was recommended as part of the basic training of every nurse. Miss Taylor of Yale University advised that schools of nursing be discontinued in mental hospitals because most of the care required is of custodial nature. Training in general hospitals which have the stress of mental factors emphasized directs the attention of the nurse to the whole human being.

A delegate from Finland said that her country had improved the mental hygiene teaching of its nurses by insisting that the supervisors and superintendents in mental hospitals be properly prepared for their work by post-graduate courses.

The recommendation was made that the mental hygiene committee of the I. C. N. consider further the development of under- and post-graduate courses in mental hospitals and the development of post-graduate courses for teachers of mental hygiene.

Supply and Demand—It was brought out by an American nurse that satisfactory maintenance of community health would entail the employment of 53,000 public health nurses in the United States, when actually there are about 16,000 employed.

If student nurses in hospitals were replaced by graduate nurses, 70,000 of the latter would be needed to maintain good nursing service in these institutions.

Bulgaria and India reported a shortage of trained nurses.

Nurse Journalists—The Editor of the *British Journal of Nursing* reported a dearth of suitable women for posts open in journalism. It was brought out that the first requisite for journalism is "the ability to write clearly of things felt, heard, and imagined."

State Supervision of Nursing—The Grand Council recommended that state registration of nurses be instituted in all countries, that registration be made compulsory, and that nursing schools be adequately inspected. It was suggested also that good standards of nursing could not be upheld without the support of the medical profession.

Public Health Nursing (Emphasized at the Brussels Meetings)—A Canadian delegate urged that nursing education be interpreted in terms of *end results*. "Exact hours of theoretical instruction and exact hours of ward practice are not measures of education. Judgment must be based rather on qualitative results. Was the theory well integrated with practice to give the ideas color and meaning?"

A delegate from Brazil thought that all public health nursing should be administered through government bureaus,

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

as is done in her country, where it is acknowledged that public health nursing "should be an official service, like the public schools."

Miss Goff, the nurse representative on the Health Section of the League of Nations, speaking for Mary E. Gardner, read the following recommendations on public health: "(1) That an international clearing house be established at the I. C. N. headquarters; (2) that preparation for public health nursing be worked into the basic course; (3) that refresher courses be arranged for all public health nurses; (4) that nursing texts be revised to include preventive and social aspects."

New Officers: *President*, Miss Lloyd Still, Matron and Superintendent of Nurses at St. Thomas' Hospital, London (Great Britain); *First Vice-President*, Miss Clara D. Noyes (United States); *Second Vice-President*, Miss Bella Alexander (South Africa); *Treasurer*, Miss Ellen M. Musson (Great Britain); and *Secretary*, Miss Christiane Reimann (Denmark).

The next Congress will be held in London in 1937.—Paris—Brussels in Retrospect—*Trained Nurse & Hosp. Rev.* LXLI, 2:114, 117, 123, 125, 133, 134, 135, 139 (Aug.), 1933.

The Public Health Nurse and the Federal Government—Federal recognition of the need for standards in public health nursing is seen in an editorial preface to a reprint just issued by the Public Health Service of the United States Treasury Department.

The reprint is of "The Objectives in Public Health Nursing" and "Minimum Qualifications for Those Appointed to Positions in Public Health Nursing." The "objectives" and "minimum qualifications" were printed first in *Public Health Nursing* after their determination by committees of the National Organization for Public Health Nursing working in connection

with committees of the American Public Health Association. The editorial note follows:

Since public health nursing has assumed a definite and important place in modern public health programs, it would seem desirable that the objectives of public health nursing be outlined and the qualifications of the public health nurse be tentatively set as an approach to standardization. As of especial interest, therefore, to public health administrators and to those desiring to enlist their services in this specialized field of nursing, there are presented here two articles dealing with objectives and qualifications. These articles are published not with the suggestion of finality but rather as points of departure for future development based on experience and attainable ideals in the important field of public health work.—

N.O.P.H.N. News Release, Aug., 1933.

Two of Our Nursing Leaders Are Doing Their Bit—Sophie C. Nelson, President of the National Organization for Public Health Nursing, and Lillian D. Wald, President of the Henry Street Visiting Nurse Association and Honorary N.O.P.H.N. President, have just accepted appointments to serve with Mrs. Franklin D. Roosevelt and some fifty other leaders on the National Women's Committee for the 1933 Mobilization for Human Needs, the nation-wide welfare appeal. Miss Nelson is the only member of the Committee from Massachusetts.—N.O.P.H.N. News Release, Aug., 1933.

Good for New Mexico!

Budget hearings this year have been enlightening and a pleasure to attend. At a time when the common cry has been lower taxation—when worried county commissioners, school board members and city councilmen have faced the problem of balancing their county's or city's budget, the pioneer spirit of individual service and sacrifice for the common good, has prevailed.

In Otero county a rising vote of men and women, all of them taxpayers, who were attending the preliminary budget hearing, indicated that they preferred a full term of school and the services of a public health nurse to lower taxation by disproportionate

reduction in the program for the education and welfare of their children.

In one county the commissioners after reducing every item in the budget, reduced their own salaries 20 per cent—But—there was no thought of discontinuing the nursing service.

In another county, no appropriation was made for the nursing service when the preliminary budget was prepared. When the final hearing was held, advisory nursing committee members and other interested lay people, all of them taxpayers, demanded that an appropriation be made for the nursing service.

In still another county which does not support a nursing service, the city attorney, representing the county seat, offered \$400, office space, water and light, if a nursing service could be secured for that county.

At another hearing four superintendents of schools attended the health budget hearing and pledged their financial support to the service that they considered essential to the promotion of health and sanitation in their schools.

What is happening in New Mexico? Just

this—through the health education programs of the public health nurses our people are becoming public health minded. Health education in the schools, home visits, classes in home hygiene and care of the sick, and other phases of the excellent public health nursing programs being carried by the New Mexico nurses have brought the work of the nurses before the people. Advisory nursing committees deserve much credit. The members have attended meetings, advised and assisted the nurses, and last, but most important, they have interpreted the work to their neighbors. Publicity given to an adequately rendered public service will eventually cause a demand for more of this service. Here's to New Mexico's Public Health Nurses! To them go the credit and the glory for the demand for the nursing services at a time when they are most needed, when lack of funds causes county commissioners and taxpayers many a sleepless night.—

Elenor L. Kennedy—The Nurses Page—*New Mexico Health Officer* III, 3:7 (Aug.), 1933.

EDUCATION AND PUBLICITY*

Education and Publicity Headquarters—When you wish to find someone to talk to about health education and publicity at Indianapolis drop in at our Headquarters. We will be better situated than at Washington.

Hundreds of questions can be answered by the classified portfolios on display. There will always be fellow workers present ready to exchange ideas and experiences.

Surely People Are Making Wills—And bequests are being planned whatever may be the general economic situation. *Will your agency be among the elect?*

A good job of bequest seeking calls

for much careful preparation. As a first step could a board member or other volunteer, with or without the collaboration of a staff member, look into the matter and make recommendations as to the next steps?

A detailed outline of methods, with sources of information, is a 7-page memorandum, "Bequests and Trusts," issued by Social Work Publicity Council, 130 East 22d St., New York, N. Y. 6 cents; 2 or more copies, 5 cents each.

Have You a List for Indianapolis?—Expense accounts are likely to justify most for those who list in advance some questions to be answered, and some problems to be discussed. At least one question to be asked, one problem to be talked over, one idea to be passed on. will give point and purpose to one's

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

attendance at the A.P.H.A. October meeting in Indianapolis.

The Psychology of Health Education—This is the theme for the Health Education Institute, Indianapolis, Oct. 7-9, 1933:

Its application to mass education and its utilization in the written and spoken word and to the graphic media.

The faculty: Dr. Iago Galdston, Dr. H. E. Kleinschmidt, Bertrand Brown.

The outline:

- a. Why the psychology of health education?
- b. The psychologic nature of the recipient of health education.
- c. Fundamental principles relative to:
 1. Arresting attention
 2. Enlisting sympathy
 3. Imparting information
- d. Meaning and mechanism of motivation.
- e. Practical demonstrations; the application of the outline of psychologic principles to health education instruments; the spoken text, the printed text and graphic material.

Applications: to American Public Health Association, 450 7th Ave., New York, N. Y.

Too Many Ideas on the Air?—The pleader for public health is tempted to cover too much ground, to try to tell too many things, without telling enough on each point to make it clear to the diverse audiences reached by radio. Examples and other illustrations and comparisons will add interest as well as understanding. To state a situation as it will be met by a health department will mean more to the listener than the assertion that the health department will surely handle such a situation.

One idea, one argument, one illustration, any one point lodged in the minds of radio listeners means more for the local health department than any well rounded review of all that the department does and all the reasons for its maintenance.

Let's concentrate and clarify *and* convince.

Are Radio Talks Too Casually Presented?—The summer's output of broadcast appeals for maintenance of health department work show that we can get time on the air. The broadcasts do not show that we are willing to pay the price for holding the audience.

The subject, the sponsorship, the well known participants, each draw their share of audience. But it is up to the participants to hold and to convince that audience. Even a newspaper reader is probably less fickle than the radio listener.

Most of all do we need a bit of showmanship in our broadcasts. Whatever we say will interest and convince if well presented. Rehearsals before unafraid critics are almost essential to success. The individual broadcaster should become familiar with the *sound* of every word of his manuscript. Emphasis and tone of voice should be studied and marked on the manuscript.

Where two or more participate in a discussion, individual familiarity with the *sound* of the words should be followed by joint rehearsal. Here a good director of amateur theatricals could be brought in to advantage. He should be expected to be as hard-boiled as when holding a play rehearsal. He should be expected to see that our health talkers get their lines over to an invisible, but very real and very human audience.

Big names, prominent sponsorship, and importance of the topic will not put put over an unprepared presentation.

Is "Per Capita" Convincing?—A few weeks ago "50 cents per capita" was emphasized in a radio talk. Not long ago national "per capita" costs of some \$4 or \$5 each for fire and police protection were compared with the much smaller national "per capita" cost of public health services. Who is "per

capita"? What are counted? What is the relation of "per capita" to the individual tax-payer? *Are we clear? Are we convincing?*

Comparing national "per capita" costs for public services has little meaning, and less force in relation to costs in "our town."

And how can the small town listener keep his attention on the argument for public health services when we bring in comparisons with expensive "per capitas" for fire and police protection of which he has so little.

May those who write and those who speak give earnest attention to how to make "per capita" significant and convincing.

Health Education—The following are listed in *Library Index*, 450-7th Ave., New York:

We Should Know Them—Two new committees of the National Conference of Tuberculosis Secretaries are of interest to this department:

Child Health Education: Edna Bond, Newark, N. J., chairman; Jean Latimer, Boston, Mass., Mrs. Blanche de Koning, Grand Rapids.

Health Education: Robert W. Osborn, Buffalo, chairman; William F. Higby, San Francisco; Rowan Whealdon, Newark, N. J., secretary; Dr. Henry D. Chadwick, Detroit, medical consultant; Dr. Iago Galdston, New York, staff adviser.

A Use for Your Photographs—They may not be "cure" pictures but they may illustrate a situation or an idea suitable for *Journal of the Outdoor Life*, 450 7th Ave., New York, N. Y.

The Journal of the Outdoor Life pays a slight honorarium for any photographs suitable for publication submitted by its readers. They are judged (1) according to their subject matter, namely, human interest scenes dealing with some phase of curing, whether at home or in a sanatorium, and (2) for their technical excellence and reproducing qualities. Please secure written permission from anyone whose picture you are submitting and tell us where it was taken.

By the way if you have not seen the new *Journal of the Outdoor Life*, you will wish to ask for a sample copy to see the transformation due to careful planning of paper, typography and pictures.

The "Women's Crusade" for Human Needs—A nation-wide educational movement being organized to supplement the fall and winter community chest fund raising campaigns, as well as to supplement all legitimate efforts for the maintenance of essential health and other welfare services, public as well as private, will affect health work.

This is the Women's Crusade, the National Women's Committee of the 1933 Mobilization for Human Needs. Newton D. Baker is chairman of the National Citizens' Committee, and Mrs. Franklin D. Roosevelt, chairman of the National Women's Committee, with headquarters in Room 1815, Graybar Building, New York, N. Y.

Inspiration for the plans offered to local committees comes from the Women's Crusade which so notably supported the April, 1933, campaign of the Cincinnati Community Chest.

The purpose of the Women's Crusade is educational, not financial. It seeks to interest more women in the welfare work of their communities; to help women understand its problems and aims, especially as these have been affected by recent changes; and to guide women in stimulating public opinion toward a generous meeting of human needs through their local fund-raising agencies.

These aims are to be accomplished through informal discussion, public speaking, answers to criticism, distribution of literature, and other measures as agreed upon with the local community chest or other welfare campaign, of which the Women's Crusade should be a closely linked part.

The immediate purpose is to provide an educational background for local community efforts to raise funds for the agencies not supported by taxes. Inci-

dental to this purpose it will be necessary in many communities to interpret the needs, resources, and relationships of the public agencies. And it may be expected that later the same local Crusade groups, with their understanding of community problems, and their fine enthusiasm for service will be available as the public services face critical situations.

Local health workers may well get in touch with the local Crusade groups as they are organized. If organization is delayed write to the National Women's Crusade Committee stating the situation and suggesting capable women for local leadership. A copy of the Crusade handbook will be sent upon request to the National Women's Committee without charge to the local leader. Price to others, 10 cents; special price for quantities.

Eight of the cooperating national organizations are concerned with public health.

Why Not?—This from *Public Health Nursing*, New York (Sept., 1933):

In examining school children why send a note home to the parents only when there are defects? Why not also when the child is in good condition? This has been tried in several places with excellent psychological effect on the parents. For example—"John was examined by the school physician today and was found to be in excellent physical condition. You are to be congratulated on the good care you are giving him and trust you will continue it." Can't you see the parent swelling with pride at this; and also the envious glances of neighboring parents whose children had some defects, and the subsequent scrambling on their part to get the defects corrected as soon as possible?

This is one of the many valuable points brought out in the Health Education Conference held in Ann Arbor, Michigan, in June, under the auspices of the American Child Health Association.

Health Advice in Newspapers—The "Annual Directory of Features"

(*Editor and Publisher*, New York. Aug. 26, 1933. 10 cents) lists the following:

"Health," Dr. Morris Fishbein; "Health," Dr. Copeland; "Health Column," Dr. W. A. Evans; "Health Column," Dr. Logan Clendening; "Health Column," Dr. Iago Galdston; "Health and Beauty," Dr. Sophia Brunson; "Health, Heart and Home Page," unsigned; "Here's to Your Health," Dr. Frank McCoy; "How I Keep Fit," Celebrities; "How's Your Health," Dr. Iago Galdston; "How to Reduce Without Dieting," Lilyan Malmstead; "Secrets of Health and Success," Dr. Louis E. Bisch; "That Body of Yours," Dr. James W. Barton; "Your Child's Health," Dr. Michael Shuman; "Your Eyes, Ears, Nose and Throat," Dr. H. Hoare; "Your Good Health," Dr. Claud North Chrisman; "Your Health," Dr. Royal S. Copeland; "Your Weight and Your Height," Dr. James W. Barton.

In addition, classified under "Food" are the following and others:

"Eat and Grow Thin Diet," Dorothy MacLennan; "Food and Health," Dr. Shirley Wynne; "Mrs. Babe Ruth's Diet"; "Pure Food Articles," Dr. Royal S. Copeland; "Thirty-Day Diet."

The lists are given here to show the extent and the sources of the material sold to daily newspapers in the United States and Canada. The contributions classify as good, not so good, indifferent, and bad.

In *Hygeia* for September, 1933—are the following—and other articles:

"Football Injuries"; "Colleges and Health"; "Are They Ready for School?" "Removing Rural School Handicaps to Mental Accomplishments"; "The Mother and the School"; "Sex Education": Part III; "What Your Child Eats at Noon"; "Can School Days Be Safe Days?" "Training for Athletics and Health"; "Progress in Preventive Medicine"; "School and Health" (including "Projects in Teaching Health Originated by Southern Illinois Normal University"); "Let Us Go to the Foot Carnival"; "Building a Health Village"; "Let History Live!" "Pigs Help to Teach Hygiene"; "Combining Music With Health"; and "New Health Books and Teachers' Materials."

EDUCATIONAL MATERIAL

"What Builds Babies? The Mother's Diet in the Pregnant and Nursing Periods." Children's Bureau, Washington, D. C. 7 page folder. Revised edition. Single copies *free*.

"Mother's Milk — Summer Complaint," reprinted from *Hygeia*, June, 1923 and June, 1933. American Medical Assn., 535 N. Dearborn St., Chicago. 32 pages. 15 cents; quantity rates. Popular and practical; several attractive illustrations.

"Appendicitis." John Hancock Mutual Life Insurance Co., Boston. 5 small pages. *Free*. Explains and emphasizes the following:

In the presence of abdominal pain, give nothing by mouth. Never give laxatives. Apply an ice pack. Call your family physician. Abdominal pain which persists over a period of 6 hours is usually serious.

"Milk for the Family." *Farmer's Bulletin* 1705. 30 pages. Supt. of Documents, Washington, D. C. 5 cents. Probably *free* from Dept. of Agriculture, Washington, D. C. Supersedes "Milk and Its Uses in the Home." Values of, choosing, home care of milk, etc.

"Children's Bureau and Other Publications Relating to Children." Supt. of Documents, Washington, D. C. 15 pages. *Free*. Classified list of U. S. Government publications.

"Salt for Oral Health," by H. T. MacDonald. *Health*, Canadian Social Hygiene Council, 105 Bond St., Toronto, Ont., June, 1933. 15 cents. "Ordinary table salt seems to fulfil the requirements of a good dentifrice. Here is the story of why this is true."

Have you passed on to local outdoor recreation leaders the article on "Loss of Actinic Sunshine as a Health Problem of Cities," by Dr. F. O. Tonney (in August, 1933, *Journal*)? Of course, marking the second suggestion on page 780. An editorial writer on one of your local newspapers might welcome an

opportunity to discuss material in that article.

Nutrition Notes, issued September to June, is a little publication of great value to those who desire "brief mention of newer findings in the field of nutrition, with suggestions for feeding families at low cost." 50 cents a year; 8 cents a copy. Nutrition Bureau, A.I.C.P., 105 East 22d St., New York, N. Y.

We have been favored with a set of post cards on the prevention of accidents, issued by Instituto de Reeducación Profesional, Madrid, Spain. The illustrations show that many accidents in Spain as well as in the United States result from carelessness as well as the lack of safety devices.

Single copies only to health workers outside the state will be supplied by Massachusetts Dept. of Public Health, Boston:

"Why Be Vaccinated?" 4 pages, with several striking diagrams.

"Food for the Teens," 8 pages. What foods are sources of this and that; 3-page table of the form in which specified foods may be eaten and their values; table of calories; etc.

"Caring for Teeth" and "Eating for Teeth." 2 pages.

"The Permanent Teeth." 2 pages; 2 diagrams.

"How to Judge Nutrition of Children." 1 page. "The well nourished child shows . . ."

"The Control and Prevention of Rabies." 6 pages.

"Good Eating Habits." 4 pages. Habit training; how to make certain foods more acceptable.

"Recipes for Cracked Wheat." 1 page.

"Epidermophytosis (Athlete's Foot): Its Prevention and Treatment." 5 pages.

Metropolitan Life Insurance Co., New York, N. Y., and Ottawa, Ont., will supply the following:

"The Custodian and the School Child." 16 pages. The janitor as a health worker.

"Tonsils and Adenoids. Is Your Child Handicapped?" 4 pages. Delightful child face on the cover.

"Your Little Child Goes to School. A Message to Fathers." 8 small pages. At last "father" is getting his share.

"The Safe Walker's Memo Book." 16 pages, partly blank. Red and black diagrams on walking in city and country. "When the pages have been filled, the local representative of the Metropolitan Life Insurance Company will be glad to furnish a new booklet."

"The Real Driver's Log Book." 18 small pages. Pages for recording your trip; text and illustrations on "The Art of Driving."

"Check Your Car for Safety and Performance." 22 small pages. Blank forms for records; text and series of questions as to safety precautions for car owner.

"Protection of Workers Exposed to Chromium and Its Compounds." 15 pages.

"Organizing for a Traffic Survey." 24 pages.

"Studying the Movement of Vehicles." 24 pages.

"Finishing the Job in Diphtheria Prevention," by Donald B. Armstrong. 6 page reprint. What more to do in New York—and elsewhere.

"The Tuberculosis Movement Today," by Donald B. Armstrong. 5 page reprint.

Again comes "Statistical Report of Infant Mortality for 1932 in 955 Cities of the United States," issued as usual by American Child Health Association, 450 7th Ave., New York, N. Y. 31 large pages. Single copies *free*. The interpretive comment adds much to its value for use in publicity.

"Reducing the Public Health Budget" was presented over an NBC-WJZ network on Sept. 5. George F. Canfield, Dr. Matthias Nicoll, Jr., and Dr. Kendall Emerson were the participants. Copies of the discussion for 15 cents from National Municipal League, 309 East 34th St., New York, N. Y.

Readers of this department who serve on the firing line in the actual production of copy will find serviceable background material in every issue of the *Journal*. Not to be overlooked is "A Selected Public Health Bibliography With Annotations," edited by Dr. Raymond S. Patterson.

"Services the Health Bureau Renders to the Public and Physicians" is a three-page tabulation classified under 20 headings. Quite a worth while idea for, say, once a year in the house organ of the public or private agency. *Bulletin*, Health Bureau, Rochester, N. J. July, 1933.

"Syphilis" was the subject of a broadcast over WFEA, Manchester, N. H., by Dr. H. W. N. Bennett, State Board of Health Clinic. Reproduced in *Health*, State Board of Health, Concord, N. H. July, 1933.

What is probably a fairly common phase of the rat problem is illustrated on the cover page of *Municipal Sanitation*, 24 W. 40th St., New York, N. Y. Aug., 1933. 25 cents. Photographs of similar dump piles could be used effectively in calling attention to such situations: "Water, food and shelter, and ideal layout for developing a plague of rats."

SCHOOLS AND CHILDREN

To those concerned with health teaching in the schools: re-read the first two paragraphs under "Health Education Conference at Ann Arbor," page 873, in the *Journal*, Aug., 1933.

The third issue of *Spyglass* was issued Sept. 15 by American Child Health Assn., 450 7th Ave., New York, N. Y. 75 cents for 4 issues.

"This periodical for children will help them bring into focus with their everyday living and health problems, important and useful information from a variety of sources.

The September issue contains timely material suitable for use in connection with the fall health activities in the schools. Illustrated.

Some of the school health articles in *Public Health Nursing*, 450 7th Ave., New York, N. Y. (Sept., 1933. 35 cents):

"A Health Program in a Private School"; "Evaluating the Home Visit"; "First Aid as It Affects Nurse or Teacher Load."

Significant features of the Seventh

Health Education Conference, at Ann Arbor last June, are brought out by Anne Whitney in *Child Health Bulletin*, American Child Health Assn., 450 7th Ave., New York, N. Y. Sept., 1933. The Conference "was unique in that it did not go on record as endorsing any formal resolutions or statements."

Two reasons for this might be suggested. First, the recent White House Conference on Child Health and Protection has crystallized for those working in health education a vast amount of material which offers a substantial body of standards and principles useful for many years to come. Second, the unpredictable elements in our present social and economic conditions have given workers a realization of a need for clear thinking and for flexibility in adaptation to changed conditions.

The same issue of *Child Health Bulletin* includes: "The Relation of Food to Health," by Mary Swartz Rose; "Coöperation in Health Work," by Kendall Emerson; "Health Education of Teachers: Some Trends in Their Preparation," by Ethel M. Mealey; "Evaluation of School Health Procedures," by George T. Palmer; "Child Health Literature," a bibliography of current material; "The Care of the Mother Before the Baby Comes—And Afterwards," references selected by Clara E. Hayes. The two sections, "For Parents" and "For Physicians and Nurses," are each divided under "Single Copies Free" and "Books and Pamphlets to Be Purchased Directly from Publishers or Local Booksellers." This last is a new and helpful addition to the details which characterize A.C.H.A. reference lists for making them easily usable.

This from the mast-head of *Safety Education*, 1 Park Ave., New York, N. Y., expresses the standard set up for safety work with children:

Life is made up of adventures; even crossing the street is an adventure! Some adventures are good and necessary. Others are

stupid and futile. Some bring the more abundant life. Others bring only waste of life and the material resources of life. . . . All adventures involve uncertainty and danger. A danger courageously met and intelligently controlled is part of the substance of a normal life. A danger carelessly met and ineffectively controlled results in defeat of purpose and even in tragedy. . . . This magazine is primarily for the use of schools in helping children choose their adventures wisely and in helping them carry these adventures through intelligently.

PLAYS

"Chasing Germs." *Jamaica Public Health*, Kingston, Jamaica. Sept., 1933. Real folks; no fairies, no impersonation of germs!

"Three Pairs of Shoes," by Marion Holbrook. *Safety Education*, 1 Park Ave., New York, N. Y. Sept., 1933. 10 cents.

MAGAZINE ARTICLES

"The Baffling Struggle Against Tuberculosis," by Dr. Kendall Emerson. *Literary Digest*, New York. Sept. 2, 1933. 10 cents.

"Beauty Without Bunk," by Dr. Ruth F. Wadsworth. *Collier's*. July 29, 1933. "Real beauty culture encourages Nature instead of attempting to improve it."

YOU MAY BE INTERESTED

Those who are doing industrial health work will wish to get acquainted with *Industrial Medicine*, 844 Rush St., Chicago.

"In keeping with the spirit of the times this report was inexpensively prepared" in mimeographed form, says The Brooklyn Tuberculosis and Health Assn., 293 Schermerhorn St., Brooklyn,

N. Y. Pages are 5½ by 7½ inches. An effective page appeal for bequests—so frequently omitted. It is interesting to note that \$26,613 of the \$79,829 budget went for "Health Education and Promotion," the details of which are listed.

The September, 1933, convention of American Hospital Assn. included a "Round Table on Public Relations" with a "Report of Public Relations Committee," "Discussion of Proposed Program of Public Relations for Ensuing Year," "A Practical Basis for a Public Relations Program," "Presentation of Complete Public Relations Program," "Educating the Public Through Lantern Slides and Motion Pictures," with demonstrations. The "Round Table on Administrative Problems" included "How Can the Public Be Educated as to the Cost of Good Hospital Service?"

"Empire Health Week," announced for Oct. 1-7, 1933, established in England in 1912, has been observed in Jamaica since 1923. *Jamaica Public Health, Kingston*, says that

"Empire Health Week has been observed in Jamaica since 1923, and each year has shown an increase in the number of communities which have carried out programs of health education. And each year more and more people have during this week given consideration to questions of hygiene and sanitation at homes and schools. Doctors, preachers, teachers, lawyers, planters, officials and leading citizens have taken part and given talks on disease prevention. It is worthy of note that schools in every part of the Island have year after year prepared special programs, and in other ways taken an active part in carrying health teachings into the homes of each district. The topic of special study for Jamaica for the Health Week of 1933 will be Safe Water."

BOOKS AND REPORTS

Tuberculous Disease in Children: Its Pathology and Bacteriology—
By John W. S. Blacklock. London: His Majesty's Stationery Office, 1932. 155 pp. Price, \$1.00.

This highly interesting special report of the Medical Research Council by a student of the pathology of adult tuberculosis is an attempt to throw some light upon the paths of infection, their correlation with the type of tubercle bacillus, and the relative importance of air-borne and food-borne infections.

The author's material consisted of 283 cases of naked-eye evidence of tuberculous infection among 1,800 consecutive autopsies and 65 cases of surgical tuberculosis. Of the 283 children autopsied, over 90 per cent died from tuberculosis and the organism was isolated in 183 instances. Of the cases of surgical tuberculosis, 52 strains were isolated from 65 cases. In all, 241 strains were isolated (152, 63 per cent, were human type). Relatively fewer males (13.9 per cent) than females (19 per cent) showed lesions of tuberculosis and from the second year onward the percentage was always higher in females.

Among the 283 cases the site of the primary infection was considered probably to be thoracic (lungs or lymphatic glands) in 61 per cent, most frequently situated in the right upper lobe, which was difficult of explanation. When the primary infection was in the abdomen, bovine bacilli were found in 82 per cent; when in the lungs, human bacilli were present in 97 per cent. One-third of the children with bone and joint tuberculosis had a bovine infection and among all the children with

bovine infection such lesions were 13 times as common as among those with primary thoracic tuberculosis.

Air-borne infection is more common in cities, and 86 per cent of the children with primary thoracic tuberculosis lived in cities.

Thus from the pathological, histological and bacteriological points of view, the primary lung lesion would appear to be, indeed, such and due to direct infection of the lungs through the air passages. We do not deny—and, as a matter of fact, have shown—that in some cases of primary abdominal tuberculosis severe pulmonary lesions may be found, but these are of a secondary nature.

The author feels that in Scotland, in marked contrast to the experience in America and on the Continent, nearly all children with tuberculous lesions in the lungs or tracheobronchial glands die in childhood from tuberculosis. It is possible that the Scots are less resistant than many other races.

In 101 cases (36 per cent) of the 283 coming to autopsy and dying from tuberculosis, the primary lesion was probably in the intestines. In 18 under 5 dying from tuberculosis all had intestinal ulceration. All such cases under 1 year had been fed on cow's milk. The greatest number of primary abdominal lesions were found in the second year of life, that is, at the period when children are consuming large amounts of raw milk. From these abdominal lesions, 12 human and 54 bovine strains were isolated, country children showing slightly more bovine infection, due possibly to the fact that the milk in Glasgow is pasteurized. From children dying from tuberculosis 165 strains were isolated, 73 per cent being human. The greatest percentage

of human strains as compared with bovine was found in the first 6 months of life, and in children from 5 to 13. The highest percentage of infections with bovine strains occurred in the second year of life, when most raw milk is consumed. There was some evidence to show that the bovine was less dangerous than the human strain. Probably both the situation of the primary lesion and the type of bacillus have something to do with the generalization of the disease which occurs more frequently associated with the human bacillus.

This valuable study has added many concrete facts to our still somewhat confused knowledge of childhood tuberculosis. It again emphasizes the importance of the bovine tubercle bacillus in the struggle against tuberculosis. It may be recalled that in 1901 Koch questioned this importance but modified somewhat his views in 1908. In the meantime Ravenel, Griffith and others had shown that for children, at least, the bovine bacillus was very dangerous.

Blacklock adduces convincing evidence that such is the case and even in America it has been estimated that 3,000 to 4,000 children die from the bovine tubercle bacillus annually. For man, Blacklock thinks he has shown that the bovine infection is less pathogenic than the human type but evidence is accumulating that at least in Scotland the bovine bacillus may be found in over 3 per cent of the cases of adult pulmonary tuberculosis, due, Griffith and Munro hold, to a late manifestation of a childhood, bovine, alimentary infection. Such patients rarely, they have suggested, infect others. Apart from the generalized tuberculosis occurring in the children with little resistance, Blacklock found pulmonary lesions are the most dangerous manifestation of tuberculosis. These are nearly always due to the human

bacillus, from aerogenous infection. Bovine infection is more common in Scotland than elsewhere and apparently infantile tuberculosis is almost always fatal. He thinks it is very rare for dormant infection of childhood to flare up later.

It is impossible to give in a small compass the many important and suggestive facts brought out in this work. The book should be carefully studied by all who are engaged in health work and is particularly to be recommended to the workers in tuberculosis.

LAWRASON BROWN

A Standard Classified Nomenclature of Disease—*Compiled by the National Conference on Nomenclature of Disease. Edited by H. B. Logie, M.D., C.M. New York: Commonwealth Fund. 701 pp. Price, \$3.50.*

This book is the product of coöperative effort by national organizations representing medicine, medical statistics, surgery, public health, and industrial hygiene; by the federal medical, health, and statistical services, and life insurance interests.

This nomenclature is a distinct advance over all nomenclatures that have preceded it; and it is a decided departure therefrom in that it provides for the classification of diseases on a dual basis, that is, etiological and anatomical. This makes it possible for hospitals to make statistical accountings of *all* the diseases affecting any organ of the body; and for the first time, hospital statistics showing both the site (except when unknown) and cause (except when unknown) of disease will become available.

The new nomenclature is divided into 11 anatomical divisions and 11 etiological categories. Leading specialists in all branches of medicine have given generously of their time to assist in its preparation. All acknowledge, never-

theless, the outstanding contribution which has been made by Dr. H. B. Logie in originating the dual form of classification and in preparing and editing the manuscript of the book itself.

The *Nomenclature* is to be kept abreast of the progress of medicine. This will necessitate revisions from time to time. For this purpose the National Conference on Nomenclature of Disease will continue to function and an executive staff will be maintained. Headquarters will be at the New York Academy of Medicine which has generously provided office space and working facilities since the Conference began its work.

The reception of the *Nomenclature* by clinical societies and hospitals has been most gratifying. More than twenty of the former have approved it formally. It is now in actual use in 71 hospitals, including many of the largest in the country; and its adoption is being considered by 238 additional hospitals. A number of large hospitals associated with leading medical schools are using it. Among these may be mentioned Harvard, Columbia, Yale, University of Pennsylvania, Western Reserve, Vanderbilt, Tulane, and the University of Chicago. More recently its use has spread to other countries, through its adoption by hospitals in Palestine and the Dutch East Indies.

GEORGE H. VAN BUREN

The History and Epidemiology of Syphilis—By William Allen Pusey, M.D. Springfield, Ill.: Thomas, 1933. Price, \$2.00.

Anything from the pen of Dr. Pusey on syphilis is authoritative and written in a style which attracts. The present volume consists of three lectures given under the Adolph Gehrman Endowment, and according to the author, are an elaboration of certain chapters of his monograph on *Syphilis as a Modern*

Problem, written in 1915 as a part of the celebration of the Panama-Pacific Exposition at San Francisco. The changes consist chiefly of bringing the material up to date, since much new matter has come to our knowledge in the 18 years which have elapsed since that publication.

The book is written in Dr. Pusey's usual style, succinct and interesting. We have already said that it is authoritative. It is profusely illustrated, with old cuts and 26 photographs of well known men who have taken part in the study of syphilis and the elucidation of the problems presented.

The printing and make-up are excellent.

MAZÛCK P. RAVENEL

Cancer and Other Chronic Diseases in Massachusetts—By George H. Bigelow and H. L. Lombard. Boston: Houghton, Mifflin, 1933. 355 pp., 135 tables, 12 charts, and 2 maps. Price, \$4.00.

The shift in age classes in the population due in part to the reduction in infant mortality and to the growth of preventive medicine, is affecting the incidence and amount of chronic diseases to such a degree that the problem of hospital or other care for this group of persons is becoming a social, economic and medical problem of increasing importance.

The population over 50 years of age has increased about 1 per cent in each decade. Deaths from chronic diseases have increased from one-third of all deaths 50 years ago to two-thirds today. The duration of such diseases in persons over 50 years of age has increased 2.6 times in the last 20 years.

The time lost by wage earners due to chronic disease in Massachusetts annually is valued at \$40,000,000. Chronic cases to the number of 55,000 occur annually in that state in homes wholly unable to care for them. This number would require 18,000 hospital

beds and an initial investment of \$55,000,000 for their installation and \$18,000,000 for maintenance, with a net cost to the state after estimated receipts are credited of \$13,000,000—nearly one-third of the present cost of state government.

As alleviating factors, the following proposals are discussed: (1) a program of adult hygiene to be added to that of childhood and adolescence to constitute a health education program in schools; and (2) early diagnosis, especially in cancer. Discriminating short-term medical service is less expensive than indiscriminate long-term service to the ambulant invalid or to society. There are 138,000 cases of rheumatism in Massachusetts, of whom 70 per cent receive no medical care, and of whom 70 per cent could probably be benefitted by proper care.

About 12 per cent, or 500,000, of the population in Massachusetts are victims of chronic disease. Of these, 45 per cent are partially disabled and 5 per cent totally disabled. The incidence is 50 per cent higher among the poor than among the well-to-do.

The order of incidence is rheumatism (138,000), heart disease (84,000), arteriosclerosis (64,000), digestive diseases (29,000), eye and ear (24,000), apoplexy and tuberculosis (24,000 each), diabetes (15,000), and cancer (11,500). The duration varies from cancer at 21 months to rheumatism at 4 years. The fact that rheumatism cripples most and lasts longest makes it of preëminent social, economic, and medical importance. At present two-thirds of this group receive no medical attention. The reasons given for absence of treatment were (60 per cent) lack of confidence in medical treatment, (33 per cent) condition not regarded as serious, and (13 per cent) economic reasons.

The Massachusetts cancer program is reviewed in the light of 5 years' experi-

ence. This provided state-aided cancer clinics and a state hospital for treatment of the indigent and to stimulate more adequate diagnostic and therapeutic service.

The review indicates that the services of the best medical and lay citizens can be obtained to develop and guide a cancer program; that physicians respond to the educational opportunities and their patients to clinics and hospitals; that cancer patients come in large numbers to private agencies when informed; that earlier use of cancer diagnosis follows on importunity; that all methods of public information on cancer must be used unceasingly; and that under government direction clinic and hospital service can be developed of a quality not heretofore available. Similar services should be developed for other important chronic diseases.

This study was made by the Massachusetts Department of Public Health, and is based on a large volume of statistical information elaborated with skill and a notable completeness. Every public health official and worker should be familiar with its findings and ponder over it.

CHARLES A. KOFOID

The Sanitary Inspector's Handbook. A Manual for Sanitary Inspectors and Other Executive Public Health Officers—By Henry H. Clay. London: H. K. Lewis & Co., Ltd., 1933. 386 pp. Price, \$4.00.

This is one of the books which give joy to a reviewer. Prepared with the idea of supplying a textbook for students presenting themselves for the examination of the Royal Sanitary Institute and Sanitary Inspectors Examination Joint Board, it necessarily deals with English customs and laws. However, the book is soundly based on fundamentals and each chapter gives the reference to the Public Health Acts involved. It will not only be of much value to students in England and

Scotland, but to those in the United States, while every public health officer will find practical, sound sense based on fundamentals which are as true for America as they are for the British Islands. For example, early in the volume a chapter is given to "Powers of Entry." These powers are based on common law, as we understand it, but necessarily the statutes in England are different from those in our country.

From cover to cover the book is full of sound information which will be of great value to inspectors or health officers in this country and elsewhere as well as in England. In spite of these drawbacks, as they may be called, for the American reader, the book can be unreservedly recommended to all of those interested in inspection and enforcement of sanitary law.

It is excellently printed and well illustrated. There are chapters on vital statistics, useful memoranda and glossary of building terms, tables of measurement with their equivalents in different systems, etc., all of which add to the convenience of the reader.

MAZYCK P. RAVENEL

Everyday Problems in Health—

By Frank Merrill Wheat and Elizabeth T. Fitzpatrick. New York: American Book Company, 1933. 144 pp. Price, \$1.20.

"A basic text planned for the scientific teaching of pupils either in junior or senior high schools" is a concise but inadequate description. My own description from a purely human point of view would be, "an absorbing book, presenting vividly subject matter of interest to every human being."

The book of 440 pages, including appendix, glossary and index, is not only an excellent basic text, logically arranged and carefully checked, but is also an unusually challenging presentation of problems of biology, public

health and social relationships common and vital to everyone.

Divided into five units, Health and the High School Pupil, Eat and Live Healthfully, Putting Food to Work, The Control of the Healthy Body, Maintaining a Healthful Home, each unit is subdivided into Problems which cover a large range.

The book is written for high school students and is presented by authors who have such a keen interest and love of the human animal, not as a cut and dried subject, but rather as a living and thinking organism, that it seems inevitable that physiology, biology, and everyday living will be real and vivid experiences instead of lessons to be learned laboriously and perhaps distastefully.

This book meets a long felt need in high schools and will, I am sure, call forth from teachers and parents the remark which it called forth from me—"At last a health text which will bring results in better living."

JULIA B. TAPPAN

The Health School on Wheels—

By J. Mace Andress and I. H. Goldberger. New York: Ginn, 1933. 399 pp. Price, \$.76.

If any book can arouse the interest of children in public health, *The Health School on Wheels* should do it.

There is nothing new in the idea of sightseeing tours of a city, but to adapt them to one class of school and to specialize in the health promoting agencies of a large city is a suggestion with real merit. It may not be that every class which uses this book as a text can study at first-hand the aspects of community health as the children do in the story—in fact, relatively few cities have all the opportunities afforded by "Brightville." However that may be, the desire to know more about what is going on along this line should certainly be created.

The suggestions for newspaper publicity talks by city officials, school health leagues, public boards, and illustrated notebooks may well play a part in the activities of the class just as they do in the story.

Any wide-awake teacher will find this book a valuable guide full of helpful ideas for civic instruction. Health officers can use it to good advantage in planning demonstrations of what their departments do. Popular interest and coöperation are essential, if public health work is to be at its best.

JOHN HALL.

Infants and Children: Their Feeding and Growth—By *Frederick H. Bartlett, M.D.* New York: Farrar & Rinehart, 1932. 409 pp. Price, \$1.50.

This is one of the best books of the sort that I have come across. In the first place the format is good. Then it is possible to find things in it: it has an excellent table of contents and a comprehensive index. It is written in an agreeably personal style without the *ex cathedra* attitude which is so characteristic of some books written for the laity. The intelligent mother can read it without irritation. It goes into considerable detail, with enough repetition to drive home the point but without wordiness.

One of the best chapters of the book is on Habits. Some very sane advice is given there which ought to alleviate the anxiety of a certain type of parent. The emphasis laid on prevention is most commendable. In the chapter on Emergencies, however, the paragraph on Dogbite is inadequate in view of the prevalence of rabies and sentimentality in this country. In the chapter on Feeding, on pages 46 and 47, there is a slight inconsistency in the recommendation regarding the use of egg yolk. Again, the wording of the reference regarding the use of evaporated milk

gives the impression of over-conservatism, perhaps.

All in all, this manual can be recommended unreservedly for the use of any mother who takes her job seriously.

MERRILL E. CHAMPION

A Study of Rural Public Health Services—By the *Sub-Committee on Rural Public Health Work and the Committee on Administrative Practice of the American Public Health Association.* Allen W. Freeman, M.D., Editor. Published by the Commonwealth Fund of New York. 233 pp. 84 tables. 6 ill. Price, \$2.50.

This authoritative book on rural public health services in the United States and Canada is the first comprehensive review of the subject to appear in the literature of rural public health administration. It will be welcomed as a companion volume to earlier publications covering similar studies for city, state, and provincial health departments.

In the development of a tentative appraisal form for rural health organizations in 1927 the need for more accurate and basic knowledge of rural health services became apparent. The Committee on Administrative Practice of the American Public Health Association decided to undertake such a study, and a sub-committee was appointed. Financial assistance was secured through the Commonwealth Fund, and the detailed planning of the survey began in 1928. Dr. C. B. Crittenden's services were secured for personally surveying 27 typical organized and 19 unorganized counties in 28 states and 2 Canadian provinces. Furthermore, to provide a check on the representative character of the data collected for surveyed organized counties, 467 county and district whole-time health organizations were circularized with questionnaires to be filled in as for the year 1929, and

337 of those returned were analyzed. In the text the former group of counties are referred to as "surveyed counties" and the latter as "coöperating counties."

The preface to this volume is an excellent introduction to the report and will repay careful study. The first chapter is a summary of the main points of interest disclosed, and the second chapter is devoted to the background of the survey. In the thirteen chapters which follow attention is given to matters of organization, health services performed by the state, personnel, expenditures, communicable disease control, maternity hygiene, infant and preschool hygiene, school hygiene, general sanitation, and health instruction. The material for these chapters is discussed separately for the surveyed group and the coöperating group of counties.

The average area of the surveyed counties in the United States was approximately 1,100 square miles; the average population was nearly 38,500; and the average density of the population was 35 persons per square mile. More than 61 per cent of the total population of the 44 American counties surveyed was rural, and 36.4 per cent was rural farm population. Only 8 of the 44 counties had a per capita income in 1925 greater than the \$750 average for the United States, and nearly one-fourth of the coöperating counties included in this study had an average per capita income of less than \$200.

Only one-fourth of the surveyed counties had a separate board of health. Organized counties of the surveyed group had 1 nurse per 12,500 population. In unorganized counties there was 1 nurse per 16,000 persons, and in

coöperating counties 1 nurse for 16,500 persons.

In the surveyed group the average annual expenditure for organized counties amounted to \$18,748 or \$.475 per capita. This was 1.5 per cent of the total cost of county government. For unorganized counties surveyed the total cost was \$6,380. In the coöperating counties the average annual expenditure per county was \$12,060 or \$.378 per capita.

. . . The solution of the problems of the rural health administration in the United States seems to depend upon the extension of the system of county health departments. Such county health departments must be staffed and financed more adequately than at present, and the position of county health officer must be made to offer a satisfactory career to young and well trained physicians who wish to make of health administration a life work.

The report should be of special interest and value to local rural health workers and directors of divisions of local rural health administration of state and provincial departments of health. To those actively engaged in rural health work it will contribute to breadth of vision, awaken interest in the character of information which should be collected and analyzed periodically for each unit, suggest indices for evaluating health services in terms of activities, and in general help to coördinate the separate units of the rapidly growing rural health administration movement.

Readers of this excellent report will be grateful to the American Public Health Association, the Commonwealth Fund, and to all others who have participated in its accomplishment for the high character of the services rendered.

W. A. McINTOSH

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Seasonal Conjunctivitis—The deep South adds a new sanitary problem to the long list of its health services in the eradication of "eye-gnats" and the resulting "gnat eye disease." Adequate garbage and feces disposal combined by a simple treatment are the indicated preventive measures easier to enumerate than to apply.

BENGTSON, I. A. Seasonal Acute Conjunctivitis Occurring in the Southern States. *Pub. Health Rep.* 48, 31:917 (Aug. 4), 1933.

The Troublesome Typhoid Carrier Problem—Typhoid carriers of over a year's duration, in whose bile are found the bacilli, may well have the operation for the removal of the gall bladder at public expense, for it is cheaper and more effective than subsidy. In the Massachusetts series reported, stones were found in all carriers and the symptoms associated with the condition were relieved.

BIGELOW, G. H. and ANDERSON, G. W. Cure of Typhoid Carriers. *J.A.M.A.* 101, 5:348 (June 29), 1933.

When Thirty Days Is Too Long—Uncomplicated cases of scarlet fever may be terminated on the 21st day with but little, and on the 25th day with no more, danger to the community than on the 30th day. Complicated cases should be isolated until cleared up. Isolation for 7 days after the end of contact should be enforced.

BREST, W. H. A Study of Secondary Cases of Scarlet Fever. *New York State J. Med.* 33, 14:881 (July 15), 1933.

Penalties for Being Fat—Physical impairments in a group of men, including both underweights and overweights, correspond in incidence to previously established mortality rates due to the same conditions. On the underweight side we have tuberculosis out-

standing, and on the overweight side are the degenerative conditions indicated by urinalysis findings and high blood pressure.

BRITTEN, R. H. Physical Impairment and Weight. *Pub. Health Rep.* 48, 31:926 (Aug. 4), 1933.

Getting Action in Health—Exactly what, and who, and how to tell the story of health is the burden of this discussion of health education.

BROWN, B. Mass Education. *Milbank Quart. Bull.* 11, 3:163 (July), 1933.

Scarlet Fever Immunity Lasts—Eight years after they were immunized, 50 formerly Dick positive children were retested. Thirty-two were still Dick negative while 18 were slightly positive.

BULL, H. G. Report on a Group of Fifty Children Dick Tested Eight Years After Immunization Against Scarlet Fever. *J.A.M.A.* 101, 5:363 (July 29), 1933.

Encouraging Increase in Treated Syphilis Cases—In 1927 prevalence surveys indicated that 643,000 cases of syphilis were constantly under treatment. Now it is estimated that 423,000 fresh cases are gathered in for treatment each year, and an equal number are beginning treatment for infections of long standing. An upward trend in this curve is considered encouraging.

CLARK, T. and USHINGTON, L. J. Trend of Cases of Syphilis Under Treatment or Observation in the United States. *South. M. J.* 26, 8:722 (Aug.), 1933.

Doctoring the British Tommy—A symposium of varied opinions on the proposal of a general medical service for Great Britain which now spends 200 million pounds per annum. The preventive angle is much in evidence.

COX, A. *et al.* A General Medical Service for the Nation. *J. Roy. San. Inst.* 54, 2:52 (Aug.), 1933.

Raw Milk and Streptococci—Another milk-borne outbreak of scarlet fever is reported. The 57 cases of scarlet fever and 38 cases of sore throat were the result of a streptococcal udder infection in a cow. The milk, of course, was not pasteurized.

FEEMSTER, R. F. and KINGSTON, J. M. A Scarlet Fever Outbreak Due to Raw Milk. *New Eng. J. Med.* 209, 6:275 (Aug. 10), 1933.

Vitamin A Supplements Not Needed—"In the course of an observational period of 5 months, frequent respiratory infections developed . . . among those receiving vitamin A to the same extent as among the control group. . . . There is no clinical basis for designating vitamin A the 'anti-infective vitamin.' . . . Our dietary is not deficient in vitamin A."

HESS, A. F. *et al.* Does Our Dietary Require Vitamin A Supplement? *J.A.M.A.* 101, 9:657 (Aug. 26), 1933.

Tuberculin Testing of Rural Youngsters—In a rural community like Cattaraugus County, the infrequency of tuberculosis in elementary grade school children makes the routine adoption of the expensive and time-consuming tuberculin test seem unwarranted. It is desirable among all high school students and contacts of diagnosed cases.

KORNS, J. H. Tuberculosis in Children. *Am. Rev. Tuberc.* 28, 2:251 (Aug.), 1933.

Where Public Health and Medical Practice Meet—How "ruggedly individualistic" are the present provisions for medical service? In New York State two-thirds of all hospital beds are tax supported, 15 per cent of the population receive medical care from public funds; most mental and tuberculosis, and half the venereal, cases are treated at public expense, not to mention the crippled child, the school medical services and a horde of other clinic patients.

PARRAN, T. Public Medical Care in New York State. *J.A.M.A.* 101, 5:342 (July 29), 1933.

Cockroaches May Spread Tuberculosis—The cockroach, a scavenger insect that inhabits our kitchens, crawling over and eating our food, should not be overlooked as a possible mechanical carrier of tuberculosis, says this author who fed the insects on tuberculous sputum and recovered the bacillus in the intestinal tract and feces.

READ, H. C. The Cockroach as a Possible Carrier of Tuberculosis. *Am. Rev. Tuberc.* 28, 2:267 (Aug.), 1933.

Truth in Cancer Propaganda—Urging the medical profession to assume an increasing responsibility in cancer control (to forestall more state administrative projects like that in Massachusetts), the author makes several candid statements not usually found in cancer prevention propaganda. For instance, "Probably 50 per cent of the present deaths from cancer could be prevented if treatment was undertaken in time." This is much nearer the truth than our usual "cancer is curable" sloganeering.

RECTOR, F. L. Present Day Cancer Problems. *J.A.M.A.* 101, 9:672 (Aug. 26), 1933.

Lungs Damaged With Silica Dust—Silicosis is discussed from several angles, symptoms, etiology and post-mortem and roengenographic findings, making the symposium of especial value to the industrial hygienist.

SAYERS, R. R. The Clinical Manifestations of Silicosis. *J.A.M.A.* 101, 8:580 (Aug. 19), 1933.

Inherited Cancer Susceptibility—Twenty-three years' experience, involving over 116,000 mouse autopsies, leads to this conclusion: "The genetic difference between cancer susceptibility and cancer insusceptibility involves one

gene; that is, they are unit characters . . . cancer susceptibility behaves like a recessive, insusceptibility like a dominant."

SLYE, M. The Relation of Heredity to Cancer Occurrence as Shown in Strain 73. *Am. J. Cancer* 18, 3:535 (July), 1933.

Progress in Pediatrics—Skimming over the topics discussed at the 50 annual sessions of the Pediatric Section of the A.M.A., the author reminds us how really youthful are the modern ideas of infant hygiene. The extent of the progress in so short a time should encourage all health workers.

SCHULTZ, F. W. The First Half Century of the Section of Pediatrics. *J.A.M.A.* 101, 6:417 (Aug. 5), 1933.

Tuberculosis Knowledge and Programs Questioned—How far this dark view of the tuberculosis situation

in England applies to the American scene is not known to this reviewer. But if half his criticism of present methods and present knowledge is true of us, we are in far too complacent a mood.

VARRIER-JONES, P. Tuberculosis: Why It Is Still a Problem. *J. State Med.* 41, 8:435 (August), 1933.

Breast Feeding and Future Health—Wet powder for the propagandist's guns is this conclusion: The breast-fed infant is not more resistant to disease in childhood than the artificially-fed baby, and the general health of the school child cannot be determined by the method of feeding during infancy. As one would suspect, this is British candor in all its gloomy honesty.

WILSON, J. G. Infant Feeding and Its Relation to the Health of the School Child. *Pub. Health* 46, 11:356 (Aug.), 1933.

NEWS FROM THE FIELD

WHOLE TIME HEALTH OFFICERS

ACCORDING to a directory published by the U. S. Public Health Service, in *Public Health Reports*, July 14, nearly 600 counties in the United States have health officers who devote their entire time to their official duties. In several states, groups of counties, varying from 2 to 10, are combined in districts with one health officer. Kentucky, which has 120 small counties, has 81 health officers; Alabama, with 67 counties, has 52 full-time health officers; Ohio, with 88 counties, has 44 health officers; and Tennessee, with 95 counties, has 40 health officers. In New York, only 4 counties have health service organized on a county basis, with full-time officers.

MISSOURI WATER AND SEWERAGE CONFERENCE

THE Ninth Annual Missouri Water and Sewerage Conference was held on September 22 and 23, in Jefferson City, Mo. The Missouri Public Health Association, A.P.H.A. Affiliate, met jointly with them on September 22 and 23. Among the speakers was Henry F. Vaughan, D.P.H., Commissioner of Health of Detroit, and Life Member A.P.H.A.

GORGAS MEMORIAL ESSAY CONTEST

THE Gorgas Memorial Institute of Tropical and Preventive Medicine has awarded the Maryland State prize for this year to Margaret M. Harrison, Baltimore, a student at the Roland Park Country School. The subject of the essay was "The Problem of Mosquito and Other Insect Life in Relation to Sanitation, Health and Industry."

COURSE FOR HEALTH OFFICERS

THE Albany Medical College, in coöperation with the New York State Department of Health, offers an extension course to qualify physicians for appointment as health officers of towns under 50,000 population. The course began September 1 and will continue until June.

DEATH

EDWIN W. KOPF, formerly Assistant Statistician of the Metropolitan Life Insurance Company, and F.A.P.H.A., died on August 3, at the age of 45.

PERSONALS

DR. GEORGE H. BIGELOW, F.A.P.H.A., Commissioner of Health of Massachusetts since 1925, has resigned to become Superintendent of the Massachusetts General Hospital, Boston, effective October 1. He succeeds Dr. Frederick A. Washburn, who is retiring.

DR. HENRY D. CHADWICK, tuberculosis controller of the Detroit Health Department since 1929, has been appointed Commissioner of Health of Massachusetts, to succeed Dr. Bigelow.

DR. JOHN J. PHAIR, formerly bacteriologist of the Cincinnati Department of Health, has been appointed to the staff of the International Health Division of the Rockefeller Foundation. He will be at the Research Center for Undulant Fever, Montpellier, France.

CONFERENCES

October 9-12, Sixty-second Annual Meeting of the American Public Health Association, Indianapolis, Ind.

November, Seventh American Scientific Congress, Mexico City.

November 3, Mid-year Meeting of the New York State Association of Public Health Laboratories, Albany, N. Y.

America's Contributions and Problems in Public Health*

JOHN A. FERRELL, M.D., DR.P.H., F.A.P.H.A. (Life Member)

*President of the American Public Health Association and
Associate Director of the International Health Division,
Rockefeller Foundation, New York, N. Y.*

THE term "America" as employed in my paper refers to the countries included in the American Public Health Association, namely Cuba (1902), Mexico (1891), Canada (1884), and the United States (1872). Five annual meetings have been held in Canada, two in Mexico, also a post-convention meeting, and two in Cuba. Canada has supplied five presidents, Mexico two, and Cuba one. The United States, being most centrally located, has furnished the remaining meeting places and presidents. The sixty-second annual session of the Association is being held in Indianapolis. It is the third meeting held in this city.

The first was held in 1882 and the second in 1900. That beloved Canadian, Dr. Peter H. Bryce, who founded the Ontario Department of Health and rendered other valuable services to the cause of public health, presided at the meeting in 1900. It was a historic occasion because Dr. Walter Reed then presented a paper

entitled "The Etiology of Yellow Fever. A Preliminary Note," in which he convincingly established the fact that the mosquito transmits the disease. Thus the way was opened for the rational control procedures that proved to be effective in Havana in 1902, New Orleans in 1905, and Rio de Janeiro in 1908, and made possible the construction of the Panama Canal (1904-1914). The last outbreak in the United States occurred in New Orleans in 1905 and the last in Mexico in the state of Veracruz, in 1922.

After the studies in Cuba and the control work just mentioned, a number of years elapsed before yellow fever was further studied and widely and systematically controlled. Americans, not content with its status, particularly in the equatorial zone, instituted investigative and control measures on an international scale. Mainly through the initiative of the International Health Division of the Rockefeller Foundation, and largely with its funds, these measures have continued for more than 15 years. Among the advances that have been made, I may mention that yellow

* Presidential Address delivered before the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

fever has been definitely proved to be a virus disease; a successful method of producing immunity and a reliable test of immunity have been developed; erroneous ideas as to the prevalence and distribution of yellow fever and as to the character of measures necessary for its control have been corrected; and the disease has been driven from North America and checked in a number of endemic centers of South America, and systematically studied for several years in South America and West Africa.

It is particularly fitting, therefore, that the feature of this meeting should be a session in memory of Walter Reed and his colleagues at which the historic events relating to yellow fever may be reviewed. The tributes should include Carlos J. Finlay, a Cuban physician, who advanced the theory that yellow fever is transmitted by the *stegomyia* mosquito. Dr. Finlay was president of this Association at the annual meeting held in Havana in 1904.

The indispensable reference book entitled *A Half Century of Public Health*, was published by this Association in 1921. It is one of the important contributions of Dr. Mazýck P. Ravenel that made notable his presidency of the Association in 1921. Seventeen other authorities collaborated with him in reviewing the developments of all phases of Public Health in America for the first 50 years of the Association's existence. Any attempt I might make on this occasion to cover the same ground would be futile.

Moreover, it would be impracticable for me to review all of the important individual and group contributions to the advancement of public health made by members of this Association since 1921. I shall, therefore, limit my discussion to a few of the major movements in the advancement of public health that have been distinctively American.

During the period 1850 to 1900,

the discovery of the causal organism of one disease after another was laying the foundation for scientific medicine and public health. The list of discoverers was made up mainly of Europeans. However, during the past three decades Americans have been prominent among the discoverers in etiology, serology, and other branches of science that have supplied a basis for developing sound control measures. For about 30 years after a considerable amount of knowledge as to the etiology of various diseases became available, there was apathy on both sides of the Atlantic in applying this knowledge. Finally, however, the movement got under way in America. The early steps were characterized by the establishment of boards of health (Massachusetts 1869; California and Virginia 1871; District of Columbia 1870). New York City's Department of Health was established in 1866 and by 1873 there were 134 cities which had some form of health service.

However, bacteriology did not generally afford a foundation for sound, scientific control procedures until the beginning of the present century, although New York City established a vaccine laboratory in 1874, Providence a diagnostic laboratory in 1888, and New York City a laboratory for diagnosing tuberculosis in 1893 and diphtheria in 1895. The production of antitoxin in the New York City laboratory in 1895 led to the first real check of a diphtheria rate which for years had been steadily rising. A drop of 33 per cent in the death rate in one year from diphtheria in New York City was an event of historic significance. From 1900 on America has steadily gained ground as a leader among the nations in the application of knowledge to the control of disease.

Through its effort at popular education of the masses in matters of hygiene and public health, America again has ex-

cited the interest and respect of health authorities of other countries. The official health agencies have established their educational divisions which have utilized the printed pages of magazines, newspapers, bulletins, and leaflets. The radio has been extensively employed. School teachers have been instructed. Courses in hygiene have been given in colléges, high schools, and grammar schools. Manufacturers and merchants have used labels and advertisements to capitalize the popular interest in health practices. The health officer, nurse, and inspector have carried the gospel of health to the home, the school, and the clinic. This movement in many localities has been stimulated and even initiated by nonofficial health organizations. Many of the European health officials visiting in the United States and Canada have been deeply impressed by the extent to which information about hygiene and public health has been disseminated among the masses. In popularizing public health knowledge this Association and its membership have made an important contribution.

Another American contribution to public health progress has been the private or unofficial health agency. In the United States alone there are probably over 100 of these agencies operating on a nation-wide basis. Most of them have a special interest or problem, which may be a single disease, as is the case with the National Tuberculosis Association, or a group of diseases, as in the program of the American Social Hygiene Association; or a particular age group, as the American Child Health Association. There are national organizations for the conservation of vision, for the promotion of mental hygiene, and for many similar objectives. These organizations have state and local branches.

Again, there are foundations either operating in the health field or supply-

ing funds for such work to other, usually governmental, health organizations. Certain ones do both. In connection with our foundations and other philanthropies, I might state here that large gifts of money for the advancement of all phases of public health were first made by Americans.

These various unofficial agencies have coöperated with the official agencies by supplying some of the funds for special activities, such as research, demonstrations, and training. They have encouraged the employment of professional personnel, the enactment of progressive legislation, and provision of increased health appropriations. When they have inaugurated new services, they have been glad, as a rule, to have the governmental organizations assume as quickly as possible complete administrative and financial responsibility for the maintenance and expansion of the work. Many of the projects were experimental in character and could not in the beginning have been financed with public funds. Thus the official health organizations have been stimulated, aided, and enlarged by these private agencies, and many advances in knowledge and practice have been developed much sooner than would have been possible had the official agencies been working alone.

Although the influence of the voluntary health agencies in the advancement of public health in North America has been great, a question has arisen as to whether their existence may not at times have afforded too great a feeling of safety, thus delaying appropriations for the official agencies and retarding their growth. The reverse opinion is commonly held in public health circles, but no one will deny that there may have been instances when a personally ambitious employee of a private agency may unwittingly or unwisely have worked in competition with the official organizations, but such conduct cer-

tainly would not have the approval of a recognized national, unofficial, health association.

America has contributed the university school of public health. Certain universities, colleges, and medical schools had previously offered courses in preventive medicine and public health. But we are referring to definite schools with faculties concentrating on the field of public health and with courses and teaching organized entirely from the public health point of view. In this class may be mentioned the School of Public Health of Harvard-Technology, which admitted its first class in 1914 and operated through the school year 1920. Johns Hopkins University School of Hygiene and Public Health admitted its first class in 1918. This was followed by the Harvard School of Public Health in 1922 and the University of Toronto School of Hygiene in 1927. Other schools or institutes of public health have since appeared in various countries. In establishing schools of public health on a plane corresponding with other professional schools, such as medicine, law, and engineering, America has definitely advanced the cause of public health.

In developing a fruitful method of study, Dr. Charles V. Chapin made a notable contribution to the advancement of knowledge and to its application which is a credit to America. During the long period in which he supervised health work in Providence, incidental to the effective conduct of routine activities, he carried on studies regarding the efficacy of measures for dealing with infectious diseases and introduced new practices based on new knowledge. He was the first to discontinue the ineffective and expensive practice of terminal disinfection and to direct health measures against persons rather than things. I have singled him out because he introduced a scientific method of appraisal which has enabled

all competent health officers systematically to improve the quality of their services.

For the health protection of its population America in general provides a safe supply of water and milk. In all populous centers and even in towns of from 1,000 to 5,000 population, the water supply is chlorinated and otherwise treated to make it safe. In all cities and larger towns milk is obtained from tuberculin-tested cows and is pasteurized. Its production and distribution are made to conform to the standards recommended by this Association. The same standards of safety are enforced on the common carriers and in other interstate traffic.

The difference between the bacilli of bovine and human tuberculosis was discovered in 1896 and 1898 and the transmissibility of bovine tuberculosis to man was discovered in 1902, both discoveries being made by Americans. Subsequently systematic control measures have contributed greatly toward diminishing bovine tuberculosis in America and toward making our milk supply safe. Health officers, sanitary engineers, bacteriologists, chemists, and veterinarians have all shared in these notable achievements. There are few places in the world where the traveler on train or boat, and in hotels and restaurants can eat and drink with as much safety against enteric and other diseases as in Canada and the United States. The chlorination of water and the pasteurization of milk are among the distinct advances in health practice which were first extensively applied in America.

The sanitary engineer has become an indispensable part of all well-rounded health organizations. Degrees in sanitary engineering have been awarded for many years by university schools of engineering which have organized courses designed to equip the sanitary engineer for the wide range of activi-

ties in his field: Practically every state, province, and city is now employing in its health department one or more graduate sanitary engineers. The engineer functions mainly in the field of environmental sanitation. In designing, building, supervising, or passing upon plants for purification of water and for the sanitary disposal of sewage; in matters of drainage, housing, dairying, and ventilation, he plays a very important rôle. He has many achievements to his credit and his work in America has been observed with interest by health authorities from other quarters of the globe. Sanitary engineers have their own society and through their own section are active in the work of this Association.

Public health nursing, which has become a vital factor in the conduct of public health work, is also essentially an American movement. Its influence in the public health field is fairly recent, but the growth has been rapid. Already public health nurses far outnumber any other class of health personnel in the field services of official and voluntary health agencies. The range of health activities in which they participate is extremely broad, and the quality of the service which they render is rising steadily.

The leadership in the public health nursing movement has been aggressive. Competent supervisors who direct and teach the field nurses have served to increase efficiency. Foremost among the achievements has been the establishment of persistently rising eligibility standards. University courses in public health nursing have been established, and the number of students taking the courses has steadily increased. Public health nurses have their own organization and journal. Through the section on public health nursing they share in the activities of this Association. In the development and extensive utilization of the public health nurse in the

health field, America has been a pioneer.

The important movement toward the establishment of local health service during the past two decades has been of American origin. After the new era for applying modern knowledge to the conservation of human health was well under way in the urban areas, attention was turned to the balance of the country which embraced the towns, villages, and sparsely-settled areas.

Between 1910 and 1915 the warfare against hookworm disease, typhoid fever, and other filth-borne diseases led logically to a movement to supply non-urban areas with creditable full-time health services, usually in the shape of full-time county health units. As was the case in urban organizations, the health officer, nurse, and sanitary inspector conducted the field activities. Except for a few of the stronger county organizations serving both urban and rural areas, the technical experts for laboratory, sanitary engineering, epidemiological and other services have been supplied to the local organizations by the state health departments which frequently likewise furnished administrative and financial coöperation. This movement has steadily gained ground until it now embraces nearly 20 per cent of the counties and 35 per cent of the non-urban population of the United States. In Canada and Mexico the movement has also made striking headway, which will be reported at this convention in the Health Officers Section by health officials from each of these countries. Its logical extension to a basis of adequacy will occupy the public health forces for many years to come.

In seeking to make health work a full-time, professional occupation for all classes of health workers—administrative and technical—the American Public Health Association and the American universities have set a high standard. In 1922 the Association definitely de-

cided that it was to be an organization of professional health workers and not merely a popular health association with a large part of its membership composed of persons not actually engaged in or even indirectly identified with health work. Since that time a Committee on Fellowship and Membership and another on Training and Personnel have furthered the movement for professional standards. The Committee on Training and Personnel encouraged the unification of public health courses and degrees and published a directory of professional health workers. A year ago the committee was reorganized, its name changed to the Committee on Professional Education, and its scope broadened. Among the new lines of activity which the committee contemplates adding to the existing program is the promotion of state and national eligibility standards in regard to training and experience for the positions in health organizations.

In legally requiring a diploma or certificate in public health for its medical officers of health, Great Britain has taken the lead, but in many countries health service is regarded as a part-time occupation for which special training is not usually required. In America the full-time principle has been established in national as well as in progressive state, city, and county health services, and the percentage of health workers who have taken special training for their duties is steadily increasing. Although the progress thus far made must be regarded as an important contribution, I shall later on in this paper have to list the completion of this task as one of America's important problems in public health.

Among the contributions of this Association, its standard methods take a high place. First came a standard method for the differentiation of bacteria, adopted in 1898. Next came the

standard methods for the examination of water and sewage. Then followed standard methods for the examination of milk in 1910, of air at about the same date, for the pasteurization of milk in 1920, and finally, through the Committee on Administrative Practice, standard methods or forms for the survey and appraisal of state, city, and county health organizations.

Through the efforts of members of this Association, there has been published by the U. S. Public Health Service during the past decade a survey of the health departments of the 100 largest cities of the United States, a survey of the state and provincial departments of health, and other publications which afford the health executives guidance in modern methods of organization, administration, and practice.

Each standard method has been prepared by the most expert talent available in the membership of the Association. Each has embraced the newest and most reliable information on advanced practice to be found anywhere in the world. From time to time as new knowledge and experience warranted, each standard method has been revised and brought up to date. In this way the Association has supplied the health workers in its membership, and indeed those of the world, with sound, reliable methods for carrying on their work. The contribution of Standard Methods by this Association has been of fundamental importance in the advancement of public health.

The American Public Health Association embraces every important administrative and scientific subject closely related to hygiene and public health. The scope of its activities has greatly expanded during the 62 years of its existence. Knowledge of bacteriology reached a point in 1899 which warranted the formation of a section, which concerned itself with bacteriology

and chemistry. Later this became the Laboratory Section.

Prior to the formation of sections, the meetings as a rule were made up of general sessions. The subjects of the papers to a large extent reflected the particular interests uppermost at the time in public health circles. In the early period before the mode of spread of diseases was established, attention was too often directed to things rather than to persons. Odors, such as that of sewer gas, for example, that now would be classed merely as nuisances, were of deep concern. An epidemic of cholera, yellow fever, or plague naturally caused much excitement and confusion.

The special interests of groups in each division of the health field led gradually to the formation of other sections until, as you have no doubt noted from our program, there are now 10 sections. In order to cover the present wide range of health subjects of vital interest, there is a program for each section, and besides there are general sessions for subjects too broad or too urgent to be left to a single section. The development of such an organization for the advancement of public health on a broad and comprehensive scale is in itself an important contribution to the cause of public health.

The Chairman of the Executive Board will present at this convention a detailed report of the past year's work of the administrative and clerical staffs of the Association, and of the status of membership, finances, and activities of the committees. Beyond casual references, it will not be necessary or feasible for me to dwell upon these topics. Moreover, as this brief presentation of twelve of the major movements in the advancement of public health in America has practically consumed the time at my disposal, I regret I cannot mention many notable contributions to public health that have been made by individual members, committees, or

agencies affiliated with this Association. I must not, however, close this paper without calling to your attention a few of the most vital problems which challenge the best efforts of this American Association.

The restoration of health appropriations and salaries, at least to the pre-depression status, and the reëmployment of qualified personnel now unemployed are urgent problems. Losses in funds for public health and in personnel that had occurred before the close of 1932 were distressing but the climax of the depression with its panic and hysteria was not reached until the early part of 1933. Then in at least five-sixths of the states and provinces legislatures convened and often the slashing of appropriations for all purposes was carried on indiscriminately. Although reductions for health services seldom, if ever, exceeded those for other governmental purposes, and in many cases were much less, some states, nevertheless, were left with a bare skeleton of the essentials of an adequate health service. To omit measures for the protection of health at a time when government in all its branches is having to appropriate stupendous sums for emergency relief is extremely illogical. It is the result of fear or panic and not of sound reasoning. The extent of the reduction in health appropriations varies widely. In a few states and cities it has not exceeded 10-15 per cent, but in many others it has been as much as 60-75 per cent. Now that a basis for calm consideration of corrective measures seems to have returned, the public health forces should inaugurate a campaign calculated to lead taxpayers and their representatives on appropriating bodies at least to put the public health status back to where it was prior to the depression.

In spite of the progress already made, the professionalization of public health personnel remains a vital problem for

America. The extent to which routine, administrative, and investigative problems can be handled by competent, professional workers will determine to a large degree the progress to be made by the health forces. The excellent committee assigned to this problem hopes to give guidance to the public and particularly to boards of health and executives as to suitable eligibility standards for personnel. Moreover, it seeks to be helpful to colleges and universities in laying out courses for the various types of service, and to aid those desiring to take special training. With the necessity for professional training recognized in all circles, and with a reserve of qualified personnel available so that any excuse for employing untrained persons is removed, the future advancement and efficiency of health service should be assured.

Another problem to which the Association has definitely committed itself is the enlargement of knowledge and the perfecting of technical methods. A major committee on research and standards is already functioning. It seeks to stimulate research by individuals, groups, and agencies, to keep the standard methods of the Association up to date, and to promote the development of other standard methods as occasion warrants. The acquisition of new knowledge, the supplementing and rounding-out of present knowledge, and the dissemination of the knowledge we already have for the use and guidance of health organizations constitute a problem of the first magnitude, which should engage all resources that can be enlisted.

The wider and more intensive application of knowledge already available is a major task confronting the health forces. It involves the development of health organizations, the securing of appropriations and legislation, the formulation of programs, and the conduct of field operations.

The work must be productive and efficiently carried on if the health authorities are to be guided and if the confidence of the taxpayer is to be held. In this field of administrative practice the Association already has at work a large committee of authorities and a full-time staff. The work, which has been curtailed because of a reduction in income, includes nevertheless many admirable achievements, among which may be mentioned the health conservation contests for cities and the surveys of many health departments of states, cities, and counties. To carry forward effectively this work in the field of public health administration is a task to which the Association, individuals, and corporations may well give aid.

The publications of the Association constitute the tangible consideration returned to members for their dues. They are the historical record of the administrative, investigative, and lifesaving activities of American health forces. They are the media through which the world can learn of and benefit from American developments in public health. Shortage of funds has prevented the publication of many valuable manuscripts. To enlarge these publications, to make them more adequately supply up-to-date information to the membership of all 10 sections, is a problem which the Association must meet. The item of funds presents a difficult problem. If a large part of the membership dues could be applied to the cost of publications, the matter would be simple. In order to do this, new sources of funds for financing other expenses will have to be found. The Committee on Meetings and Publications, in the face of a serious, financial handicap, has been remarkably successful in holding excellent meetings and in issuing an authoritative and useful *Journal*.

The membership and fellowship of the Association should be enlarged and

the qualification standards for membership and fellowship should be maintained. The fifth major committee, that on Fellowship and Membership, is struggling with this problem. It passes upon eligibility for each class of membership and endeavors to bring into the Association all professional health workers who are eligible. This committee has worked with diligence and intelligence and yet within the past year there has been a falling-off in membership. The following record shows the losses of the past year:

| | <i>Members</i> | <i>Fellows</i> | <i>Miscellaneous</i> | <i>Total</i> |
|------------------------|----------------|----------------|----------------------|--------------|
| August 1, 1932 | 3,503 | 857 | 355 | 4,715 |
| August 1, 1933 | 3,159 | 847 | 299 | 4,305 |
| Decrease in number | 344 | 10 | 56 | 410 |
| Decrease in percentage | 9.8 | 1.1 | 10.7 | 8.6 |

When, however, we consider the drastic depression, the curtailment of health appropriations, the reduction of salaries (which even before the depression were quite meager), and the actual unemployment of qualified workers, the situation in regard to membership in the Association is gratifying. With the gradual elimination of the untrained political appointees, and those serving on a part-time basis, whose chief interests are in other fields, I believe the Association's membership will embrace nearly all health workers who can qualify for membership.

The final problem to which I wish to invite your attention relates to adequate financing of the important activities of the American Public Health Association. With fellowship and membership limited to professional health workers, and with due consideration for the extremely small salaries in the health field, it is obviously impossible for the members, through dues, to finance all the work which the Association should carry on. The need of an endowment to cover at least a part of the Association's legitimate operating expenses has been discussed from time to time at the meetings of the Governing Council and the Executive Board. The task is still ahead of us. Although the present time may not be auspicious for actually raising an endowment, plans for one should be formulated and systematically carried forward until the objective is attained.

Of the seven important problems presented to the forces of which this Association is composed, the most acute is the one which relates to the early restoration of health appropriations and the reemployment of trained workers so that the notable gains in the field of public health which were made before the depression may be held and systematic progress may again be resumed.

Committee on Professional Education

THE following tables similar to those published in previous years present the data concerning students registered in schools of public health, and the public health degrees granted in the calendar year 1933.

COLLEGE ENROLLMENT IN PUBLIC HEALTH COURSES

The number of students enrolled, and Public Health Degrees conferred in the year 1933 in courses requiring at least 1 year of residence, by American and Canadian Colleges, is shown in Table I.

Italian Mutual Benefit Funds in Elementary Schools

A RECENT Italian decree gives effect to a law passed in 1929, establishing mutual benefit funds in the elementary schools throughout the country. Membership in the funds is compulsory for teachers and optional for pupils. The funds are intended to pay for medical care in case of illness and also for preventive measures, such as periodic physical examinations, open-air schools, school clinics, ultra-violet ray treatments, rest homes, vacation colonies, and school lunches. The decree requires that the school children be given instruction in the rules of personal hygiene and the principles of social insurance.

The dues are to be 10 lire annually; in exceptional cases they may be re-

duced to 6 lire. The dues for poor children may be paid by child welfare agencies. Part of the amount paid by each pupil is transferred to the invalidity and old age insurance fund, membership in which is compulsory for nearly all wage earners in Italy, and is credited to the pupil when he reaches the age of 20 and becomes subject to the compulsory insurance. In the case of persons not subject to old age insurance the money is placed to their credit in a Government savings bank.

For the administration of the law there will be established a "National Office of School Mutual Funds," with provincial and municipal branches.—*Ministero dell' Educazion Nazionale, Bolletino Ufficiale*, Rome, No. 14, 1933.

The Work of Walter Reed and His Associates of the Medical Department of the United States Army*

MAJOR GENERAL ROBERT U. PATTERSON

The Surgeon General, United States Army, Washington, D. C.

YELLOW fever is a disease of great interest to medical officers, not only on account of its military importance, but because of the epochal work in its control that has been done by officers of the Medical Corps of our Army. That fine old military surgeon and signer of the Declaration of Independence, Benjamin Rush, a Physician General in our Revolutionary Army, wrote in 1793 an account of his work in fighting the epidemic of yellow fever in his native Philadelphia which even today is unapproached for its realism. The part that he played in this epidemic was an important one, and if he had never done anything else, would have earned him a place among pioneers in preventive medicine.

In 1820 Surgeon's Mate Merrill of the 8th U. S. Infantry, outlined a new treatment for the disease, which, while perhaps not in keeping with modern clinical methods, at least had the merit of giving great relief to the sufferers in comparison with the extensive venesection and massive doses of purgatives that had been used up to that time.

When Carlos J. Finlay of Cuba stated his theory of the insect transmission of yellow fever in 1881, a real step forward was made, and his chief,

that distinguished scientist, Surgeon General Sternberg, realizing the desirability of special training in methods of research, sent Major Walter Reed to Johns Hopkins to study pathology under Welch.

During his tour of duty in Baltimore Reed made an important contribution to the pathology of the liver in typhoid fever. In April, 1899, he showed that *B. icteroides* (Sanarelli) was really a variant of *B. cholerae* suis (hog cholera), and if found in yellow fever existed only as a secondary invader. Following the Spanish-American War, in which there were more than 20,000 cases of typhoid fever, though battle casualties numbered only 350, a board of officers was appointed to study the cause of the epidemics. The board consisted of Major Walter Reed, Major Victor C. Vaughan, and Major Edward O. Shakespeare. There is an army saying that boards are long, narrow, and wooden, but this one was not of that character, for its findings have been of inestimable value by contributing to our knowledge of means for the preservation of the public health.

As is well known, the board found that more than 90 per cent of the volunteer regiments developed the disease within 8 weeks after going to camp; that typhoid fever is disseminated by the transference of excreta of infected individuals to the alimentary tracts of

* Delivered at the Special Memorial Session to Dr. Walter Reed and his Associates on the Yellow Fever Commission at the Sixty-second Annual Meeting of the American Public Health Association in Indianapolis, Ind., October 11, 1933.

others; that camp pollution was a more prominent causal agent in this instance than contaminated water supplies; that the disease was largely spread by flies and the hands of human carriers. Contrast for a moment the conditions which prevailed in the World War, when thanks to prophylaxis and improved sanitation, instead of the half million cases of typhoid fever which would have occurred had the rates of the Spanish-American War period prevailed, there were only 1,572 out of more than 4,000,000 men who served with the colors.

In 1900 Walter Reed was detailed as the head of what is probably the greatest of all army scientific boards. It was to pursue "scientific investigations of acute infectious disasters in the Island of Cuba," and "to give special attention to questions relating to the etiology and prevention of yellow fever." The latter disease was still thought by many to be caused by the so-called *Bacillus icteroides* of Sanarelli. Sternberg's selection of Reed for this important duty is an indication of his appreciation of his abilities. Sternberg's own great contribution to our knowledge of yellow fever was his refutation of the mistakes of other workers, and the indication that the causative microorganism was not to be found by ordinary bacteriological methods.

Reed went to Cuba in June, 1900, accompanied by his assistant, Major James Carroll. The other two members of the commission were already there, Assistant Surgeon Aristides Agramonte and Dr. Jesse W. Lazear, who had made special studies of the disease at Johns Hopkins and in Italy with Sanarelli.

An intimate friend of Reed's tells us that at the first meeting of the commission in August, 1900, four interlinking facts were considered. First, was Ronald Ross's announcement in July, 1898, of the discovery of the transmission of malaria by mosquitoes.

Second, there was the thorough cleaning which the American administration had given to the city of Havana, without in any way improving the yellow fever situation, thus apparently eliminating the question of its being a filth disease like typhoid fever. Third, there was the publication by Dr. Henry R. Carter of the U. S. Public Health Service in May, 1900, of his excellent epidemiological observations on the disease, observations which in the light of Ross's work pointed toward insect transmission. And finally there was the widely accepted belief in Havana that yellow fever was transmitted by the bite of a special mosquito. Dr. Carlos J. Finlay, a native of the West Indies, though born of Scottish and French parents, had for 20 years (*i.e.*, since 1881) argued upon epidemiological grounds that yellow fever was transmitted by the common household mosquito.

The first important contribution of the board was to demonstrate that the blood (during life) of 18 well marked cases of yellow fever (4 of them fatal) did not show the presence of the so-called *B. icteroides* of Sanarelli. Nor did cultures from the blood and viscera after death in these cases yield *B. icteroides* nor any growth or organism. In most instances nearly all cultures were negative. This finally disposed of *B. icteroides* as a causative factor in yellow fever.

At the very outset of their work Reed was called to the United States by the death of Major Shakespeare, and he had to rescue the records of the typhoid board. By the time he got back to Cuba a month later, Major Carroll and Private Dean of the Cavalry (known in the records as XY) were convalescent from experimental yellow fever, and Lazear was dead. Though not generally known, Lazear's case was also experimental.

These experimental cases occurred

just as the board was all but ready to reject Finlay's theory, for nine times they had failed to convey the disease by mosquito bites. The reason is now clear to us though then unsuspected by them. The disease was not so transmitted either because of failure to allow the mosquito to bite the ill person sufficiently early in the disease to acquire the infective agent, or a failure to keep the mosquito sufficiently long after it had ingested blood from a case, before permitting it to bite the experimental subject, so that the virus did not have the opportunity to undergo the necessary development within its body to become capable of transmitting the disease.

The experiments of the Reed commission are graphically described after the manner of a detective story by Professor Turner and Miss Hallock. In seeking the hidden criminal, the producer of the dreaded "Yellow Jack," the master detective and his assistants had presented to them six clues. The first clue was that most accounts of yellow fever mentioned the presence of mosquitoes in numbers. Thus the "suspect" was at the scene of the crime. The second clue was that the epidemics started in low wet regions or near the docks. As the mosquito breeds in water, here was another ground for suspicion. The third clue was that in high, dry parts of a city the disease was not contagious. Though people from the low-lying sections fled to the higher parts of a city, and might come down with yellow fever after arriving there, the disease did not spread to other people in the new neighborhood. Thus our detectives realized that the disease must be carried in some other way than directly from one person to another. Other detectives had realized this, but most of them jumped to the conclusion that this could only indicate that the disease must be present in the *air* of certain districts and not others. The

fourth clue seemed to strengthen the idea that the disease was air-borne. It had been noticed that it spread in the direction of the prevailing wind. As the mosquito is a great lover of home, it never travels far except when carried along by the wind, or a ship. The fifth clue lay in the observation that yellow fever flourished in hot weather, but disappeared with frost. Until our sleuths suspected the mosquito, this clue was lost on the detectives because they concluded merely that heat was a common exciting cause of the disorder. The sixth clue, one which was not discovered without careful study, was that for 15 days after a patient had come down with yellow fever his house was not infected, for people could come and go without getting the disease. But after 15 days any non-immune who would go there would take the disease in from 1 to 6 days. Reed suspected that the deadly microorganisms of yellow fever were, during this 15-day period, hidden away within the body of the villain of the play, the mosquito. This villain had a bad reputation, and had long been suspected, but it was not easy to prove the suspicion to be true.

In every well ordered detective story it is necessary not only to prove the villain guilty, but the other suspects must be proved to be innocent. In 1900 it was accepted by almost everyone that yellow fever was carried by *fomites*, that is, excretions of yellow fever patients on clothing, bedding, etc. Much valuable property was destroyed in this belief. Volunteers, under Reed's directions, slept in a poorly ventilated room, specially constructed and heated to 90° to simulate the conditions in the hold of a vessel in the tropics, making their beds with piles of sheets, pillow-slips, blankets, etc., which had been contaminated by yellow fever patients. For 20 nights three non-immune volunteers slept in this room, but none of them developed yellow fever. The ex-

periment was repeated later on two occasions, some individuals actually sleeping in the soiled nightclothes of yellow fever patients, without these volunteers contracting the disease. The fomites had been cleared of suspicion of the crime. Seven individuals in three groups submitted themselves to this experiment, which was loathsome both to sight and smell, to say nothing of their belief that they might contract the disease.

Thus we have the background and preliminary experiments of Reed and his coworkers. Animals not being susceptible, human beings must be used. The three volunteers, Carroll, Dean, and Lazear submitted to the experiment, and all came down with yellow fever, as has been said.

Further human experiment was indicated, but to do this, even though men volunteered, required the approval of higher authority. Fortunately at that time the Governor of Cuba was a great man who held at the same time two commissions. He was a major general of volunteers, and he was a captain of the Medical Corps of the Regular Army, therefore with a knowledge and appreciation of the importance of the experiments proposed. So to Leonard Wood went Walter Reed to receive his approval and promise of moral and pecuniary support. The approval of the Surgeon General was also necessary; so Reed again went to the United States.

Curiously enough, and it is of particular interest to us at this time, another commission had been working for over a year in Cuba and had decided that Sanarelli's *Bacillus icteroides* was the cause of the disease. The French Academy of Medicine had already accepted Sanarelli's organism, and the other commission sought to make its report to the American Public Health Association at its meeting right here in Indianapolis. Had the American Public Health Association likewise gone on

record as believing the *Bacillus icteroides* to be the cause of yellow fever, Reed would have indeed had a hard time to continue his investigations in Cuba. So he went post-haste to Indianapolis, and in a fiery debate routed the advocates of Sanarelli's bacillus.

In 3 weeks Reed was back in Cuba and, with funds provided by General Wood, constructed Camp Lazear, 6 miles from Havana and at a distance from all known sources of infections. Agramonte bred and infected the mosquitoes for the Commission, and all was ready except the men who should face the dreaded experiment. Two young Americans came forward and volunteered. They knew well the risk that they ran, but they also knew the vast importance to humanity of the question at issue. Their names are: John J. Moran, Field Clerk at Headquarters, and Private John R. Kissinger, Hospital Corps. Moran was first to be bitten, but Kissinger was first to be taken ill. Their act was brave and noble, and they did it without heroics or desire of reward. Later with the American volunteers were certain Spaniards who endured the test for a reward of gold and the promise of immunity from further attacks. The financial reward, however, was not sufficient to discount the courage of each American and Spaniard who received a monetary honorarium.

The brave conduct of the volunteers was recognized at the time by men of science, though the general public knew little about it. Their deed was such as to merit the award of the Medal of Honor, our highest military decoration, given only for bravery in the face of the enemy "above and beyond the call of duty." Certainly their acts measure up to this high standard, for the enemy that they faced was far more deadly than any visible enemy armed with rifle or other man made weapon.

The Secretary of War, Mr. Root, in his report of 1902, urged that this work receive merited recognition. He said:

The brilliant character of this scientific achievement, its inestimable value to mankind, the saving of thousands of lives, and the deliverance of the Atlantic seacoast from constant apprehension, demand special recognition from the Government of the United States.

But nearly 30 years rolled around before proper recognition was accorded them. By the Act of February 28, 1929, Congress directed that a Roll of Honor appear annually in the Army Register, and on this roll the names of these brave men should appear. A gold medal was also to be presented to each, or to the representatives of those who had died. It may not be amiss to cite you these honored names:

MEMBERS OF THE BOARD

Major Walter Reed, born in Virginia
Major James Carroll, born in England
Dr. Jesse W. Lazear, born in Maryland
Dr. Aristides Agramonte, born in Cuba

INOCULATED WITH YELLOW FEVER In alphabetical order:

Private John H. Andrus, born in Pennsylvania

Mr. John R. Bullard, born in Massachusetts

Private A. W. Covington, born in North Carolina

Private William H. Dean, born in Ohio

Private Wallace Forbes, born in Illinois

Private Levi E. Folk, born in South Carolina

Private P. Hamann, born in Germany

Private James F. Hanberry, born in South Carolina

Private Warren G. Jernegan, born in Florida

Private John R. Kissinger, born in Ohio

Mr. John J. Moran, born in Ohio

Private William Olson, born in Wisconsin

Private Charles G. Sonntag, born in South Carolina

Private Clyde L. West, born in Georgia

Folk, Jernegan, and Hanberry of this group had previously undergone the experiment of sleeping with fomites in the house I have already described before they submitted to inoculation by the bite of infected mosquitoes.

SLEPT IN INFECTED BEDDING

Dr. R. P. Cooke, A.A. Surgeon, born in Virginia

Private Thomas M. England, born in Ohio

Private James Hildebrand, born in Georgia

Private Edward Weatherwaks, born in New Jersey

Of Reed, General Wood said:

I know of no other man of this side of the world who has done so much for humanity as Dr. Reed. His discovery results in the saving of more lives annually than were lost in the Cuban War, and saves the commercial interests of the world a greater financial loss each year than the cost of the Cuban War. . . . Future generations will appreciate fully the value of Dr. Reed's services.

And President Eliot, of Harvard, in admitting Reed to an honorary degree, expressed himself in somewhat the same terms.

The task of eradicating yellow fever from Havana fell to Major William Crawford Gorgas, later Surgeon General of the Army. Gorgas was appointed chief sanitary officer of Havana on February 10, 1900. Under General Wood's orders he instituted the measures now practised everywhere in combating mosquito-borne diseases. He screened yellow fever patients, destroyed mosquitoes, etc., and in 3 months Havana was freed from the disease for the first time in 150 years.

The success of Gorgas in Havana led naturally to his being put in charge of similar work in the newly acquired Canal Zone in 1904. Here what had been a notorious plague spot of disease, the "White Man's Grave," as it was called, was converted into one of the healthiest communities in existence. Gorgas continued the methods which had proved so successful in Havana. In the face of much stupid opposition at first, Gorgas never hesitated in attaining his objective, that of making the isthmus free from yellow fever, and with other diseases under control, before the operations on the canal were commenced. While the elimination of

other diseases was no less important than that of yellow fever, this malady comes first in the minds of the general public. Under the French occupation it was a byword that every tie laid on the Panama Railway cost a life. From 1881 to 1889 the French lost more than 22,000 laborers by death, an annual rate of 240 per 1,000. One station on the old Panama Railway was called "Matachin," from the Spanish words *matar* (kill) and *Chino* (Chinaman), because 1,000 imported Chinese coolies at this point died off in 6 months, as did also 1,000 from the West Coast of Africa.

When the United States took charge of Panama the death rate was 40 per 1,000. A yellow fever epidemic raged from July, 1904, to December, 1905. In less than a year Gorgas had eradicated it entirely, and there has not been a single case of the disease there since May, 1906.

In one of his reports Gorgas said:

When the Canal shall have been finished it can be shown that sanitation cost about \$365,000 per year. For a population of 150,000, this means an expenditure of about 1 cent per capita per day, and this sum is well within the means of any tropical country.

Elsewhere he says:

I do not believe that posterity will consider the commercial and physical success of the Canal the greatest good it has conferred upon mankind. I hope that as time passes our descendants will see that the greatest good the Canal has brought has been the opportunity it gave for demonstration that the white man could live and work in the tropics, and maintain his health at as high a point as he can, doing the same work, in the temperate zone. That this has been demonstrated none can gainsay.

In 1906 during the period of our second intervention in Cuba, Major (now Brigadier General, retired) Jefferson R. Kean, a medical officer who had already been commended for his work in helping the Reed Yellow Fever Board, and curiously enough the first yellow

fever patient that his friend Reed had ever seen, was placed on duty by President Taft as Sanitary Adviser to the Provisional Government of Cuba. This position he held throughout the entire period of occupation (1906-1909), and during this time he extinguished yellow fever, which had reinvaded the island during the first Cuban republic, no doubt partly owing to the great increase in the non-immune population, and it had spread all over the island. In 1900, when yellow fever had been extinguished in Havana, it disappeared from the entire island.

During the remainder of his life, even while he was Surgeon General of the Army, Gorgas was frequently called to distant parts of the tropical world to give advice and assistance. After his retirement from active duty, after having served as Surgeon General through the World War, he was on his way to South Africa on work for the International Health Board, when, delayed in Europe by the award of many honors, he died suddenly in London, having been knighted on his deathbed by King George V. As Colonel Ashburn said, "He was a varray parfit gentil knyght."

The preventive measures used by Reed and Gorgas have been, and are being put into effect in many tropical lands. In his recently published report on *Twenty-five Years of American Medical Activity in the Isthmus of Panama*, a work received with enthusiasm in Britain, France, and elsewhere, Colonel Weston P. Chamberlain, Health Officer of the canal, says:

By far the larger part of the morbidity and mortality formerly attributed to tropical climates was due, not to climate *per se*, but to isolation, nostalgia, venereal disease, alcoholic excess, poor municipal conditions, and, most important of all, to infection with specific parasites whose invasion is now entirely preventable. . . .

Commenting on which, Sir William Horrocks remarks: "This may justly

be regarded as a triumph of preventive medicine."

It is a great pleasure to me to know that 4 of these brave men who submitted their bodies to the bite of infected yellow fever mosquitoes (*Aedes Egypti*), or to inoculation directly with the blood of yellow fever patients in these conclusive experiments of Reed and his coworkers, are living and present at this banquet this evening. It will be an honor to meet them face to face, and be able to greet them. It was my great privilege as a junior officer of the Medical Corps of the Army to be a member of the class which graduated from the Army Medical School in 1902. This was the last class to complete the entire course under the direct teaching of this great benefactor of humanity, Walter Reed. He died, as you know, November 23, 1902, shortly after the opening of the session 1902-1903 of the Army Medical School. He was a born teacher. His command of clear and concise language, and his ability to impart his knowledge to others I have never seen excelled, if equalled. How happy we students were to be able to call him friend. While he was a member of the Medical Corps of the Army, on which he shed such undying luster, by his accomplishments he belongs, as we in the Medical Corps of the Army are always proud to feel and never forget, to the whole American medical profession. The inspiration of his work and those who labored with him will remain with us forever!

In closing, I have some personal recollections connected with the eradication of yellow fever from the island of Cuba during the second occupation. In the years following Reed's and his coworkers' discovery and its practical application by Gorgas, the first Cuban Republic had been established. As you know, yellow fever again was reintroduced into Cuba. You will recall that at the time of the second intervention

one of the problems which the provisional government had to face and solve was the presence of yellow fever in the island. It was my good fortune to serve during the second intervention, 1906 to 1909, as a member of the Army of Cuban Pacification. Through the courtesy of General Kean, then a major, and as previously stated the sanitary adviser for the provisional government, I met Dr. Carlos J. Finlay, Dr. Juan Guiteras, and Dr. Aristides Agramonte, who were known as the Yellow Fever Board. One of their duties was to see all cases of yellow fever occurring in Havana and to make a final diagnosis in any case of doubt. Owing to the kindness of the members of the board I had an opportunity to see practically all cases of yellow fever in the Beneficentia and the Las Animas Hospitals in Havana until the disease was controlled. I was intensely interested in having this opportunity to see closely this interesting disease. It is a matter of great satisfaction to me to recall that I had this opportunity and the privilege of knowing these three distinguished men, particularly Dr. Finlay who, though he did not prove his theory, was the one who was always convinced that the mosquito was the vector. A few months ago at a dinner given in a private home in Washington, I had the pleasure of meeting the son of Dr. Finlay, who is also a doctor and a specialist in ophthalmology. At the time he had literally just "escaped" from Cuba as he told me. On account of his interest in the students and his connection with the University of Havana, he had been seized by the Machado government last spring and put in prison for a period of some months without any charges being preferred, or being given a chance to face his accusers. Some time after he was released he had excellent reasons to think that his life was in imminent danger. He was forced to come to the

United States. It was interesting to meet the son of a great man who also has inherited from his father much personal charm and professional ability.

I trust that our good friends in the Island of Cuba will soon be able to adjust their difficulties and restore once more in that beautiful country a stable

government which will insure the prosperity and happiness of all their people.

I hope that the American Public Health Association on this occasion will send a special message to the faithful wife of Walter Reed who was his companion during his years of service, and who still survives him.

A Symbol

THE Yule log—symbol of Christmas through the ages. On the great holiday the lord of the manor threw wide the doors, and misery and squalor were forgotten in the cheer of the boar's head and wassail.

Customs change, but the Christmas spirit is ageless. Today millions express it by the purchase of Christmas Seals—the penny stickers that fight

tuberculosis—still the greatest public health problem. Your pennies will help pay for free clinics, nursing service, preventoria, tuberculin testing, X-rays, rehabilitation and other important work such as medical and social research. *Buy Christmas Seals.*—The National, State and Local Tuberculosis Associations of the United States.

The Story of the Epidemic of Encephalitis in St. Louis*

JOSEPH F. BREDECK, D.P.H.
Health Commissioner, St. Louis, Mo.

THE story of the epidemic of encephalitis in St. Louis and its vicinity is a very interesting one. Climatic conditions in the area involved were unusual for the three summer months—June, July and August. According to the official Weather Bureau records, the rainfall in St. Louis County for these months was the lowest since 1837, when the first official records began. For the City of St. Louis, the rainfall was the lowest in its history, except for a very small portion of the city which, during a single cloudburst, put the official record somewhat higher. The drainage and sewage problem in St. Louis County was favorable to the breeding of unusually large numbers of mosquitoes in areas commonly infested. In addition, the odors emanating from these open sewage channels were pronounced throughout the unusually dry summer season. In passing, it is of interest to know that there was an epidemic of rabies in St. Louis which began in March of this year.

The first information concerning the epidemic of encephalitis reached the Health Division of St. Louis August 8, 1933, when the superintendent of the Isolation Hospital notified the Health Division that 16 cases of an unusual type of encephalitis were admitted from the St. Louis County Hospital. On

August 9 these cases were examined by a member of the Health Division together with staff members of the Isolation Hospital. The histories, physical examination, and other facts obtained were discussed by the members of the Health Division, and immediate steps were taken to advise the medical profession and the laity of the epidemic. It was important that such knowledge reach the public as well as the medical profession, and the newspapers of St. Louis were very coöperative in promulgating all necessary information.

On August 10 still more cases came in from the County, and it was quite obvious then that the City of St. Louis could not escape the epidemic. Plans for field investigation were formulated and started on the same day, on the County cases, since there were then no cases reported in the City of St. Louis proper.

On August 12 a telegram was received from the Surgeon-General of the U. S. Public Health Service offering us all assistance we might need, and we wired back requesting an epidemiologist. Dr. James P. Leake, Senior Surgeon, U. S. Public Health Service arrived on the morning of August 14. Up to this date we still had no cases reported in St. Louis, so that all of our investigations were concentrated out in the County.

On August 12 it was felt that if we were to get anywhere in the study of this epidemic, we must have the co-

* Presented at a Special Session of the American Public Health Association on Epidemic Encephalitis (under the auspices of the Health Officers Section) at the Sixty-second Annual Meeting in Indianapolis, Ind., on October 10, 1933.

operation of all the health officers in St. Louis and surrounding territory. Letters were sent out to all of these officers inviting them to a meeting in the Health Commissioner's office in St. Louis on August 14. At this meeting a uniform questionnaire was proposed and general plans for handling the epidemic were discussed. On August 17, the Metropolitan Health Council was formed, composed of all health officers in St. Louis County, St. Louis proper and those on the East side, in St. Clair and Madison Counties, in Illinois. The Metropolitan Health Council was to be a coöperative body, to meet at call of the secretary for the handling of emergencies and the exchange of ideas on public health matters. Rules and regulations for handling the cases of epidemic encephalitis were suggested and adopted.

Early field investigations led us to believe that we were dealing with a disease which was similar in its spread to poliomyelitis. The cases were widely scattered, occurring in the suburban areas of the County. It was apparent very early that rarely more than one member of a family was affected, and that the upper age groups were involved more than younger individuals.

It was important also to decide on the hospital program to be inaugurated. The Isolation Hospital it was evident would not be able to handle all the cases, so that the throwing open of all the hospitals in St. Louis for the care of these patients was an urgent matter. As the field investigations were so strongly in favor of the disease not being readily communicable from one member of the family to another, we felt it would be safe to handle these cases in the general hospitals provided sections of the hospitals were set aside for their care and where the routine isolation could be enforced as with any other communicable disease. This was done by sending a notice to all super-

intendents of hospitals and had their complete and immediate coöperation.

It became manifest early that the diagnosis was delayed for several days in many patients who had nothing more than fever. The early cases also showed the importance of lumbar puncture as a diagnostic procedure. Since it was of the utmost importance to stress lumbar puncture, we deemed that the hospital was the only satisfactory place where this could be done with the minimum amount of risk. While it is true that in some homes lumbar punctures could have been done, in most instances it was not satisfactory. Besides, the clinical symptoms and complications that arose made it almost impossible to care for these patients in the average home without a day and night nurse. Bladder symptoms requiring catheterization, and patients with delirium often requiring restraint would be handicapped by home treatment. Therefore, hospitalization of all cases was urged, and over 95 per cent of the cases throughout the epidemic were handled in hospitals. Hospitalization further gave an opportunity for more accurate clinical studies and laboratory studies than could have been made at home.

Now that the epidemic is practically over the wisdom of such a procedure is more apparent than ever. Today we can gather uniform clinical and laboratory data from the hospitals so that a complete study and analysis of the epidemic can be made with less amount of error and with more satisfactory types of record.

It was important early to draw attention to the fact that all fever cases where there were no obvious signs of any disease should have a lumbar puncture. In this way we emphasized the importance of early diagnosis and the isolation of doubtful fever cases until such a time that an accurate diagnosis could be established.

Through the newspapers and members of the medical profession we were able to create a public sentiment and coöperation that was amazing. The information issued early was complete from the clinical angle so that little difficulty could be experienced in recognizing the importance of fever, headache, and other symptoms so prominent in this disease. The response was almost dramatic. The cases came in from all sources for consultations to the Health Division, and hospitalization was made routine. Hospitalization served a double purpose of establishing the diagnosis more promptly and at the same time isolating the patient. It was urged that this isolation should be maintained for at least 3 weeks from the date of onset of the disease. All the bulletins that were issued called attention to the clinical symptoms and necessity for isolation.

The reports started coming in to the City of St. Louis on August 17. Then a very curious phenomenon occurred when we started to date back the onset of the first case. Medical men commenced to think back and there was a certain amount of friendly rivalry among the profession as to having had the distinction of recognizing the first case. This led to the discovery that cases that had recovered for several weeks were not reported. When we analyzed the cases we found that the first cases in St. Louis proper were on July 30. The first case in the County was July 7.

With the importance of fever of unknown origin, a number of curious circumstances arose in which we discovered that a large number of bloods had been sent to the City Health Laboratory for Widal test for typhoid. The number of such bloods sent in was over 100 per cent higher than the year previous and this occurred during the month of July and continued throughout August. All of these bloods were

negative for typhoid. A complete analysis of these cases is not yet available, but there are suspicions that some of these were probably encephalitis cases of mild character.

With a uniform history blank for the County as well as the City a central clearing-house through the Metropolitan Health Council was established. Daily reports of cases were sent in to the secretary who had them tabulated, and mimeographed copies made and sent out to all health officers of the Council. In this way they kept in touch with the progress of the epidemic. All rules and regulations were based on the strong belief, after field investigations, that we were dealing with a virus disease transmitted through the nasal secretions. Such impressions were reached early because of the very close similarity of spread, and of the seasonal occurrence as in poliomyelitis.

In the County in the first place water was excluded because there were two separate water supplies in St. Louis County, both of which areas were equally involved in the epidemic. The milk supply of St. Louis County is largely supplied from the same dairies as those supplying the City of St. Louis. Home investigations showed no common sources of food in any of the families, so that water, milk and food were excluded early.

Before the first week elapsed numerous theories came pouring into the Health Division office and we had a revival of many of the ancient theories concerned with past epidemics. The miasmatic theory was revived in so far as many felt that the odors from sewers and open drainage channels were responsible for the epidemic. Because the term "sleeping sickness" had been applied, it was thought by less well informed people to have been transmitted by flies. By a strange coincidence a missionary and his family had visited St. Louis County who had just

returned from Africa and within 30 days the epidemic of encephalitis started. The purchase of certain foreign species of animals for the Zoo were also thought to have brought the disease to the City. These, of course, were dismissed without any serious consideration and are mentioned because they are but a few of the many fanciful suggestions that a health officer receives.

Then, as the cases came in with no contact history, the carrier mode of spread became quite important. With the large number of mosquitoes in the areas involved naturally this theory became quite prominent in the minds of many "well-informed" people. However, it never appealed very strongly to the Health Division that mosquitoes played an important rôle in the spread of the disease. With the infection so widely spread and the prevalence of mosquitoes so obvious, they had to be investigated thoroughly. As the result, the Public Health Service men together with the man from the Army Medical School carried on this work to attempt to solve the problem. Up to this time there has been no evidence accumulated to show that mosquitoes have any part to play in the transmission of this disease. While these experiments have not yet been completed, we naturally hold an open mind as to the results.

It was important early to centralize all the laboratory work, particularly from the research angle. All of the pathological material had to be gathered together for animal inoculations since the spinal punctures and brain cultures were negative. With negative cultures by competent laboratory investigators in several hospitals, it was felt that we were on the way to establishing it as a virus disease.

Various animals were selected for the inoculations of brain tissue and other body fluids. Before the susceptible animal was found one of the laboratory

investigators found inclusion bodies in the kidney which lent further support to the virus theory of disease. Following closely upon this, monkeys that had been inoculated with brain substance from autopsy material, developed fever and clinical symptoms of encephalitis as seen in man. The microscopic pictures were not unlike those found in human cases. This was very encouraging indeed, and up to this time the monkey inoculations have progressed and the virus has been carried on through three or four series of monkeys. It is the hope and ambition of those engaged in this research that the virus will be maintained and adapted to this species of monkey so that further valuable data may be accumulated. The difficulties of adapting the virus are many. It is too early to state at this time whether such adaptability will be complete or not.

Even the laboratory workers had many suggestions offered them as to how they should proceed. But we have been very fortunate in St. Louis in having two great medical schools who have so admirably coöperated in this research work. Washington University was selected to carry on the particular animal inoculations together with the Public Health Service men, because they had suitable animals, laboratories, and a personnel particularly interested in virus diseases. It was the most expedient place to carry on the work without any loss of time, and a place in which the Service men might establish their headquarters for field as well as laboratory investigations.

Centralization of authority in the Metropolitan Health Council for handling the entire epidemic was a very important step. The personnel of both universities, the hospitals, and the health officers have coöperated to the fullest extent. Their example of unity of purpose might well be emulated elsewhere. With conflicting views and sug-

gestions coming in from all directions the Metropolitan Health Council has stood firmly on the principles that no regulations should be made without careful consideration of the facts obtained. Theories have their place when based on facts. The best professional minds were mobilized locally with the coöperation of the State Health Department and the Public Health Service. No words of mine could express the gratitude, particularly toward the Public Health Service, that is felt by the local authorities in St. Louis and surrounding areas. Their steadying influence has served to concentrate effort and regulations.

As time went on, the opening of the schools became a problem in the minds of many and the St. Louis Health Division, and the Metropolitan Health Council took a very definite stand that the schools should be opened without any restrictions. Health officers are very often tempted by public sentiment and even by professional men to close schools when anything unusual happens. There was no real basis whatsoever for the closing of the schools. The Health Division of St. Louis felt very strongly that this was a time for education of the public and took the stand that schools should open. Public opinion should be created and not merely accepted. There were many who doubted the wisdom of this recommendation, but almost simultaneous with the opening of the schools the epidemic reached its peak and has continued to subside ever since. Others felt that because of the dryness of the season and the odors emanating from many sewers that the Fire Department should be called out to flush sewers. Another miasmatic revival. No water was wasted and the epidemic subsided.

Most of the aggravation we had to contend with came from without the City where newspapers not in contact with the local situation tremendously

exaggerated the picture. People were afraid to come to St. Louis to transact even urgent business. Parents were afraid to send their children back to schools and colleges. Yet they had been advised by local, state and federal authorities that business matters could be carried on as usual in St. Louis. Up to this date we have had no reports come to us that lead us to believe that the epidemic was spread elsewhere by any persons going through St. Louis.

During the course of the epidemic, the Metropolitan Health Council appreciated the necessity of making official reports of the research investigations and these were to be made in writing by the Research Committee so appointed and given out by the Council alone. Up to this time the Committee has reported only facts as they have come forth with animal inoculations. As the epidemic progressed the Metropolitan Health Council further has appointed a committee for follow-up work every 3 months for the next year and every 6 months for the second year. The purpose of this was to determine the nature and severity of the after-effects that may have resulted from this disease. Another committee has been appointed for publication so that authoritative facts may be forthcoming from this epidemic. In this way we hope to contribute something of value to others who may be confronted with this same problem in the future.

The Metropolitan Health Council has felt deep responsibility locally as well as nationally in the handling of this epidemic. We have been fortunate, indeed, in having the splendid assistance of the U. S. Public Health Service and others outside of St. Louis in attempting to solve some of the difficult problems involved. We have tried to demonstrate modern public health methods in handling this epidemic while conflicting opinions arose. One of the most important precepts govern-

ing the regulations that were issued was to emphasize first principles of handling any communicable disease: "early diagnosis, hospitalization, and isolation of all fever cases until an accurate diagnosis could be established." The practical handling of the problem could not wait for laboratory confirmation. Many questions arose that might involve months or even years to solve. The soundest principles that we felt were justified were in the belief that this was a virus disease and spread by human carriers and mild cases. Because of the rarity with which more than one member of a family was involved, it was not even deemed advisable to quarantine members of the family. The Health Division did not want to impress anyone with the idea that it was doing more than it was possible to do.

The public was thoroughly informed daily as to the actual facts in the epidemic, and the reasons why certain precautions were taken and why many

other procedures were not advocated.

That the measures of early diagnosis, hospitalization and isolation were efficient can be measured only by the fact that 95 per cent of the reported cases were hospitalized. How successful in checking the disease this was, is a matter of speculation. There is no actual method that we can apply in determining the efficiency of such measures. They are, however, those that have been recognized in the handling of all communicable diseases. Our greatest consolation was in the fact that we did not issue regulations which were not based on sound public health practice. Until more fundamental knowledge is forthcoming concerning the true etiology, mode of spread, or specific remedies for this disease nothing could be advocated further.

The epidemic has now disappeared to the point where there are only a few sporadic cases. We have witnessed to date an epidemic of 1,065 cases with 197 deaths.

Epidemiology of Encephalitis*

With Special Reference to the 1933 Epidemic

JAMES P. LEAKE, M.D.

Senior Surgeon, U. S. Public Health Service, Washington, D. C.

THE identity or non-identity of the encephalitis prevalent during August and September of this year in St. Louis and elsewhere, with ordinary lethargic or epidemic encephalitis, is an open question.

Assuming for the present that they are two different diseases, it may be

useful to compare them epidemiologically with poliomyelitis. In spite of the similarity of the St. Louis disease to poliomyelitis as to seasonal epidemic occurrence and minute histological changes (apart from the preponderant selective localization of poliomyelitic lesions in the anterior gray matter of the spinal medulla), they cannot be considered as due to the same virus. Though showing a limited amount of variation from epidemic to epidemic,

* Presented at a Special Session of the American Public Health Association on Epidemic Encephalitis (under the auspices of the Health Officers Section) at the Sixty-second Annual Meeting in Indianapolis, Ind., on October 10, 1933.

poliomyelitis as a disease is not subject to such a wide variation as would be necessary to cause an entire epidemic like the recent one. Poliomyelitis has not been so difficult to transfer to animals as has the recent disease. In a limited personal survey—the result of the present investigation will of course not be available for months—two children were found to have had poliomyelitis a few years before the attack of encephalitis, and similar cases have been mentioned this year in Kansas City and Cincinnati. Two attacks of poliomyelitis in the same person are much more uncommon than this.

Except for the higher mortality in Japan, which is always an uncertain difference, the St. Louis outbreak appears to be a counterpart of the Japanese disease which was epidemic recently in 1924 and 1929. The Japanese have differentiated this as Type B encephalitis, and it may be convenient to preserve this distinction, calling the ordinary form, described by Economo, Type A encephalitis, until immunity tests or other study justify a combination or further separation.

The course of the epidemic is shown in Table I, in cases reported by weeks for St. Louis County and St. Louis City, two mutually exclusive administrative units.

The city is $3\frac{1}{2}$ times more populous

than the county, having 840,000 people to the county's 230,000. It is evident that the epidemic began in the county, and was more intense there, the rate of cases per 100,000 being 230 for the county and 63 for the city, or 99 cases per 100,000 population for the city and county combined.

This sharply defined seasonal distribution is the same as that occurring in Japan, and is similar to that of the large epidemics of poliomyelitis, but is totally different from that of Type A encephalitis, which occurs at all seasons, but always has had its periods of highest incidence in winter and early spring. Compared with the St. Louis rate of 99 per 100,000, the rate in Kagawa province, the most severely affected in Japan, was 270 in 1924 and 51 in 1929. The area of Kagawa province is $1\frac{1}{3}$ that of St. Louis City and County and the population is $\frac{2}{3}$ as great. This is the 6th densest of the 47 provinces of Japan.

Multiple cases in the same family, and connected cases, have occurred in the St. Louis area in about the same proportion as with Type A encephalitis, and somewhat less frequently than in a poliomyelitis epidemic of similar intensity and population density. It might be expected that in an epidemic preponderantly of older people there would be fewer multiple cases in the same family than in epidemics chiefly affecting the young.

The relative frequency of mild or abortive cases is uncertain. Histories of possible cases of this sort have been obtained, but their identity with this disease remains inconclusive in many instances. It is believed that more mild cases have been reported and counted in the total in the St. Louis epidemic than is usual in epidemics of encephalitis.

Data regarding the incubation period are important. Considering only cases where absence from or entrance into the epidemic area occurred just prior

TABLE I

REPORTED CASES OF ENCEPHALITIS BY WEEKS
IN ST. LOUIS COUNTY AND ST. LOUIS CITY

| Week ending | St. Louis County | St. Louis City |
|--------------|------------------|----------------|
| August 12 | 41 | 4 |
| August 19 | 58 | 15 |
| August 26 | 82 | 39 |
| September 2 | 106 | 103 |
| September 9 | 86 | 106 |
| September 16 | 76 | 108 |
| September 23 | 32 | 65 |
| September 30 | 20 | 49 |
| October 7 | 14 | 31 |
| October 14 | 7 | 13 |
| | <hr/> 522 | <hr/> 533 |

to onset, 7 cases indicated that the infection took place at least 4, 7, 8, 9, 11, 13, and 14 days, respectively, before the first symptoms, while 6 cases indicated that the infection took place not more than 9, 12, 14, 14, 14, and 21 days, respectively, before the first symptoms of the disease in the case becoming infected. The extreme possibilities for the incubation period in these cases would therefore be 4 and 21 days, and the necessary variation in this small group is great enough to take in incubation periods of 9 and 14 days.

No racial or sexual predilection has been shown, except a preponderance of males in the younger age groups, which is common to most diseases. There is no greater frequency in males than in females in the early adult years, such as is usual in smallpox.

As to age, the age group under 15 years comprises 23 per cent of the population in the St. Louis area, and had 13 per cent of the cases; the group 15 to 34 years old had 36 per cent of the population and 23 per cent of the cases; the group 35 to 54 had 28 per cent of the population and 29 per cent of the cases; the group 55 and over had 13 per cent of the population and 35 per cent of the cases.

An even greater preponderance in the aged characterized the two Japanese epidemics which covered the same area most intensively in 1924 and 1929, 5 years apart. A somewhat similar area was covered by the Japanese epidemics of 1912 and 1919, with a similar tendency as to age.

About 20 per cent of the cases reported in the St. Louis area have been fatal, slightly less in the county. This is in contrast to 50 per cent to 60 per cent fatality in the Japanese epidemics. It may be noted, however, that in Japan the ratio of the cases reported in the aged, to the population concerned, in percentages of the totals, is about twice that in the St. Louis area. In other

words, it seems possible that in Japan only the more serious cases tend to be reported, for both here and there the disease is much more severe and more fatal in the older age groups. A similar tendency with regard to smallpox has at times been noted in Japan, where a fatality rate of 80 per cent has been reported—much higher than is recorded elsewhere for large epidemics.

The age distribution of cases is of course very different from that observed in poliomyelitis, where the preponderance is much more marked in the opposite direction, the incidence being highest at about 5 years in metropolitan centers. The age distribution in Type A encephalitis varies with the reporter. There is no such uniform preponderance as in poliomyelitis, but usually during epidemics cases have been more frequent during the later childhood and early adult years, to about the same or to a greater extent than is true for the older age groups in Type B encephalitis.

Among the St. Louis cases, the milk supply was so various as to exclude that as a major factor in spreading the disease. The water supplies of St. Louis County and St. Louis City are entirely different. The early appearance of the epidemic in the county practically to the exclusion of the city, at once directed attention to the water, but within the county the municipality of Kirkwood has a supply drawn from the Meramec River, while St. Louis County and St. Louis City draw from the Missouri and the Mississippi Rivers above the Meramec. The Kirkwood cases were investigated and found to have used Meramec River water, and the incidence of the disease in Kirkwood was even slightly higher than in the remainder of the county.

No distinction as to economic status or occupation apparently separated the persons attacked by the disease from the remainder of the population.

The location of the cases is interest-

ing. There were 522 cases in the county, and 533 cases in the city, giving a rate per 100,000 of 230 for the county and 63 for the city. If the 28 city wards be divided into 6 groups, the eastern group, wards 2-11, bordering the Mississippi River but not the county, have an incidence rate per 100,000 of 31. The south mid-city wards, 13-16, have a rate of 46; the north mid-city wards, 18-22, 51; the two extreme northern and southern wards, 1 and 12, bordering both river and county, have a rate of 67, and the central mid-city wards, 17, 23, 25, and 26, a rate of 72. The three western wards 24, 27, and 28, bordering the county and not the river, with a population about the same as that of the other groups, have a rate of 142. Of the incorporated places in the county, the rate in University City was 200, in Clayton 177, in Richmond Heights 186, in Maplewood 236, in Webster Groves 158, in Kirkwood 284, in Glendale 480, and in Brentwood 530 per 100,000 population. Compared with these rates, Kagawa, the most thickly settled and the most heavily attacked province in Japan in both 1924 and 1929, had a rate of 270 in the former year and 51 in the latter. There are 1,000 people per square mile in Kagawa Province and 2,000 in St. Louis City and County.

This heavy incidence around, rather than in the middle of, the most densely populated area, is characteristic of the

disease this summer in Kansas City, and in other cities. It is striking, but is no different in order of magnitude, from that found in poliomyelitis. The rate in the New York City epidemic of 1916 was nearly tripled in the less thickly settled boroughs of Richmond and Queens as compared with the more metropolitan boroughs of Manhattan and the Bronx.

It is probable that even if Type B encephalitis is a different disease from Type A, it is not entirely new to this part of the country. Dr. H. D. McIntyre reported similar cases in Cincinnati in 1932 and the Illinois State Department of Health reported an outbreak of about 27 cases in Paris, a city of 9,000, in the same summer.

Cases in epidemic intensity have occurred this year in the Kansas City area, in St. Joseph, Mo., and in Louisville, Ky., but with less intensity than in the St. Louis area. In general, the prevalence has been below the 40th parallel of latitude. This geographical distribution, together with the seasonal incidence, suggests an insect carrier, and experiments are under way to test this hypothesis, but there is a similar tendency in poliomyelitis for certain latitudes to be more severely affected, and the early spread of the cases throughout the wide extended suburban area, instead of by radiation from a focus, is more characteristic of human than of insect transmission.

Types of Epidemic Encephalitis*

A Comparison of the Cases Seen in St. Louis in 1933 With Those Seen in New York City

JOSEPHINE B. NEAL, M.D.

Executive Secretary, Matheson Commission. In Charge of the Division of Infections of the Central Nervous System of the Health Department, New York, N. Y.

PHYSICIANS practising during the past two decades have had the rare opportunity of observing the reappearance and development of epidemic encephalitis. Undoubtedly this disease has occurred in epidemic form under a variety of names during the centuries, and scattered cases have been diagnosed in retrospect in the years immediately preceding the present outbreak.

So far as we can learn the first cases of this epidemic occurred in the spring of 1915 in Bucarest, Rumania, and were described as hemorrhagic encephalitis. Then in the winters of 1915 to 1917, 40 cases diagnosed as subacute encephalomyelitis developed along the Western front in France. An account of these cases was published by Cruchet and his coworkers shortly before von Economo's excellent description of the early cases in Vienna in 1917. To these cases von Economo applied the term "encephalitis lethargica," and to the end he upheld the use of this name. However, he stated that the early cases under his observation had a widely varying symptomatology, although profound somnolence was often an outstanding symptom. At present for

many reasons the term "epidemic encephalitis" is preferred. As time went on the disease spread to England, and the observations by certain English writers that lethargy, asthenia, and cranial nerve palsies constituted the typical triad of symptoms has led to many errors of omission in diagnosis.

The first cases to be diagnosed in New York City occurred in the fall of 1918, and these were largely of the meningeal type.

These statements are made not because they are in any way new, but to emphasize the widely varying symptoms that were present even in the small groups of early cases.

Attempts have been made to divide epidemic encephalitis into types, and elaborate classifications have resulted from these efforts. However, many cases could not be included in any type, and other cases in the course of the illness ran through several types. Therefore it seems inadvisable to try to classify the cases with any degree of exactness. Of course, certain broad and general descriptive terms may be retained. For example, it is logical to call cases in which the meningeal symptoms predominate "epidemic encephalitis, meningo-encephalitic type," and cases with evidence of cord involvement "epidemic encephalitis, encephalomyelitic type." Aside from these sub-divisions,

* Presented at a Special Session of the American Public Health Association on Epidemic Encephalitis (under the auspices of the Health Officers Section) at the Sixty-second Annual Meeting in Indianapolis, Ind., on October 19, 1933.

I should prefer to call all other cases simply "epidemic encephalitis."

That the acute stage of encephalitis is often undiagnosed is apparent to any one who has worked with patients in the chronic stage of the disease. Not infrequently these patients give a history of some mild febrile attack which escaped diagnosis altogether, or was called influenza. Sometimes careful questioning elicits the fact that this febrile attack was accompanied by transient blurring of vision, or diplopia, or by delirium, or by unusual drowsiness, and it becomes evident that a diagnosis of epidemic encephalitis should have been made at the time. In other instances, however, the initial illness was evidently so mild that it seems quite likely that no definite diagnosis could have been made. Occasionally patients are seen who experienced a period of diplopia or other visual disturbance without any other symptom and who remained ambulatory. Later, symptoms of the chronic stage developed.

It is therefore evident that we are dealing with an infecting agent—probably a virus—which may invade the body, producing at first only mild systemic symptoms or affecting only a small local area in the brain without systemic symptoms. Or it may go on—accompanying general symptoms of greater or less severity—to invade any part of the central nervous system. In some of these respects it resembles the action of the virus of poliomyelitis. But the similarity between the two stops sharply at this point. The localizing tendency of the virus of poliomyelitis is much more sharply defined than that of the virus of encephalitis, and the period of its activity is limited—with very rare exceptions—to a few days. Poliomyelitis never presents the highly varied and bizarre clinical picture that often appears in epidemic encephalitis. Moreover the virus of encephalitis in

many instances has a tendency to lie dormant for months or many years, later flaring up abruptly into a true exacerbation—which may or may not resemble the original acute attack—or beginning to smolder, slowly but relentlessly, producing the symptoms of what we term the chronic stage of the disease.

It has often been noted that in the various waves of epidemic encephalitis there have been different outstanding groups of symptoms. This does not connote in any way that different causative agents have been at work. Different epidemics of poliomyelitis have shown quite wide variations in symptomatology. The same is true of influenza, in regard to which we can speak less confidently on account of our lack of knowledge of the etiological agent.

Mention must be made of the Australian X-disease in 1917 and 1918. It occurred in hot, dry seasons. There was a case fatality of 70 per cent. Nearly 50 per cent of the cases were less than 5 years of age. The symptoms—convulsions, muscular rigidity, coma, mental confusion, and high fever—in no way suggested poliomyelitis, nor did the fact that 2 of 35 recovered cases had some form of mental disorders resulting from the disease. In a third case typical Parkinsonism had developed 21 months after the initial attack. Indeed the symptoms and the residuals fit in very well with a diagnosis of epidemic encephalitis. On the other hand, the lesions in the brain were considered by Flexner to be more characteristic of poliomyelitis. But are the lesions of the two diseases sufficiently different to base the diagnosis on these grounds alone? I have always thought that this outbreak may very well have been epidemic encephalitis.

Summer encephalitis, so-called, in Japan presents interesting problems. Some Japanese writers incline to the opinion that this is a disease entity dif-

ferent from epidemic encephalitis. Others believe it is a special form of the disease and they call it "epidemic encephalitis—Type B." Epidemics of greater or less extent have apparently occurred in Japan from time to time during the hot seasons since 1871. The most severe outbreak was in 1924, when nearly 7,000 cases were reported, with a case fatality of about 60 per cent. The greatest incidence and the heaviest mortality were in the older age groups, in patients more than 60 years of age. Kaneko and Aoki believe that this condition is not so infrequent in young people as the statistics indicate, but that it runs a milder course and is more frequently undiagnosed.

The clinical picture of summer encephalitis is characterized by a more acute onset, more marked meningeal symptoms, a greater tendency to delirium and hyperkinetic phenomena or to coma and greater muscular rigidity, than is the so-called winter encephalitis or Type A. Paralysis of the eye muscles are rare in Type B and common in Type A, while paralysis of the muscles of the head and extremities are more frequently found in Type B than in Type A. Kaneko and Aoki state, however, that there are numerous transition cases, and that the seasonal distribution does not always hold—a disease picture very similar to Type B may occur in the colder seasons and one resembling Type A in the summer. Moreover, Parkinsonism, which the authors do not believe follows Type B, is frequently observed in the districts infected with Type B. It is stated that Type B may be followed by neurasthenic symptoms, headache, sleeplessness, irritability, and, particularly in children, changes in mentality and personality. All these manifestations are now considered characteristic of the chronic stage of epidemic encephalitis. Furthermore in 1919, in different regions where Type B appeared in small

epidemics in the summer, cases of Type A were observed the following winter.

The pathological lesions of the two types appear to differ only as to location and degree and not absolutely in these respects. Indeed Flexner expressed the opinion that the pathological changes closely resembled those found in the European and American cases of epidemic encephalitis.

As more careful and comprehensive studies have been made of the central nervous system in cases of epidemic encephalitis, it has been found that the lesions in most cases are scattered throughout the entire brain and in some instances involve the spinal cord. Consequently there is a swing away from the original conception that localization of lesions in the basal ganglia was a characteristic of the pathology of the disease.

When one considers all these points, it seems reasonable to believe that summer encephalitis in Japan is, in fact, epidemic encephalitis of the meningo-encephalitic type.

My personal experience with epidemic encephalitis dates from the fall of 1918. During that time 11 cases were seen by our division. None of these presented the triad of symptoms described by the English physicians. Nine showed indications of meningeal involvement, and 10 changes in the sensorium. There was no disturbance of vision. In 3 cases there were changes in the reaction of the pupils. In 1 instance there was limitation of the motion of the eyes. Cranial nerve palsies, not involving the eye muscles, were noted in 3 instances and other paralysis once. Changes in the reflexes occurred in 8 cases but no pathological reflexes were noted.

As time went on the preponderance of different symptoms varied. In general, meningeal symptoms have been present in roughly 50 per cent of our cases each year since 1918. Changes in

the sensorium, drowsiness, stupor, irritability, delirium, maniacal states, in all possible combinations and progressing from one to another in the same patient, have constantly been found in a large percentage of patients up to 75 or 80 per cent. Disturbances of vision began to appear in 1919 and were present in about 18 per cent of the cases. They have never occurred in more than about a third of the patients in any year. These disturbances of vision include blindness, usually temporary, blurring, diplopia, and rarely a curious condition in which objects seem very small, as if the patient was looking through a concave lens.

Changes in the pupillary reactions, limitations of the motion of the eyes, and other cranial nerve paralyses have been present in from a half to three-quarters of our patients. Changes in the superficial and deep reflexes have occurred in about these same proportions. One of the most constant changes has been diminution or loss of the abdominal reflex. The changes in the deep reflexes have included increase, decrease, and inequality. Pathological reflexes have been noted in a fifth or less of the cases. An interesting fact about both changes in reflexes and pathological reflexes has been their variability from day to day or even from hour to hour. Indeed this rapid change is characteristic of most of the signs and symptoms in epidemic encephalitis.

Paralysis or paresis of muscles, other than those supplied by the cranial nerves, were most frequently noted in 1921, in 1923, and thereafter in about 10 to 25 per cent of cases. These paralyses were more often of the spastic than the flaccid type. In some instances they resembled a hemiplegia following a cerebral accident. Sensory changes have been noted in a small number of cases, usually not more than 10 per cent each year.

We saw no cases with convulsions in 1918. Since that time they have occurred in varying numbers of cases up to perhaps 20 per cent in some years.

Tremors or twitchings of groups of muscles began to be a not infrequent symptom in 1919, being present in a fifth or less of the patients.

Changes in muscle tone, spasticity or the lead pipe rigidity were noted in a small number of cases each year since 1918. Catatonia was occasionally observed.

Speech difficulties of various types were occasionally noted. A small number of patients complained of tinnitus, and in two or three instances there was some degree of deafness. Other patients apparently had an increased acuity of hearing and were greatly distressed by ordinary sounds.

It is, of course, impossible to refer to the many unusual symptom that occurred.

The onset was slow in somewhat more than half the cases. Headache was an almost constant feature, as was also some type of fever. Gastrointestinal disturbances were common, of which obstinate constipation was most frequent.

Looking back over the past 15 years, I should say that we have seen in New York a fair representation of epidemic encephalitis in its multitudinous form. I am convinced that only a small percentage of cases are diagnosed in the acute stage. Some no doubt are too mild to admit of a definite diagnosis. But many physicians seem to be so impressed with the importance in diagnosis of that dramatic triad—lethargy, asthenia and cranial nerve palsies—that they are unwilling to diagnose cases in which this does not occur. While these symptoms are almost conclusive evidence of epidemic encephalitis, it is my opinion that they are found in a relatively small percentage of cases.

We have never had a real epidemic

of encephalitis in New York City, and—except for those few early cases in 1918 of the meningo-encephalitic type—we have dealt with all kinds of types. But always there has been a fair representation of the meningo-encephalitic type.

In consequence I was not surprised to see the patients in St. Louis conforming so strictly to that type. The acute onset, the headache, the fever, the stiffness of the neck and spine, the Kernig, the absence of abdominal reflexes, the occasional changes in the deep reflexes, the low incidence of ocular disturbances or cranial nerve palsies, the drowsiness or stupor, the less frequent restlessness or delirium, the obstinate constipation, the short course in patients without other complications, were all characteristic of this type of the disease. Indeed this form is usually considered the most benign, both in its acute stage and in regard to the probability of later developments.

The points about the epidemic that did seem to me unusual were, that it occurred in hot weather, that the age incidence was so high, and that there were so many colored patients. Among

more than 1,200 patients observed by either our division of acute infections of the central nervous system or by the Matheson Commission, there have been no more than 5 or 6 negroes. It may well be that they were better diagnosed during the epidemic in St. Louis.

It may be of interest to note—though it has no particular bearing on the title of this paper—that I have found in our records 12 instances in which patients had both poliomyelitis and encephalitis. In 9, poliomyelitis developed first and in 3 encephalitis was followed by poliomyelitis.

It is evident that during the past 18 years there has been a world-wide incidence of unusual involvements of the central nervous system. We are forced to one of two hypotheses—(1) that during this time there has been an infecting agent attacking any part of the central nervous system and giving rise to highly varied clinical pictures. (2) That there have been several infecting agents, equally widespread and giving rise to much the same pathological reactions in the central nervous system. Of these the first hypothesis seems the more logical.

DISCUSSION

RALPH S. MUCKENFUSS, M.D.

*Assistant Professor of Medicine, School of Medicine, Washington University
St. Louis, Mo.*

WHEN the laboratory investigation of the epidemic of encephalitis in St. Louis was centralized in a committee by the Metropolitan Health Council, the work was organized into three branches. One division undertook the study of the pathology of the disease; a second division studied clinical laboratory data; and a third division investigated etiology. These

were not sharp divisions of personnel, but were the three lines along which studies were to be pursued.

In carrying out this plan, a letter was sent to the hospitals in the metropolitan area suggesting a minimum routine for the laboratory study of cases, and requesting that members of the committee be notified of autopsies so that material for study could be collected. The num-

ber of cases made available in this way made it possible to exercise more care in the selection of material for experimental work.

It seemed obvious that a study of the etiology of this disease should not be undertaken in too great a spirit of optimism, but that the work should be planned in such a manner that negative results would be significant. Accordingly blood, spinal fluid, and autopsy material were carefully cultured, with negative results except for rare instances in which the small numbers and variety of the bacteria recovered justified considering them either secondary invaders or contaminants.

The failure to demonstrate any cultivable organism that appeared to be of etiological significance led to the belief that the causative agent was probably a filterable virus. Since herpes virus has been drawn into discussion

most frequently in connection with studies on the etiology of encephalitis, an effort was made to isolate it by the inoculation of a number of rabbits and some cebus monkeys. The uniformly negative results of these inoculations would seem to justify the conclusion that herpes virus does not play an etiological rôle in the St. Louis epidemic.

Animals of a wide variety have been inoculated in an attempt to isolate a virus of etiological significance. Any detailed report of the experimental results at this time would be premature, except to say that some of the findings are encouraging. A number of rhesus monkeys have shown elevated temperatures accompanied by weakness, incoördination and tremors. Pathological examination of these animals showed changes consistent with human encephalitis. This work has not progressed far enough to permit definite interpretation.

THEODORE C. HEMPELMANN, M.D.

St. Louis, Mo.

IT has been my privilege to see a large number of the cases of encephalitis in St. Louis from the very outset of the epidemic down to the present time. The larger part of these was seen at the St. Louis Isolation Hospital, where, to date, we have had 318 cases. Of these, 68 have died, making a mortality rate of about 21 per cent, and 197 have been discharged, with 53 still remaining in the hospital.

When the first cases were brought to the hospital, before we were aware of the presence of an epidemic, we commented on the striking similarity, in certain respects, between these patients and those we saw 3 and 4 years before during an extensive measles epidemic when there was a surprisingly large number of cases of post-infectious encephalitis following measles and other infectious diseases. In both there were

the abrupt onset, headache, vomiting, drowsiness, and mental confusion with frequent aphasia and tremors, all of which were followed in most instances by rapid improvement, usually within a period of 10 days to 2 weeks. It soon became apparent, however, that this type of encephalitis was entirely different from the others, and moreover, was present in epidemic form. The commonest symptoms of the disease, as we have observed it, have been a rather abrupt onset, with high fever (104° – 105°), headache, and stiff neck, although rigidity of the neck has occasionally been absent even in cases of considerable severity. At this time, too, some degree of nausea is apt to be present, and within a few hours many patients develop mental confusion and disorientation, aphasia, and tremors of the hands, tongue and lips. Drowsiness

was common, but coma was rarely so deep that the patient could not be aroused sufficiently to comply with simple requests. In some instances, however, instead of drowsiness, there was hyperirritability and hyperexcitation. Delirium occurred, but was rarely violent or noisy except in the case of alcoholics.

One of the most interesting points of the epidemic, however, was the very small number of patients who showed ocular manifestations. When these occurred, perhaps the commonest was slight blurring of vision for a day or two at the onset of the disease, and even less frequently transient double vision from involvement of the ocular muscles. I can recall no instance of well defined ptosis in the entire series of cases observed. Mild degrees of exophthalmos were noticed in a number of instances, but it was difficult to determine whether these had been present but unnoticed before the illness, or were the direct result of the encephalitis. In one case, however, a woman had been operated upon some months previously because of an exophthalmic goiter, but some degree of exophthalmos and persisted. Following the sudden onset of encephalitis, there was a rapid increase in the exophthalmos, so that the eyes seemed protruded entirely out of the orbits, making it impossible to close the eyelids. This patient died within a few days of the onset, but no autopsy was obtained.

Among the other less frequently observed symptoms were vertigo early in the disease, disturbances of hearing (noises and partial deafness), ataxia of the upper and lower extremities, and paralysis, the latter usually represented by a facial weakness, or spastic paralysis of one or more extremities.

In practically all cases, lumbar puncture revealed a marked increase in the spinal fluid cell count, and often surprisingly high, so that counts of 300-

500 were occasionally seen, and in one instance 1,100 cells per cu. mm. Rarely the first tap revealed a normal fluid, but when repeated a day or two later the typical increase in cells was noted. The cells were predominantly lymphocytes, it being very exceptional to find much increase in the polys, although in a few cases the first tap showed 30-50 per cent polys, with subsequent punctures revealing fluid which conformed to the usual type. The spinal fluid sugar was normal or slightly elevated.

In the neurological examination, probably the most constant deviation from the normal was an absence of abdominal reflexes during the acute stage of the disease, although exceptions were found to this rule, especially in children. The Kernig was positive in the majority of cases, although occasionally slight or absent despite pronounced nuchal rigidity and high spinal fluid cell count. Pathological toe signs were found rather frequently, but apparently bore no relation to the severity of the disease. Fundus examinations in the first 60 cases revealed nothing of consequence except frequent engorgement of the retinal vessels. The pupils were usually quite small but not pin-point, and reacted to both light and accommodation. Several of our patients had a marked ataxia of the cerebellar type, but coarse or intention tremor of the hands was less frequent than one made up of finer movements.

In the uncomplicated cases of encephalitis, it has seemed to me that the temperature curve is rather characteristic. At the onset of the encephalitic symptoms the temperature is usually high, approaching 104° - 105° F., but following the peak, a step by step fall occurs, so that the normal is reached within about 6-10 days. There were occasional exceptions to this in which the febrile course was more prolonged or, less frequently, fell by crisis. Subsequent elevations usually denoted the

presence of complications. It may be of interest to mention the fact that herpes labialis was encountered in a very small percentage of cases.

Although in many cases, the first symptoms noticed were definitely of the encephalitic or meningeal type, in a number of others these were preceded by what appeared to be a definite period of invasion. In such instances there were commonly a moderate amount of fever and headache, "grippy" pains in back and limbs, chilly sensations, and often a sore throat or, less frequently, other mild upper respiratory symptoms. Photophobia and slight conjunctivitis were not infrequently seen at this stage, but real rhinitis or pronounced cough and bronchitis were very rare. Although some patients had a slight rigidity of the back or neck even at this stage, this was usually so slight as to be overlooked in the usual examination. This "period of invasion," if it may be called such, lasted as a rule from 1 to 4 days, during which time the temperature tended to become lower and the patient's malaise and general discomfort were definitely lessened. Then, with the onset of the encephalitic syndrome, there was again a marked exacerbation of the temperature, headache, stiff neck, and all the other typical symptoms.

In contrast to these two types, mild forms of the disease were encountered which were diagnosed only with the greatest difficulty. Such patients had fever and usually some headache, but lacked the tremor and mental confusion which might have given the clue to the disease. Often a very slight neck rigidity or the mere presence of fever of unknown origin prompted the lumbar puncture which revealed the charac-

teristic increase in lymphocytic cells. It seems probable that many such cases were missed entirely.

Following an illness as severe as this one, the rapidity of recovery was frequently little short of amazing. Even in cases of considerable severity, in many instances the patients had apparently returned to normal within 10 days to 2 weeks. Indeed, in the 197 cases discharged after a 3 weeks' isolation period, all but a very few seemed to have recovered completely, except for a varying amount of general weakness. This relative absence of residual effects is in striking contrast to what is usually seen in epidemic encephalitis, but whether or not sequelae will develop in the future no one would be justified in predicting. In a few instances mental confusion persisted longer than this period, and among the other symptoms which were slow in clearing up may be mentioned nervousness, irritability, and weakness of the facial muscles.

Of the 318 cases of encephalitis treated in the St. Louis Isolation Hospital up to October 9, 1933, 68 died; but only 8.8 per cent of the deaths were from uncomplicated encephalitis. Of these 68 who died, 69 per cent had broncho-pneumonia, 39 per cent nephritis, and 23½ per cent both nephritis and pneumonia. The deaths by decades are of interest and were as follows:

| | Age | Percentage Mortality |
|------------|----------------|----------------------|
| 1st decade | (0-10 yrs.) | 0.0 |
| 2nd | " (10-20 yrs.) | 2.5 |
| 3rd | " (20-30 yrs.) | 5.1 |
| 4th | " (30-40 yrs.) | 3.4 |
| 5th | " (40-50 yrs.) | 19.5 |
| 6th | " (50-60 yrs.) | 24.5 |
| 7th | " (60-70 yrs.) | 51.0 |
| 8th | " (70-80 yrs.) | 60.8 |
| 9th | " (80-90 yrs.) | 66.6 |

DISCUSSION

HOWARD ANDERSON McCORDOCK, M.D.

*Department of Pathology, Washington University School of Medicine
St. Louis, Mo.*

THE pathological lesions found in the fatal St. Louis cases have been similar to those described in previous epidemics of acute encephalitis. The only consistent abnormality apparent to the unaided eye was an intense congestion of the meningeal and intracerebral blood vessels. In addition to this vascular congestion, many of the brains from severe cases showed small hemorrhages in the meninges. Cross-sections through the fresh brain revealed congested intracerebral blood vessels, which gaped open and oozed blood. The cerebral cortex often showed a decidedly pink hue instead of the normal gray color. In some cases, the entire cortex was pink, but in others this change was patchy in distribution. This pink blotching was also seen in practically all severe cases, in the pons and basal ganglia. Small petechial hemorrhages were seen a few times, especially in the pons. The most characteristic gross lesion seemed to be the pink discoloration of the gray substance. It was also occasionally seen in the spinal cord.

Microscopical sections show essentially the same changes that have been described by different observers in previous epidemics, the three features of most importance being the vascular congestion, cellular infiltration and evidences of toxic degeneration in the nerve cells. The blood vessels and capillaries are usually markedly distended. The pink discoloration of the gray substance that was seen with the naked eye was due to capillary congestion. Small petechial hemorrhages in the brain tissue similar to those seen in

poliomyelitis are occasionally encountered. Usually, however, the hemorrhage is confined to the perivascular lymphatic space.

The cellular infiltration is of two types. Practically all cases show the typical perivascular collection of lymphocytes and other types of round cells. This lesion is especially conspicuous in the pons and basal ganglia, although in a few cases it is present also in the white substance of the cerebral hemispheres, and in the spinal cord, particularly in the cervical region. In addition to this perivascular cellular infiltration the more severe cases show small focal collections of cells scattered throughout the brain substance. Many of these foci are found in the cerebral cortex and some are situated close to the meningeal surface. They also occur in the midbrain and in the basal ganglia. These cellular foci are not situated about blood vessels, but they seem to have been attracted to areas where necrosis has occurred in the brain tissue. They resemble the glia stars described by the neuropathologists. The remains of a degenerated nerve cell can often be found at the centers of these cellular foci.

Various degenerative changes are found in the nerve cells. Although no particular region of the brain seems to be exempt from this degeneration, the brunt of the attack appears to be borne by the nerve cells in the midbrain and basal nuclei. The nuclei of the cranial nerves are not especially involved. The degenerative changes are those ordinarily observed in nerve cells, namely swelling and eccentricity of the nucleus,

chromatolysis and, in the end, neuronophagia.

Bacteria or other microscopic organisms have not been observed in the brain tissue. In severe cases the lesions in the nervous system are widespread, and are not confined to the midbrain or basal ganglia. A study of many cases gives one the impression that the process in the brain is not one that first starts in the midbrain or basal ganglia and spreads from there to the rest of the brain; but that it is a diffuse process which apparently begins simultaneously in many regions of the brain.

In severe cases, lesions are found in other organs. In the viscera the changes resemble those seen in fatal cases of septicemia and consist of

petechial hemorrhages in the serous surfaces and in the mucous membranes. There is often a hemorrhagic and edematous type of pneumonia similar to that seen in individuals dying early in the course of acute epidemic influenza. The kidney in many instances is swollen, the blood vessels are intensely congested, and, on section, the cortex shows cloudy swelling. The kidney pelvis is also congested and may show petechial hemorrhages. Microscopically the epithelium lining the convoluted tubules sometimes shows degenerative changes. Intranuclear inclusion bodies have been found in the cells of the tubular epithelium of the kidney in about one-quarter of the cases so far examined.

THOMAS M. RIVERS, M.D.

Rockefeller Institute for Medical Research, New York, N. Y.

THE epidemic in St. Louis is an excellent example of the harmonious coöperation of local physicians, local health officers, and federal authorities. The investigators have been exceedingly generous with material useful for experimentation obtained during the outbreak of encephalitis.

The facts presented indicate that the epidemic disease occurring in St. Louis is caused by an infectious agent. The question naturally arises as to what kind of an infectious agent is responsible. Infectious agents are usually classified as protozoa, fungi, bacteria, spirochetes, rickettsia, and viruses, and from previous experiences coupled with data presented at this time one is led to suspect that a virus is probably the etiological agent responsible for the epidemic under discussion.

Then comes the question—What kind of virus is inducing the disease? A word should be said regarding the kinds of viruses from which one may choose. First, we have viscerotropic virus dis-

eases as exemplified by measles and yellow fever; second, there are viscerotropic and neurotropic virus maladies as seen in canine distemper and hog cholera; finally, some viruses, *c.g.*, rabies, are entirely neurotropic. It is not absolutely essential that a disease be established in an experimental animal in order to obtain an idea about what part of the body is attacked by an infectious agent, because this fact can be ascertained by a study of the lesions produced by a disease in its natural host, and Dr. McCordock's remarks concerning pathological changes in organs other than the brain are interesting and significant. It is clear that the virus responsible for the St. Louis epidemic invades the brain, but it has not been definitely established that other organs are not also involved. In other words the virus under discussion may be an agent with viscerotropic as well as neurotropic qualities.

From the epidemiological standpoint, it is essential to ascertain, if possible,

whether the St. Louis virus is purely neurotropic, because, if it is only neurotropic, the likelihood of its appearance in the blood stream and of its transmission from person to person by means of blood-sucking insects is remote. Therefore, once the purely neurotropic qualities of a virus have been established, the epidemiologist can more or less disregard insects in his search for the modes of dissemination of the etiological agent in a population.

In spite of the fact that one cannot as yet be certain of the qualities of the virus causing the St. Louis epidemic, it seems that all of the observers are agreed that the clinical and pathological pictures presented by the cases are those of an encephalitis. There seems to be some difference of opinion, however, as to whether this outbreak is similar to that described by Economo and known as epidemic encephalitis. To make a positive statement at this time concerning the relation of the two maladies would be a mistake. Such a remark gains force when it is remembered that the tissues of the body—this is particularly true of the brain and cord—are capable of responding to injury in a limited number of ways. For instance, different viruses may cause similar clinical pictures; the viruses of poliomyelitis and rabies (Trinidad outbreak) at times produce an ascending

involvement of the cord and brain known as Landry's paralysis. Although the clinical pictures under these conditions are indistinguishable, they are, nevertheless, produced by different etiological agents. Furthermore, the same virus can and often does produce different clinical pictures in the same species of host. This fact is well exemplified by recent experiences with louping ill (a natural virus disease of sheep) in man, a host responding to the infection with a clinical picture similar to that of influenza, epidemic encephalitis, or tuberculous meningitis. Therefore, in view of the fact that one may obtain a false impression through the classification of diseases, particularly the encephalitides, based solely on clinical and pathological pictures, it seems best to wait for the results of further work on the etiology of the St. Louis encephalitis before a definite decision is reached concerning its relation to other diseases in which an inflammation of the central nervous system is a prominent if not the only demonstrable feature. Finally, I trust that I am not too optimistic when I take the remarks of Dr. Muckenfuss regarding the experimental work in animals to indicate that we may hope for a rapid clarification of the situation based on the identity of the etiological agent.

Production of Antitoxins by Means of Bacteriophage^{*}

N. W. LARKUM, PH.D.

Michigan Department of Health, Lansing, Mich.

THE theoretical basis for the clinical application of bacteriophage has been a stumbling block in the way of its widespread use and general acceptance. The idea that any biological product could eliminate an infection by dissolution of the organisms concerned without damage to the tissue cells of the host was too fantastically simple to arouse much enthusiasm among many physicians and found little more favor in the more esoteric group of those who devise and carry out experiments. Nevertheless an idea so attractive could not fail to receive attention, and so for 15 years medical literature has contained a very respectable number of articles concerning bacteriophage therapy.

Had clinical trial resulted in failure, bacteriophage no doubt long since would have been found in that limbo where rest so many so-called biologicals that were born to abbreviated lives. As report follows report in the medical journals, however, it becomes apparent that bacteriophage is being more and more extensively applied and month by month is finding greater favor. Meanwhile, the physician, the investigator, and the teacher await a development which will reconcile the reported therapeutic results with the known activities of the bacteriophagic principle.

At the moment there exist several theories concerning the mechanism of

bacteriophage therapy. By far the greatest proportion of those who use bacteriophage at all do so in the hope and expectation that the principle coming into contact with the infecting bacterium will destroy the organism and hence free the patient from infection. The bacteriophage used must be able to lyse the organism causing the infection, must come into contact with the organism, and must bring about lysis in the situation where the organism is found. All conditions predisposing against lysis, such as inoculation of repeated doses which produces an antilytic serum, must be avoided. Despite the attacks to which this theory has been subjected, attacks which render the position all but insupportable, it is upon this foundation that bacteriophage therapy today largely rests.

Opposed to this concept are those who claim that lysis is but one of the manifestations of bacteriophage action, that lysis probably seldom occurs under the condition existing in the body, and that bacteriophage therapy if of value at all, owes its success to some other activity of the principle. As one of this group, I have consistently maintained that bacteriophage was of value chiefly through its ability to lyse bacteria *in vitro*, thus putting the bacterial antigen into soluble form and hence forming a vaccine, and that bacteriophage therapy was primarily vaccine therapy. At the same time, as clearly stated in a recent paper,¹ I pointed out that there were other

^{*} Read before the Laboratory Section of the American Public Health Association, at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

activities of bacteriophage that might play a rôle in the recovery of the patient. By taking this stand it was possible to tie up bacteriophage therapy with a widely used if dubiously regarded practice, namely, vaccine therapy. As a justification for this attitude, the *Journal of the American Medical Association*, which has consistently opposed bacteriophage as a therapeutic agent, has recently acknowledged that there may be some justification for its use in the preparation of bacterial antigen.²

But while using the vaccine assumption as a means to the end of attempting to explain the apparent success of bacteriophage therapy it has always appeared that there was something resident in the bacteriophage itself of considerable significance. The observed effects in the patient following the use of bacteriophage were too dramatic, and too rapid to be explained solely on the basis of specific bacterial antigen therapy. If lysis by the bacteriophage did not occur in the patient, and it was a simple matter to demonstrate in many instances that it did not occur, some other activity must be accorded to the bacteriophage in order to account for the results. However much this may have been getting the cart before the horse with respect to the development of a new therapeutic procedure, it has had the virtue of leading to results as will appear later.

In most if not all infectious diseases the picture both clinically and pathologically is that of a more or less severe toxemia. The local lesions produced by bacteria are seldom of a serious nature, and as a rule do not occur at all until late in the disease. In typhoid fever, for example, there is little or no damage attributable to the bacillus itself until long after the patient has been seriously and critically ill. In pyelitis, the presence of colon bacilli in the kidney pelvis produces a reaction

scarcely detectable upon microscopic examination of the tissue involved, yet the patient may be seriously, even critically ill. This is certainly no new concept of the mechanism of bacterial infection, yet it is surprising how much our efforts in the treatment of bacterial infection have been directed toward getting rid of the bacterium and how little toward combating the toxin. It is perhaps significant that where success has attended the development of specific methods for the treatment of infectious diseases it has been in infections caused by organisms from which soluble toxins could be obtained and antitoxins developed. Failure to succeed in other instances has been caused by our inability to produce toxins which are incidental to the production of antitoxins.

To return again to the subject of bacteriophage, it has been apparent that the clinical use of this principle has suggested its rôle as a producer of antitoxins. Although its use in typhoid fever has been extremely limited, those who have injected typhoid bacteriophage into patients early in the disease have noted particularly the cessation of toxic symptoms. The bacteria did not disappear; in fact, the duration of the disease as measured by the persistence of the organisms in the feces was not shortened, but the patients were not sick in the accepted sense of the word. In the treatment of pyelitis and cystitis with bacteriophage, the most striking observation is the subsidence of symptoms. Bacteria remain in the urine for varying intervals following injection of bacteriophage, but the patient is clinically well. Similar observations in connection with other infections serve but to emphasize the point that the use of bacteriophage either neutralizes the toxins present or stimulates the rapid production of antitoxin.

In view of the long period over which bacteriophage has been studied it might

be expected that the apparent relationship between bacteriophage and toxin would have been investigated. As a matter of fact it was, and the results were so unanimously against antitoxic effect that the problem was regarded as solved. Very early in his work on bacteriophage, d'Herelle³ reported that when the serum of rabbits inoculated with Shiga bacteriophage was injected into other rabbits, these second animals showed increased susceptibility to Shiga toxin. Hence the conclusion was drawn that bacteriophage did not produce antitoxin. Likewise both Gratia⁴ and Hauduroy⁵ and later d'Herelle showed that rabbits injected with repeated doses of staphylococcus bacteriophage developed a hypersusceptibility to staphylococcus infection, particularly to toxic effects of such infection. Observations such as this encouraged no expectation that bacteriophage was either antitoxic or capable of producing antitoxin. Furthermore, for those organisms producing exotoxins suitable bacteriophages have not been readily obtained except in the case of Shiga dysentery where there is no simple method of evaluating the potency of the toxin *in vitro*. Hence there has been no method for direct study of the problem.

But clinical experience over a period of several years has led to skepticism regarding the development of hypersusceptibility in individuals receiving repeated inoculations of staphylococcus bacteriophage, and within the past year, with Miss Corpron⁶ I reported results exactly opposite to those of Gratia, Hauduroy and d'Herelle concerning the effects of repeated and large doses of staphylococcus bacteriophage in rabbits. Our animals developed a degree of immunity and showed especially, resistance to staphylococcus toxin. Furthermore, the work of Burnett⁷ and his co-workers, and of Dollman⁸ made available a toxin (staphylococcus) which

could be easily measured and which was produced by an organism against which a highly active bacteriophage was available. These facts together with clinical observation over several years led to an investigation of the relationship between bacteriophage and bacterial toxin.

The results of this investigation follow. Details may be found in a preliminary report recently published.⁹ Staphylococcus toxins having titers of from 1:100 to 1:500 were prepared. These titers are measured by the dilution in which toxins produce hemolysis of rabbit red blood cells in 1 per cent suspension. It should be noted that the hemolytic titer of staphylococcus toxin is closely correlated to the dermo-necrotic and lethal properties of the toxin. Hence while the hemolytic property is easily measured, conclusions based on the results are applicable to the other properties of the toxin.

Staphylococcus bacteriophage is not a toxin since it has no hemolytic power and is innocuous to rabbits. When bacteriophage is combined with staphylococcus toxin, no reduction in the hemolytic or dermo-necrotic power of the toxin is observed. Hence, bacteriophage is not itself an antitoxin. When, however, rabbits are immunized with staphylococcus bacteriophage, their serum is capable of neutralizing staphylococcus toxin with respect to both hemolytic and dermo-necrotic properties of the toxin. This antitoxin is produced rapidly and to a reasonably high titer.

These results were obtained with the stock bacteriophage such as has been used during the past 7 years by the Michigan Department of Health and distributed for use in treatment of staphylococcus infections. It contained staphylococcus antigen, metabolic products of staphylococci and the nutrient medium in which the phage was prepared in addition to the lytic prin-

ciple itself. Obviously no conclusion as to the rôle of bacteriophage in the production of staphylococcus antitoxin could be attempted unless the experiments were performed with bacteriophage free from these associated products. Staphylococcus bacteriophage was accordingly purified by the method of cataphoresis described by Kreuger and Tamada¹⁰ and rabbits were injected with the purified products. Serum from these rabbits neutralized staphylococcus toxin, thus showing that the antigenic stimulus to the production of antitoxin was the bacteriophage itself.

Having then demonstrated that staphylococcus bacteriophage is an antigen capable of producing staphylococcus antitoxin, there remains the question as to how far generalization may be based upon this discovery. It has already been pointed out that bacteriophage for *B. typhosus* and the colon bacillus when used therapeutically had the effect of abating the toxic symptoms in the patient. Streptococcus phage has the same property. It seems logical then since the problem is not yet susceptible to direct experimentation to make the tentative conclusion that all bacteriophages are capable of

producing antitoxins. In the event that this conclusion is verified there now exists the means specifically to combat most if not all known bacterial infections, prophylactically by immunizing with bacteriophage, therapeutically by injecting serums prepared by immunizing animals with bacteriophage. At the same time there is now put into our hands the means of standardizing bacteriophage products, determining adequate and reasonable dosage and studying quantitatively the results obtained in a given patient.

Peru Child Welfare Clauses in the Constitution of 1933

THE constitution promulgated in April, 1933, states that the protection of the physical, mental, and moral health of children is the primary duty of the State. The State must also safeguard the child's right to home life, education, vocational training, and assistance in case of illness or neglect. The State shall intrust these tasks to qualified technical agencies.

Primary instruction is to be com-

pulsory and free. At least one school must be established in each community with 30 children of school age; this includes farming, mining, and industrial communities. In each department at least one school for vocational education is required.

The State shall enact legislation for the care of public and personal health and for the protection of labor.—Official text of the Constitution.

The Need of an Index Statisticus*

A. W. HEDRICH, Sc.D., F.A.P.H.A.

*Associate in Biostatistics, School of Hygiene and Public Health,
Johns Hopkins University, Baltimore, Md.*

THERE is a story of a ship's cook, who accidentally dropped a silver spoon into the sea. When called to account, his defense was that the spoon wasn't lost—nothing was lost so long as one knew where it was.

Each year, there is produced in the public health and related fields, much valuable statistical information which is doomed to a rôle similar to that of the silver spoon. The difficulty is not so much with the standard table, published year after year, but mainly with the more unusual, or occasional table—a type that is often most informing.

To illustrate: In preparation for a published study, Dr. A. W. Freeman¹ in 1916 searched for tables of the case fatality of typhoid fever by age; he found only one. Fifteen years after publication, a very desirable table of this type was brought to him, which had been published in the 1908 *Annual Report* of the New York City Health Department. He had actually looked through some of the volumes of the New York reports, but the table had been published only once, and had, therefore, been missed by him.

As a second example, a search was once made in our department during practically a solid week for a certain life table which had been published in an out-of-the-way place.

It even happens that information will

be laboriously tabulated from one section of a voluminous publication, such as the decennial census report, and later it is found that the same information is present in more desirable form in another section of the same publication. Instances of such difficulties with raw material could be multiplied indefinitely.

There are a number of reasons for this state of affairs. One is, that volumes are not always indexed adequately as to statistical content; another is that there is for the statistical field no consolidated index, such as exists for certain other fields.

Indexes to individual volumes—

Turning to annual reports, we sometimes find that there is no index at all, or that the index titles are too vague. Thus, a highly important table, showing the completeness of birth reporting, may be indexed only under "R," for the title "Report of birth index clerk." Accurate and meaningful titles for tables are the first requisite to an index, and proper cross-indexing is a second. Thus a table showing *populations, deaths* and death rate from all causes, by color, sex and *economic status*, should at least be indexed under the words that have been italicized, and, in some instances, under the other headings also. It is especially important to cross-index for the more unusual variates; for this reason, economic status was stressed in the example given.

The form of index followed in U. S.

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

Mortality Reports and in the Vital Statistics Report of New York State has much to commend it for annual volumes. We find, for example, such entries as the following:

EXHIBIT I

Rabies, deaths from, 25, 99, 106; by age, 198, 223, 502; by race, 198, 220, 502; by sex, 198, 220, 502; in urban and rural districts, 166.

—, death rate, 99.

If one wishes to find rabies deaths by age, race and sex, he will look for such table on page 198 or 502, since those numbers appear under all three headings. This arrangement saves much time in referring. It would also be possible to index such tables somewhat as follows: Rabies, deaths by age-race-sex * 198, 502.

Howard W. Green has used an interesting form of reference guide which is perhaps more of a table of contents than index. An example is shown in Exhibit II.

Cumulative indexes—The usefulness of the statistical material of periodic reports can further be increased by the preparation of cumulative indexes, which might, in one way or another, be brought to date every 5 or 10 years. As an experiment, the author prepared such an index of *U. S. Mortality Reports* from 1900 to 1929, which revealed interesting information, whose existence had not been suspected. After completion of this index, it was dis-

* The hyphens are suggested to indicate cross-tabulation. "Deaths by age-race-sex" implies complete cross-tabulation, e.g., where it is possible to find deaths of white males of given age. If the table showed whites by age, and males by age, but not the triple grouping described, its title would properly be, "Deaths by age-color, and age-sex." This distinction between partial and complete cross-tabulation may at times be important, since the peculiar usefulness of a given table may hinge solely upon an exceptional degree of cross-tabulation. In indexes to single volumes, confusion upon such points may not give serious inconvenience, but in more comprehensive indexes the distinction becomes more important.

covered that Dr. J. V. DePorte, Chief of the Division of Vital Statistics of the New York State Health Department, had prepared a similar index of the same volumes,* and was preparing a cumulative index of the statistics of his own Division, also. Apparently, therefore, interest in information of this sort is not confined to one person. The writer would appreciate information as to other departments which have made, or are planning to make cumulative indexes of their statistics.

Exhibit III shows a few titles selected to illustrate a form of cumulative index. The meaning and purpose of the symbols in brackets will be discussed below. They are not a necessary part of the title, although useful for certain purposes.

EXHIBIT III

Occupation

Deaths by age-cause-occupation-sex in the Registration Area (28 Causes of death given) 1908 and 1909. Table 11, males; table 12, females. [D:ados;†]

Deaths by age-occupation-sex and by occupation-race-sex in the Registration Area, 1908 and 1909. Table 9, males; table 10, females. [D:aos;ors.]

Parent Nativity

Deaths by age-nativity-parent nativity of foreign born-race-sex, in each state of the Registration Area. (Race includes, White, Negro, Indian, Chinese, Japanese.) Annually, 1900-1910; and 1916-20. [D:anpRS:s.]

Race

Deaths by age-cause-race in each state of the Registration Area. (Race is separated only for states having about 10 per cent, or more colored.) Annually, 1906-1929, except 1921 and 1922. [D:adr's:]

Ibid., for each city of 100,000 population. Annually, 1906-1929. [D:adr'u:]

Deaths by age-cause-race-sex in the Registration Area. Annually, 1923-1929. [D:adrs:]

See also under "parent nativity." [D:anpRS:s.]

* This index has subsequently been published.²

† The symbol *d* (suggesting disease) is used for cause of death, as *c* would, too often, suggest "color."

For convenience, the symbol for "Registration Area" is omitted, that area being understood unless otherwise specified. Separation by states or cities is, however, indicated after the second colon, as shown in the later examples.

It will be found convenient in preparing a cumulative index, to begin by making out an index card for each table in each volume, showing title (verbal or symbolic), year, table number, and page limits. Additional cards are usually necessary for use in cross-referencing.

For some purposes a tabular index, as illustrated in Exhibit IV, is a helpful preliminary to Form III. The parallel column form (IV) has the advantage that omitted years are readily detected, and that long time series can sometimes be built up from shorter series, that are sufficiently similar.

In Exhibits III and IV, table titles are shown in symbolic as well as verbal form. Among the advantages of symbolic titles are the following:

1. As they are much shorter than the equivalent verbal titles, they save much time, effort and space, in writing and re-writing titles on index cards, etc.
2. They permit indexing of even complex titles with the same definiteness, and in much the same manner as words are indexed in a dictionary. Note the alphabetic arrangement of symbolic titles in Exhibit IV.
3. Being very compact, symbolic titles can sometimes be made to convey a quantity of information which would make verbal titles unbearably long.

A brief outline of a code for writing symbolic titles is given in the Appendix.

More comprehensive indexes—It would appear worthwhile to consider whether a consolidated, international index of statistical material for the demographic field as a whole is not practicable. The desirability of such an index need hardly be argued. The field of general literature has its reader's guides; the medical field has its *Quarterly Cumulative Index Medicus* and other indexes,* but there is no single place to which one can go with

* The Statistical Handbook Series of the League of Nations Health Organisation (Geneva) is of interest in this connection; likewise, the practice in such abstract journals as the *Bulletin of Hygiene* (London), of reprinting tables of importance.

a. Abridged list, or less detail than standard (underscored or italics).

b. Greater detail than usual or standard (capital letter).

c. Race shown in areas containing 10 per cent colored, or more.

d. The first figure represents table number; the second and third, initial and final page numbers.

e. Standard summary comprises national aggregates for Registration Area, Registration States, Urban and Rural Parts of Registration States, and Cities in Non-Registration States.

f. 1906 does not have aggregate for Registration Area included in table.

reasonable assurance of finding references to statistical tables of desired content. Is it not possible to develop some form of *Index Statisticus*, which will bring to the field of public health statistics the benefits that have accrued to medicine from comprehensive indexing? The type of index considered would resemble the *Surgeon General's Catalogue* somewhat, in that it would summarize a fairly long time period.

An experimental approach toward an *Index Statisticus* is being made with the aid of the statistical library of the School of Hygiene and Public Health,

where reports are on file from various parts of the world. As assistance is as yet limited and intermittent, the work must progress slowly, and be selective in several respects. It is hoped, however, that this experiment will help to suggest ways of making statistical resources more accessible.

SUMMARY

At present, much valuable statistical material is practically inaccessible for want of proper indexes.

Compiling offices can help to remedy the situation by better indexing of

annual volumes, and through preparation of cumulative indexes of their series.

The question is raised whether it is not possible to provide an international statistical index for public health and related fields. The experimental beginning of such an index on a restricted scale is reported.

A symbolic code for indicating the content of tables is given in the Appendix which aims to give greater compactness, specificity and indexing facility, than is possible with conventional verbal titles.

APPENDIX—PROVISIONAL CODE FOR SYMBOLIC TITLES

As the symbolism here used is still in developmental form, only a few explanatory comments will be offered at this time.

1. *Symbols*—It is obvious that letters are used in place of the significant words of the title, initial letters when possible. Thus the symbolic title, D:ars:s, is derived from the italicized letters of the following verbal title, *Deaths: by age-race-sex: in states*.

Ordinary time or incidence rates take a super bar over the subject symbol; e.g., \overline{D} = death rates; \overline{C} = case rate. Simple ratios may be expressed as such; e.g., the prevalence of illness, or proportion of the population ill at a specific point of time = C/P ; case fatality = D/C .

2. *Sequence*—Colons separate the three parts found in most titles, viz., (a) the subject or thing counted, as births, deaths, etc., (b) the distributions (separations) or specific attributes, as

age and cause of death, but excepting (c) place and time specifications, respectively, which are placed last. The indicated sequence clearly follows the usual order in titles. Subdivision by colons makes it possible, when necessary, to use the same letter in different positions to represent different words. Thus, in D:ads, D in the primary position represents deaths; in the secondary position, disease (or cause of death). Similarly in the example of section 1, s in the secondary position stands for sex, whereas in the place position (tertiary) it can only mean states. In practice, these duplications will be found not to give much difficulty.

To facilitate indexing, symbols between colons are arranged alphabetically, e.g., D:aos rather than D:aoas.

3. *Detail*—Small letters for distribution symbols indicate the standard or usual degree of detail. Capital letters represent greater detail than standard, hence the large letter suggests a large table.* Italics, or underlined letters, represent sub-standard titles.

The standards proposed are less difficult to remember than might be thought at first, since they are the forms most frequently encountered. For age, the standard distribution calls for single years to four, and a total number of classes of at least fifteen; for cause of death the standard is the current *International List*; for race, white and colored; for nativity, native and foreign born; for urbanization, urban and rural.

As example: In Exhibit IV, title

* A relatively simple, but still useful code can be based upon the Appendix text above the asterisk in section 3, plus section 6 and possibly 5. The resulting symbolic titles will usually be at least as specific as conventional verbal titles. The paragraphs relating to sub-standard distributions (italics) and incomplete cross-tabulation (primed letters) cover refinements, which, although important at times, demand added skill and time in their application. It is believed that super-standard detail, symbolized by capitals, should be indicated even in the simplest index. The capital letters will often call attention to rare information, which might otherwise be missed.

(1), *D:adNs*, we find italic *a* and *d*, because age and disease are given in abridged distribution. Capital N is used because the table gives nativity in super-standard detail: viz., by the individual countries of birth.

Single classes are indicated by subscripts; e.g., male sex only = s_m ; colored race only = r_c .

4. Adjacent letters, i.e., those not separated by punctuation marks, (e.g., *adr*), imply cross-tabulation (see first footnote of main text). Incomplete cross-tabulation may be indicated as in the second title of Exhibit III [*D:aos:ors*], or by "priming" the symbols of attributes not crossed with all others; e.g., *D:a'osr'* for the title just cited.

5. *Class interval and range*—When it is necessary to specify class interval

and range, (most often for place or time) parentheses are used in the tertiary position, the first symbol in parenthesis representing class unit, and the second, range. Example: *Deaths: by age-sex, in each state of the United States: yearly, 1925-1930* = *D:as:(s,U.S.)(y,1925-30)*. Ordinarily, the symbol may be omitted for the area accepted as standard in a given index (e.g., a national or state registration area).

6. *List of symbols*—The following list of symbols is incomplete but will suffice for many simple indexes. More specific information, e.g., as to standards and subscript symbols, is available on request to the author.

Note: The author is indebted to Dr. Lowell J. Reed for criticisms and suggestions.

| Primary (subject) symbols | Secondary (distribution) symbols | Tertiary symbols |
|---|-------------------------------------|---|
| B = births | a = age | A. <i>Place distributions</i> |
| B _s = stillbirths | co = climatic factors | n = nations |
| C = cases | d = diseases; cause of death | s = states or provinces |
| D = deaths | d'' = joint causes | u = cities of 100,000 population or over |
| D _i = infant deaths | h = residence allocation (home) | U _{10M} = cities of 10,000 population and over |
| D ^P = standardized death rate† | i = income or wealth indexes | k = counties |
| D ^D = corrected death rate† | k = completeness of reporting | t = permanent census tracts |
| E = life table (expectation) | l = legitimacy | w = wards |
| F = families or households | m = marital state | Z or Σ = sum |
| G = growth data and body measurements | n = nativity | Z _{u,s} = sum of cities and sum of states‡ |
| I = migration (in or out) | o = occupation | |
| M = marriages | p = parent nativity | |
| P = population | q = other hereditary factors | |
| Y = other subjects* | r = race | B. <i>Time distributions</i> |
| | s = sex | h = hours |
| | u = urbanization | d = days |
| | w = seasonal distribution | w = weeks |
| | y = other distributions* | m = months |
| | | y = years |
| | | 5y = quinquennia |

* For use with superscript referring to footnote.

† As defined in Pearl's *Medical Biometry and Statistics*. In these, and other hypothetical rates, a superscript is used to indicate the statistical element of the local community which enters the hypothetical rate. For example, the superscripts P and D, respectively.

‡ Summations lead to rather complex titles: their symbols can often be omitted without serious loss.

"Missed" Epidemics of Septic Sore Throat

PAUL B. BROOKS, M.D., F.A.P.H.A.

*Deputy Commissioner, New York State Department of Health;
Secretary-Treasurer, International Association of Dairy
and Milk Inspectors, Albany, N. Y.*

FROM time to time efforts have been made to compile, from official reports and current literature, lists of milk-borne epidemics recorded as having occurred in the United States. The latest comprehensive report which has come to our attention was that prepared by Armstrong and Parran and published in a *Public Health Report* in 1927. This listed 42 milk-borne outbreaks of septic sore throat as having been recorded in a period of 19 years.

Public Health Reports record 30 milk-borne epidemics of septic sore throat as having occurred in the subsequent period 1927-1932 inclusive. The following list, with the states arranged in order of population, represents the total recorded in the two periods.

| | |
|-------------------------|----|
| 1. New York | 18 |
| 2. Pennsylvania | 2 |
| 3. Illinois | 3 |
| 4. Ohio | 4 |
| 5. Texas | 1 |
| 6. Massachusetts | 27 |
| 7. Indiana | 1 |
| 8. Wisconsin | 3 |
| 9. Minnesota | 1 |
| 10. Iowa | 1 |
| 11. Maryland | 1 |
| 12. Connecticut | 4 |
| 13. Maine | 1 |
| 14. Oregon | 2 |
| 15. New Hampshire | 1 |
| 16. Vermont | 2 |

Total 72

All of the New York state epidemics have occurred outside of New York City and therefore in an area including less than half of the state's population. This tends to equalize the population factor. Sixty-three per cent of the recorded epidemics are "credited" to 2 states, Massachusetts and New York. Eight states have recorded only 1 epidemic and 32 none.

From the record, showing epidemics to have occurred in all sections of the country—North, East, South, and West—it seems evident that there are no climatic conditions anywhere in the United States which insure freedom from this type of infection. Although state lines obviously offer no bar to the spread of infection, there is a marked and as yet unexplained disparity between the numbers of epidemics recorded in certain adjoining states.

There seem to be at least 4 possible factors which might contribute "jointly or severally" to the disparities: (1) Incorrect diagnoses or epidemics erroneously classified as milk-borne, in states recording the larger numbers. (2) Infection more prevalent in some states than in others. (3) Epidemics prevented in some states by effective "milk control." (4) Epidemics overlooked.

For No. 1, we can speak authoritatively only for New York. We have been careful to include in our lists only authentic milk-borne epidemics of septic

sore throat. It seems reasonable to assume that the same care has been used elsewhere. Certainly no state is anxious to be "credited" with epidemics.

It is conceivable that infection might be more prevalent in some sections than in others or that the udders of certain breeds of cattle or of animals under certain conditions of intensive breeding for high milk production might be more susceptible to infection than others. We know of no evidence supporting these possibilities.

Regarding No. 3, we know of no "control" measure practicable for general application, other than pasteurization, which will prevent these outbreaks. In New York, in the aggregate, something less than 20 per cent of milk sold in the cities, exclusive of New York City, is unpasteurized; in the suburban and rural areas it is, roughly, around 50 per cent. If the states with few or no epidemics recorded had a much greater relative proportion of pasteurized milk, this might be significant. If so, it might be expected that Massachusetts, with 9 more epidemics than New York, would show a materially smaller proportion.

About a year ago, addressing an organization of milk control officers in a state which had recorded 2 epidemics to our 18, in the period of approximately 25 years, we expressed the belief that epidemics were being missed. This conclusion was based in part on the fact that 2 of our most serious epidemics had been under way for about 1 and 2 weeks, respectively, before they were "discovered" by the State Department of Health. How many we may have missed entirely in 25 years, we do not know, but it is perhaps a suspicious circumstance that from January 1, 1917, to the end of 1922, none were recorded, whereas in 1929, 1930, and 1931 we recorded 3 in each year. As a result of recent experiences our tentative belief as to epidemics

being overlooked has become almost a settled conviction.

Probably few states are more thoroughly organized for the discovery of outbreaks than New York. All local health officers, approximately 900, are physicians, required to possess certain public health qualifications and removable for cause by the State Commissioner of Health. Fifteen district state health officers, experienced officials, have immediate supervision over their work. Physicians are required by law to make immediate reports to the health officers of cases of communicable disease. The local health officers are in turn required by the state sanitary code to report to the district state health officers cases of certain diseases, including septic sore throat, and also, by telephone or telegraph, outbreaks of any "undiagnosed febrile disease." There are in the state approximately one hundred local laboratories under the general supervision of the State Department of Health; many of them receiving state financial aid on the condition that certain fairly high standards of efficiency have been met. An intensive effort has been made, particularly in the past 4 or 5 years, to bring about the prompt discovery and thorough investigation of all outbreaks of communicable disease, and some of us have been particularly interested in those which might be milk-borne.

On June 13, through a letter from a local resident, the department learned for the first time that there had been an unusual number of cases of sore throat in 2 adjoining rural summer resort villages in northeastern New York. On investigation it developed that between March 13 and June 14 there had been a milk-borne epidemic of approximately 137 cases of septic sore throat, the peak having been on May 20. The health officer's excuse for failing to report cases or any unusual incidence of sore throat was that the

county laboratory had reported negatively on cultures examined for hemolytic streptococci. This laboratory is in charge of an experienced full-time medical bacteriologist and pathologist and has an excellent reputation.

On July 11 the department learned of an outbreak of 17 cases of septic sore throat which had developed a week before in a rural village in the southern part of the state. No report had been received from the health officer. He had recognized and investigated the outbreak, and suspended the sale of milk under suspicion, but the outbreak probably would have gone unrecorded if the department had not heard of it indirectly. It is of interest to note that in 1929 this same village had a milk-borne septic sore throat epidemic of 141 cases.

In July the department learned of an epidemic of at least 200 cases of sore throat, associated with fever and glandular enlargement, which began in May and had nearly subsided when it came to our attention. This was in a

village in western New York. No cases had been reported. Up to the time of writing this outbreak does not appear to have been milk-borne; it is mentioned simply because of its belated discovery.

While we find some consolation in the belief that no milk-borne epidemics of septic sore throat occurring in the state in the past few years have been completely missed, it is evident that when any considerable number can be overlooked even for a matter of weeks the machine is not "hitting on all four." To find and correct the cause of the "skips" is one of our present problems. At the same time, notwithstanding its weak spots, we know that we have a fairly effective organization, relatively speaking, for discovery and control of epidemics. If they can be overlooked here, the same thing can happen—and probably is happening—elsewhere. The record is valuable, so far as it goes, but probably incomplete. The question as to how this condition can be corrected is one in which all of us should be interested.

Memorial Banquet in Honor of Dr. Walter Reed and His Associates on the Yellow Fever Commission at Indianapolis, October 11, 1933

THE SIXTY-SECOND ANNUAL MEETING

AFTER 33 years, our Association has met once more (for the third time) in Indianapolis, and it is not too much to say that it will go down in history as one of the most successful ever held anywhere. The chairman of the local committee, Dr. William F. King, and his aides have made every provision for our comfort and the successful conduct of the meeting. Too much cannot be said in praise of the general arrangements and of the hospitality shown by the people of Indianapolis. An exceptionally good press had been obtained with the result that not only professional people in the city, but the citizenship in general showed great interest in what was going on.

The scientific program was of a high standard of excellence, but the two outstanding features of the meeting were the symposium on epidemic encephalitis given on Tuesday night and the memorial banquet held on Wednesday evening in honor of Dr. Walter Reed and his associates.

The symposium on encephalitis is the first official publication given out on the investigations by the health officials of the City of St. Louis and those of the Public Health Service sent by the government. The hall was packed and the interest shown was intense. We are publishing the papers elsewhere in this issue. We may add that in investigations of this sort, results cannot be obtained for weeks, or perhaps months, but the material given was up-to-date, and constitutes a most valuable contribution to the study of this interesting and more or less mysterious disease.

The Walter Reed Memorial Banquet will go down as a historical event. Its peculiar interest was due to the fact that the first announcement made by Dr. Reed concerning his work was given in 1900 at the meeting of our Association

in Indianapolis. In addition to its significance, the banquet was a brilliant affair. The large dining room was filled to capacity and the close attention shown by everyone, lay and professional, was proof of the interest excited by the event. It was impossible for the older members not to feel some touch of sadness because all members of the Reed Commission are now dead, and of the volunteers who offered themselves for experimental purposes but 4 were present: Dr. Robert P. Cooke, Mr. Levi E. Folk, Mr. John R. Kissenger, whose wife was with him, and Mr. Charles J. Sonntag.

Every attempt was made to obtain the attendance of those who were present at the meeting in 1900, as well as those who were members of the Association at that time. Only 9 were at the meeting. A special table was arranged for them. Mrs. John N. Hurty, the widow of the Health Officer of Indiana, who was our official host in 1900 and who is so well remembered for his excellent work, graced the occasion and was seated with the old members. It may be added that of 19 officers, many of them connected with the Army, serving in Cuba under General Wood in various capacities, mentioned in the report of the Secretary of War, Elihu Root, for 1902, only 3 are known to be living.

The chief address, excellent, and charmingly delivered, was given by Major-General Robert U. Patterson, Surgeon-General of the United States Army. Our knowledge of yellow fever was brought up to date by General F. F. Russell (Retired), whose work on yellow fever under the Rockefeller Foundation is so well known. In connection with the memorial session, the Association is particularly indebted to Brigadier-General Jefferson R. Kean, who was in Cuba while the Reed Commission was working there and who aided it in many ways. His interest in this memorial meeting was as keen as that of anyone and through him we got into touch with practically all army officers of that date who are still living.

Messages of congratulation were received from many parts of the world. Among these we may mention especially those from Major-General Frank McCoy, aide to General Leonard Wood in Cuba, and General M. W. Ireland, formerly Surgeon-General of the Army. From Canada came the warmest greetings from many important organizations and universities. From England, a fine letter was received from Sir George Newman, Medical Officer of the Ministry of Health. Elihu Root, Secretary of War during the time of the Cuban work, sent a most appreciative letter to us through General Kean. For Mexico greeting was brought by Dr. Manuel Madrazo, executive officer of the Federal Department of Health. Another greeting came by letter from Dr. Monjaras who has been a faithful member of our Association for many years and who is remembered with affection by all fortunate enough to know him. Other letters and telegrams too numerous to mention were received and most of them were read to the audience and broadcast.

A storm of applause greeted the following message from President Franklin D. Roosevelt, sent to us directly by the hand of General Patterson and read by Dr. John A. Ferrell, President of our Association:

I have just learned that your association will hold a memorial session to Dr. Walter Reed on Wednesday evening, October 11, 1933, at Indianapolis. This nation today shares with the world untold benefits to public health resulting from the monumental work of Major Walter Reed, United States Army. In definitely establishing the fact that the mosquito is the transmitting agency of yellow fever, he earned the gratitude of humanity. I take great pleasure in joining with you in honoring the memory of this great American.

The roll of honor was read by Dr. William F. King and the survivors were

introduced to the audience. Everyone stood and they were greeted with rounds of applause which lasted many minutes.

Not only were we fortunate in holding our meeting in Indianapolis, where so much connected with the history of yellow fever has been announced, but Indianapolis, itself, was fortunate in again being the scene of such an occasion.

The exhibits in Indianapolis were excellent and were not so badly affected by the depression as we had feared. There was a series of scientific exhibits. These were well arranged and reflect great credit on those who provided them. The commercial exhibits were excellent in character and covered almost every activity in which health officers and health workers, generally, are interested.

The meeting in Indianapolis will be remembered by all who were fortunate enough to attend and will take its place alongside of that of 1900 on account of the special features mentioned.

DEPRESSION AND HEALTH IN ENGLAND

WE have stated in previous articles that the health of our nation has not been affected adversely by the depression, floods, and subsequent droughts as much as health officers expected. We have also given one article showing that in Philadelphia, at least, some malnutrition attributable to the adverse conditions were being noticed. We have been taken to task privately for such statements, though they have been backed by reports which were considered authentic. We now have the statistics on this point from England by the Chief Medical Officer of the Ministry of Health for the year 1932, which are not only surprising but also a matter for congratulation. The Chief Medical Officer states unequivocally "The exceptionally good health of the English people continues to be maintained." He points out that this is a "coldly accurate statement" in spite of the fact that in March, 1933, there was published in a report a statement that "The stark reality is that in 1933, for the mass of the population, Britain is a hungry Britain, badly fed, clothed, and housed."

Giving in detail the facts on which this opinion is based, the Chief Medical Officer quotes reports from 23 districts in England, all made by trained officers of health or by school medical officers. A number of these give comparative observations made by the same man over a period of 9 or 10 years, and the general conclusion is reached that any marked degree of malnutrition among children is not evident. There are cases of decided malnutrition in unemployed men and particularly in women. Some of the symptoms which lead to these conclusions are considered, such as anemia, which is comparatively rarely seen as a result of unemployment. A general incapacity for work is seen mostly in married men, past middle life, who are the heads of large families, and in such cases is contributed to by worry and anxiety. There is noted an increase in the incidence of anxiety neurosis. Among men who show incapacity for work are those who in the past have done very heavy manual labor, such as working on docks and in the mines. They have become physically soft chiefly through idleness. One of the most striking symptoms is the slowness of the recovery-reaction. The observers attribute this not so much to the insufficiency of nourishment as to psychological factors, such as lack of incentive.

The report makes no effort to conceal the untoward social results of unemploy-

ment and industrial depression, though it considers them unassessable. It points out that all observations are based on indisputable statistics collected by competent and skilled observers. The death rates have been steadily declining to the end of 1932, which is as far as this report carries us. It is recognized that there may be much impairment of efficiency and even sickness without the end result of death. Nevertheless, the death rate is one criterion which is absolute, as pointed out by Farr. "There is relation," he said, "betwixt death and sickness; and to every death from every cause there is an average number of attacks of sickness, and a specific number of persons incapacitated for work."

Two features are especially noticeable—the infant mortality has declined to 65 per 1,000 births as compared to 67 for the last 5 years, and secondly, the health of school children is remarkably good. In London children in the 8- and 12-year age groups, male and female taken together, were found to be in better condition than in 1931. There was 1 less per 1,000 found in the subnormal group. These results are attributed to various causes, but chiefly to the fact that the health defenses of the country have been effective and afford a great degree of security in times of special difficulty and danger.

It is especially noticeable also that the English people are learning more of the art of living. Five million children per year have had instruction for something like 25 years through the School Medical Service, and results are now showing. Also there are the Maternity and Child Welfare Services and the School Medical Service which are changing the physical outlook of the people. The nation as a whole has become more health conscious and more humanitarian. For something like 40 years the housing problem has been improving. Approximately one-fourth of the whole population has been rehoused in new or reconditioned dwellings since the World War.

Altogether the report under consideration is distinctly encouraging and England is to be congratulated on the good showing. It is a demonstration of the effectiveness of her method of selecting her health officials, and of the permanence of tenure they enjoy.

TUBERCLE BACILLI FROM THE BLOOD STREAM

A FEW years ago Professor Loewenstein and his coworkers astonished the scientific world by claiming to have cultured the tubercle bacillus from the blood of patients suffering from a number of different affections, many of them not at all connected with tuberculosis. For example, in 82 cases of polyarthritis, tubercle bacilli were cultured from the blood in 56. He claimed also to have demonstrated the organisms in the exudates in the joints. Again in tuberculosis of the skin, tubercle bacilli were cultivated in 62 per cent of 66 cases. In another series of 51 cases, the blood of 38 gave positive cultures and it was concluded from these findings that tuberculosis of the skin is a chronic bacilleamia and the skin lesions were an exanthematic manifestation due to bacillary emboli. Indeed the claims were that tubercle bacilli had been grown from the blood of a number of affections not heretofore believed to have any connection with tuberculosis.

There was naturally some scepticism felt over these results. In 1932 Professor A. Stanley Griffith¹ requested of Professor Loewenstein a number of his cultures for investigation, and in response received 24 strains, 18 of which

were primary and the remainder subcultures from isolations made in 1930 and 1931. Of these, 11 came from cases of skin tuberculosis, 8 from polyarticular rheumatism, 2 from disseminated sclerosis, and 1 each from dementia praecox, renal tuberculosis and phthisis pulmonalis. These were cultured by Dr. Griffith and also inoculated into animals. Seventeen of them proved to be in every respect cultures of the human type of tubercle bacillus, while 7 were avian strains.

This finding opens up a new field. If further observation confirms these findings we may come to believe that a number of diseases, which heretofore have not been considered as having anything to do with tuberculosis, may be due, in part at least, to the tubercle bacillus. As varied as its manifestations are known to be and as difficult as early diagnosis has been and still is, we may be confronted with a problem concerning which much remains to be solved. There can be no doubt, however, that Professor Loewenstein, with his new culture medium and his methods, has succeeded in demonstrating far reaching activities of the tubercle bacillus which were not even suspected up to the time of his work.

LETTER FROM GREAT BRITAIN

THE LONDON SCHOOL

MEDICAL REPORT

During the last few years most medical officers of health and school medical officers, having regard to the economic conditions, have made a particular point of reporting their findings in the matter of nutrition so far as children are concerned. In general they appear to have been impressed by the absence of signs of falling off, and it is practically impossible to find a report in which the note struck is other than optimistic.

Among the latest to make favorable announcement is Sir Frederick Menzies, Medical Officer of Health and School Medical Officer to the London County Council. Both general and special inquiries made during 1932 showed that "no noticeable change has taken place in the condition of the children, and that in London there has certainly not been any perceptible decline in the children's nutrition."

In regard to most other matters investigated in the case of the school children, satisfactory results are reported: the figures, in fact, are claimed

as the best attained since the inauguration of school medical inspection some 25 years ago. Reference is made to a number of special inquiries and activities that have been carried out. The methods adopted in classes for myopic children are described, and general satisfaction with the progress made is expressed.

The scheme for the control of acute rheumatism is shown to be making steady advance, a considerable increase in the number of beds for children suffering from the disease being reported. Increasing attention is being given to immunization against diphtheria, though it is doubtful if this is responsible for the fact that the disease was less prevalent in 1931 and 1932 than in other recent years.

The movement in favor of child guidance clinics is growing, and the few already established are doing most valuable work. Progress in the open-air and special schools continues to be satisfactory and, apropos the retirement of Mr. Macleod Yearsley, the consulting aural surgeon, who urged their

establishment so long ago as 1910, particular reference is made to the great success of the schools and classes conducted for the benefit of the partially deaf.

With the object of "promoting economy in the printing bill," a good deal of material that would undoubtedly have been found both interesting and helpful has been omitted. Space has been used, however, for expressing the hope that it will not be considered necessary to curtail in any essential feature work so fundamental as that of the school medical service "whose aim is to secure such a foundation of health for the industrial population on leaving school as will stand the nation in good stead in the long struggle ahead in the economic sphere."

UNEMPLOYMENT AND THE PUBLIC HEALTH

Sir George Newman in his annual report for 1932 "On the State of the Public Health," devotes a considerable amount of discussion to the relationship between unemployment and national health. His main concern was to discover what was to be learned from vital statistics with regard to the effect of the depression and unemployment. To this end he made an exhaustive examination of all the mortality and morbidity returns that were available and, in addition, of special reports by medical officers of health and under the national health insurance scheme.

The conclusion derived from all his examinations was that the English people, in spite of everything, continued to enjoy strikingly good health; the total death rate for the year (12 per 1,000) was exceptionally low, and the steady decline that has been going on since 1871 has not been interrupted. Of special rates, that of infant mortality is still on the low side and shows no tendency to depart from its downward trend.

Among the individual contributors to mortality in infancy there is no indication of a tendency to prominence in the case of "wasting conditions." In the general list of causes of death, suicide, it is noted, is definitely high; since 1900 the figure has doubled (5,743 in 1932 as against 2,896). That economic conditions may have had something to do with this is recognized, but there is also "the changing psychology toward the act of suicide as a means of release" to be taken into account.

Practically without exception medical officers fail to find noteworthy evidences of privation, and generally Sir George has no difficulty in answering those who are prone to be too pessimistic: the provincial medical practitioner who inclined, like so many physicians, to base conclusions upon inadequate premises, proclaiming that "malnutrition is widespread (in spite of statistics to the contrary) among both children and adults," and those who issued in March, 1933, following a relative study of English public health and housing since 1844, a statement, so very obviously arrestingly phrased, to the effect that "the stark reality is that in 1933, for the mass of the population, Britain is a hungry Britain, badly fed, clothed and housed."

DISEASE INCIDENCE

Perhaps it is because in connection with his unemployment investigation he had to follow such lines, but on this occasion Sir George's report seems to deal more than usual with death and disease, and the provision of hospitals. It is not especially depressing therefore, however, largely because his figures in the main are quite satisfactory.

In the matter of communicable disease, for instance, it is noteworthy that he is in a position to report a reduction in prevalence of nearly all the commoner infections. In the case of those affecting the nervous system the figures

were not too satisfactory, except in regard to encephalitis lethargica which returned the smallest number of cases and of deaths since 1923.

Returns as to tuberculosis afford grounds for satisfaction also, the number of notifications of new cases (69,792) being the lowest on record, and the number of deaths over 2,000 less than in 1931 (33,658 against 35,818). The fact that in the last 10 years the death rate of non-pulmonary tuberculosis has fallen by 37 per cent is again noted.

Of matters other than statistical and epidemiological dealt with, reference may be made to what is said in regard to food and nutrition. In the general press it is this part of the report, indeed, that has attracted most attention, since mention is made at some length of the ill-considered efforts of food producers—bakers, for example—to increase the vitamin D content of various articles by adding ergosterol, and criticisms are levelled against the Englishwoman's capabilities as a cook and a caterer, and English habits in relation to food: meals, says the report, are "monotonous and stale, badly cooked, unappetizing, untidily served," while consumers "bolt their food, or wash it down with tea or beer, forgetting that such a custom is unfair to the food, the tea, the beer, and the body."

THE MISSING SENSE AND THE CLIMATE

To anyone unacquainted with the English it would doubtless create astonishment to learn that these statements, when broadcast in the press, evoked nothing but signs of complete approval. It is notorious, of course, that your Englishman is entirely devoid of all sense of humor. He has earned and perhaps deserves this reputation, I believe, because of the seriousness he displays in the face of comment upon

certain of his characteristics, attributes and such-like products as his climate. Merely he does not react as the commentator from without expects because he agrees. He expects to be told, for example, and believes that the continental housewife and continental cookery are so much better than the home variety. He accepts and does not resent a sneer that his food habits and table manners are so much less refined than those of the Frenchman or the Italian.

To anyone with experience, of course, these statements are the supremest nonsense: of home cookery there is only one better than the English and that is the American, and in regard to food daintiness and fastidiousness the situation is exactly the same. The average Englishman has been brought up to regard himself as inferior in these respects, and there is no room for laughter but only for regret that he has been made that way, and he cannot laugh it off—any more than he can bring himself to regard his climate as a laughing matter, having to live with it and suffer its vagaries with such fortitude and philosophy as he can command.

On the subject of climate, and to permit of comment upon my personal sense of humor, I quote a statement from the annual report of the Ministry of Health in regard to the declining infant mortality rate to the effect that ". . . after the steady process of reduction in the rate during the last few decades, the variations now tend to reflect less the direct influence of maternity and child welfare work than the influence of climatic and related factors. This is shown clearly in the figures for the four quarters of the year, which were 87, 58, 49 and 64, respectively, as compared with 94, 59, 46 and 66 in 1931."

CHARLES PORTER, M.D.

C.-E. A. Winslow, Dr.P.H.

SECOND INSTITUTE ON HEALTH EDUCATION

THE Second Institute on Health Education, held under the auspices of the Public Health Education Section, at the Indianapolis Annual Meeting, was devoted to The Psychology of Health Education. The institute lasted 3 days, commencing on Saturday, October 7, and running through to Monday, October 9. The registration for the institute numbered 56. Five sessions were held. The sessions were devoted to the consideration of:

1. Why the Psychology of Health Education

2. The Psychological Nature of the Recipient of Health Education

3. Fundamental Principles Relative to (a) arresting attention, (b) enlisting sympathy, (c) importing information, (d) leading to action

4. The Meaning and Mechanism of Motivation

One session was devoted to round table consideration and application of

the psychologic principles considered.

The institute which was favorably commented upon by the student body was directed by Dr. Iago Galdston of the New York Academy of Medicine together with Dr. H. E. Kleinschmidt, National Tuberculosis Association, and Mr. Bertrand Brown, Milbank Memorial Fund.

Abstracts on the institute procedure will be made available to the student body within a short period.

IMPORTANT NOTICE FOR MEMBERS WISHING TO APPLY FOR FELLOWSHIP OR LIFE MEMBERSHIP

WITH a view to accommodating eligible members who wish to apply for Fellowship and failed to submit their applications in time to be acted upon at Indianapolis, the Governing Council has given the Committee on Fellowship and Membership permission to accept Fellowship applications after the Annual Meeting, for immediate routing through the various steps incident to Fellowship election. This means that members desirous of applying for Fellowship can do so immediately and have final action taken on their applications within two or three

months, instead of having to wait until the time of the 1934 Annual Meeting.

All eligible members who wish to take advantage of this new arrangement are requested to file their completed and sponsored applications with the Committee on Fellowship and Membership not later than November 30, 1933.

Applicants for Life Membership similarly may have prompt action taken on their applications if they are submitted within the current month and accompanied by an initial payment of at least \$10.00.

NEW LIFE MEMBERS AND HONORARY FELLOW ELECTED AT INDIANAPOLIS

James W. Bass, M.D., Dallas, Tex., Fellow, Health Officers Section

Joseph Blickensderfer, M.D., New Philadelphia, Pa., Fellow, Health Officers' Section

Kendall Emerson, M.D., New York, N. Y., Fellow, Public Health Education Section

Warren E. Forsythe, M.D., Ann Arbor, Mich., Fellow, Public Health Education Section

W. S. Leathers, M.D., Nashville, Tenn., Fellow, Health Officers Section

Arthur T. McCormack, M.D., Louisville, Ky., Fellow, Health Officers Section

Edward L. Miloslavich, M.D., Milwaukee, Wis., Fellow, Industrial Hygiene Section

Harold H. Mitchell, M.D., New York, N. Y., Fellow, Child Hygiene Section

Peel M. Payne, M.D., Napoleonville, La., Fellow, Health Officers Section

Dr. James R. Scott, Albuquerque, N. M., Fellow, Public Health Education Section

William A. Snow, M.D., New York, N. Y., Fellow, Public Health Education Section

L. H. South, M.D., Louisville, Ky., Fellow, Laboratory Section

HONORARY FELLOW

Dr. William Wilson Jameson, Dean and Professor of Public Health, London School of Hygiene and Tropical Medicine (University of London), was elected to Honorary Fellowship in the Association at its meeting in Indianapolis, in October, 1933.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- Walter L. Bierring, M.D., 406-6th Ave., Des Moines, Ia., Commissioner, State Dept. of Health
- Philip E. Blackerby, M.D., 4617 S. 6th St., Louisville, Ky., Assistant State Health Officer
- Henry D. Chadwick, M.D., State House, Boston, Mass., State Commissioner of Public Health
- Walter W. Council, M.D., Juneau, Alaska, Territorial Health Commissioner
- William B. Grayson, M.D., State Capitol, Little Rock, Ark., State Health Officer
- Nicholas A. Kremer, M.D., Corner Walnut and 2nd Sts., Madison, Ind., Jefferson County Health Commissioner
- George W. Larendon, M.D., City Health Dept., Houston, Tex., Director of Public Health
- Manuel F. Madrazo, M.D., Napoles No. 19, Mexico City, Mex., Executive Officer, Federal Department of Health
- J. Edwin Obert, M.D., New Egypt, N. J., Health Officer
- Carl A. Scherer, M.D., 115 Court House, Duluth, Minn., County Health Officer
- Albert W. Sweet, Court House, Freehold, N. J., State District Health Officer
- Frederick J. Swift, M.D., 2414 Kingman Blvd., Des Moines, Ia., Deputy Commissioner, State Department of Health
- George C. Truman, M.D., 103 New State Bldg., Phoenix, Ariz., Supt., State Board of Health
- Frederic W. Wersebe, M.D., Washington, Conn., Health Officer
- Johan C. Wiik, M.D., 408 Bellingham National Bank Bldg., Bellingham, Wash., Whatcom County Health Officer

Laboratory Section

- John H. Bailey, M.D., Municipal Contagious Disease Hospital, Chicago, Ill., Resident Physician
- Olive R. Benham, 208 Farmington Ave., Hartford, Conn., Chief Serologist, State Dept. of Health
- George P. Berry, M.D., School of Medicine, Univ. of Rochester, Rochester, N. Y., Professor of Bacteriology
- Jerome S. Chaffee, M.D., Sharon, Conn., Town Health Officer

David B. Charlton, B.A., Station A., Ames, Ia., Sanitary Bacteriologist, Iowa State College

- Ko Kuei Chen, Ph.D., M.D., Lilly Research Labs., Indianapolis, Ind. (Assoc.)
- Walter S. Davis, B.S., 686 Myrtle Ave., Albany, N. Y., Sanitary Chemist, State Dept. of Health
- Florence C. Drach, B.A., Box 1043, Monroe, La., Bacteriologist, State Branch Laboratory
- E. G. Gerwe, Ph.D., Wm. S. Merrell Co., Cincinnati, O., Director, Biological Laboratories
- Edith Haynes, Ph.D., Indiana Univ. Sch. of Medicine and Hospitals, Indianapolis, Ind., Bacteriologist
- Mary K. Higginbotham, 702 College Ave., Bluefield, W. Va., Laboratory Technician
- Allan C. Hotchkiss, B.S., 745 North Ave., Bridgeport, Conn., Chemist and Bacteriologist, Mitchell Dairy Co.
- Elizabeth McCoy, Ph.D., 412 W. Gilman St., Madison, Wis., Assistant Professor of Agricultural Bacteriology, University of Wisconsin
- Frederick M. Remer, 267 Milbank Ave., Greenwich, Conn., Bacteriologist, and State Chemist
- Thomas M. Rivers, M.D., New York, N. Y., with Rockefeller Institute for Medical Research
- William H. Seemann, M.D., 1577 Henry Clay Ave., New Orleans, La., Bacteriologist, State and City Boards of Health
- Alcor A. Shanks, Nassawadox, Va., Bacteriologist
- Frederick Smith, B.Ch., M.B., Dept. of Bacteriology, McGill Univ., Montreal, P. Que., Canada, Lecturer in Bacteriology
- William L. C. Spaeth, M.D., 5000 Jackson St., Philadelphia, Pa., Director, Clinical Laboratories, Frankford, Northeastern, Kensington and Stetson Hospitals

Vital Statistics Section

- George St. J. Perrott, B.A., U. S. Public Health Service, Washington, D. C., Consultant in Vital Statistics

Public Health Engineering Section

- G. R. Hilliker, City Hall, Fresno, Calif., City Plumbing Inspector

Industrial Hygiene Section

Frederick M. R. Bulmer, M.B., 100 Eastbourne Ave., Toronto, Ont., Canada, Industrial Hygienist, Ontario Dept. of Health
 Karl L. Smith, C.P.H., 290 Congress Ave., New Haven, Conn., Assistant Engineer,
 John B. Pierce Laboratory of Hygiene

Food and Nutrition Section

Glenville Giddings, M.D., Doctors Bldg., Atlanta, Ga. (Assoc.)
 Clarence R. Probst, B.S., Route 1, Torrington, Conn., Charge Milk Department, Torrington Creamery, Inc.
 Oscar S. Tischler, Ph.B., Kirby Health Center, Wilkes-Barre, Pa., Milk Control Officer
 Evan Wheaton, Research Dept., American Can Co., Maywood, Ill., Bacteriologist

Child Hygiene Section

Albert K. Aldinger, M.D., 157 E. 67 St., New York, N. Y., Director of Health Education, Board of Education
 Eleanor Parker, 3319 Dorchester Road, Baltimore, Md., Assistant Supt. of Nurses, Babies' Milk Fund Assn.
 James E. Peabody, A.B., 152 Harvard St., Newtonville, Mass., Author of Text-books in Biology and Hygiene
 Amelia T. Wood, M.D., Ball State Teachers College, Muncie, Ind., Director of Health Service

Public Health Education Section

Lillian W. Burton, Mt. Airy Ave., Paris, Ky., Visiting Nurse, Metropolitan Life Ins. Co.
 Carl F. Deysenroth, 205 W. Wacker Drive, Chicago, Ill., Secretary, Milk Foundation, Inc.
 Olive McCormick, 570 Lexington Ave., New York, N. Y., Director, Health and Safety, Girl Scouts, Inc.
 Willard W. Patty, Ph.D., Indiana University, Bloomington, Ind., Director of Physical Welfare Training

Mary J. Walters, M.D., Vassar College, Poughkeepsie, N. Y., Assistant Physician, and Instructor in Public Health

Public Health Nursing Section

Agnes B. Belser, R.N., 1521 Hanover Ave., Richmond, Va., Assistant Director, Bureau of Nursing, State Dept. of Health
 Eva D. Calhoun, 2803 Gilbert Ave., Cincinnati, O., Local Field Supervisor, Nursing Service, Metropolitan Life Ins. Co.
 Edith S. Countryman, R.N., 612 E. 10 St., Des Moines, Ia., State Director, Public Health Nursing, State Dept. of Health
 Helen S. Harris, R.N., Box 784, Ocala, Fla., County Health Nurse
 Mrs. Charles H. Lyles, R.N., Williamson, W. Va., Mingo County Red Cross Public Health Nurse
 Bessie B. Rappaport, c/o L. Elman, 581 Crown St., Brooklyn, N. Y. (Assoc.)
 Audrey Sanger, R.N., C.P.H.N., 307 Campus Ave., Pullman, Wash., Public School Nurse
 Rosemary Sweinhart, R.N., 326 W. Madison St., Chicago, Ill., Public Health Nurse with Borden Farm Products

Epidemiology Section

Archie L. Gray, M.D., M.P.H., State Board of Health, Jackson, Miss., Director, Epidemiological Unit, State Board of Health
 James W. Jackson, M.D., 463 W. 32 St., Indianapolis, Ind., State Epidemiologist

Unaffiliated

Arthur Eisbein, M.D., 168 Humboldt Parkway, Buffalo, N. Y., Diagnostician, City Health Dept.
 William J. Fordrung, M.D., Hunter College, Park Ave. & 68 St., New York, N. Y., Professor and Head of Dept. of Physiology and Hygiene
 Thomas J. LeBlanc, Sc.D., C.P.H., M.S.P.H., Medical College, Cincinnati, O., Professor of Preventive Medicine

ERRORS AND OMISSIONS

SEVENTH EDITION—STANDARD METHODS FOR THE EXAMINATION OF WATER AND SEWAGE

The following errors and/or omissions have been noted in the first printing of the seventh edition—*Standard Methods for the Examination of Water and Sewage*:

1. Omissions of items in Index.
 - Bile salt agar, 174
 - Boiler water, 157, 172
 - Carbon in sewage, 163
 - Cellobiose test, 171
 - Citrate test, 171
 - Coli-aerogenes English procedure, 172
 - Fecal and non-fecal coli-aerogenes organisms, 170
 - Ferrocyanide citrate agar, 166
 - Lactose broth buffered, 166
 - Media, bile salt agar, 174
 - Media, sulfite glucose agar, 174
 - Sodium citrate test, 171
 - Solids, total, 92, 162
 - Sulfides in sewage, 164
 - Sulfite glucose agar, 174
2. P. 29. Omission. The following sentence should be added to the footnote after the words "distilled water":

"The 'stock' soap solution is approximately 9 to 10 times as strong as the 'dilute standard' soap solution."
3. P. 50. Error in the footnote, the initials of Mr. Mathews should be E. R. not E. A.
4. P. 49. Error. A serious error results from omission of a decimal point. In Section 3 (Preparation of Iron Standards) line 4 should read "about 40 ml., add 0.5 ml. of 3N hydrochloric acid." The text now reads 5.0. The effect of

this is to alter materially the results obtained by the method.

5. P. 158. Omission. During the process of editing the mss. it was agreed that the following footnote should be added to this page:

"Investigations as yet unpublished indicate deficiencies in this method. Persons desiring to determine fluorine are cautioned to familiarize themselves with the literature on the subject after the date of this publication."

It was unintentionally omitted. The following will be substituted in the next printing.

"Persons interested in determination of fluorine should refer to literature on the subject of fluorine determination after 1932 especially to *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 5, 1933, pp. 234 and 236."

6. P. 163. Error in bibliography. "Fairshall" should be Fairhall.
7. P. 166. Error in bibliography. "Dominik" and should be Dominick.

Those possessing copies of the seventh edition are requested to enter the corrections in their copies. Further errors, when and if noted, should be brought to the attention of the undersigned promptly so that corrections can be made before the second printing.

JOHN F. NORTON, PH.D.,
Upjohn Company,
Kalamazoo, Mich.

PUBLIC HEALTH ADMINISTRATION

Extension Course for Health Officers—The New York State Department of Health in coöperation with the Albany Medical College has announced its extension course qualifying physicians for the position of local health officer in communities with less than 50,000 population. The purpose of the instruction is to prepare physicians to assume the office of health officer in such towns, villages and consolidated health districts. The course itself is divided into three parts. Approximately 120 hours of special readings including 20 written tests are first required. This is followed by 8 full days of conference and field work under the leadership of one of the district state health officers. Finally, 1 full week of residence at Albany affords an opportunity to study the clinical aspect of public health work, participate in laboratory work, and observe the administrative phases of the state and local health services.

Tuberculosis Service in Metropolitan New York—The association of tuberculosis clinics in New York City reports that in 1932, 53,509 persons attended the chest clinics of that city. There were included in this group not only diagnosed cases of tuberculosis but also suspicious cases and contacts. These individuals made a total of 134,515 visits. On the first day of the year there were carried forward 9,593 cases and during the year there were 24,991 new admissions and 18,925 readmissions. The number of clinic individuals has increased each year since 1928 when there were 38,852.

Of the 9,593 persons under observation of the district tuberculosis clinics

on January 1, 1932, there were 2,528 who had been diagnosed cases of tuberculosis, the remainder being suspicious and contacts. Among the 24,991 new persons admitted to clinics exactly 4,000 new cases of tuberculosis were found.

Educational and supervisory work has been carried on in homes through the nursing service. In 1932 there were made 41,743 nurses' visits in behalf of clinic cases and 83,727 for non-clinic cases, making a total of 125,470 nurses' visits for the sanitary control and home supervision of tuberculosis cases in New York City.—G. J. Drolet, *Consolidated Statement for New York Tuberculosis and Health Association*, June, 1933.

East Orange, N. J.—The Health Officer of this city has continued to make effective use of the *Appraisal Form* in evaluating his health service and in illustrating his annual report. This city in 1932 scored 912 points in a possible 1,000, and in all services with the exception of cancer control and heart disease control the score exceeded 75 per cent. Perfect scores were recorded for vital statistics, infant hygiene, and sanitation.

With a population of 71,827 the death rate was 9.3. There were reported but 4 cases of diphtheria with no deaths and only 4 cases of typhoid fever with but 1 death. The low diphtheria incidence is ascribed to the fact that 46 per cent of the preschool children are now protected against this disease. In the case of the typhoid fever cases no common source of infection was discovered. Two of the cases had recently traveled extensively and the

other 2 were in the habit of taking many of their meals outside of the city.

Because of the prevalence of rabies there was adopted an ordinance that requires all dogs not confined at home to be either muzzled or kept on leash. The enforcement of this ordinance resulted in a decrease in the number of dog bites toward the latter part of the year. No case of human rabies developed although 18 persons bitten by infected dogs were given antirabic treatment.

East Orange was awarded first prize for 1932 for cities of from 50,000 to 100,000 population in the annual Health Contest of the United States Chamber of Commerce. This city also ranked first in her population group in 1929 and received third and second places, respectively, in 1930 and 1931.

Typhoid Carriers in New York State—The death rate from this disease has decreased from 19.7 in 1908 to 1.0 in 1931. The first typhoid carrier was officially reported in 1911 and since that time 368 chronic carriers have been discovered in upstate New York. Of this number 72 were found through the routine examination of release cultures; 277 were discovered by epidemiological investigation of outbreaks. Only 4 carriers were reported as a result of routine foodhandler examinations. The value of the surgical removal of the gall bladder is discussed with the conclusion that this operation should not be ordinarily advised for the relief of the carrier condition for persons over 50 years of age.—*Health News*, New York State Dept. of Health, 10, 153 (Sept. 25), 1933.

Duties of Health Commissioners—Under the direction of a special committee of the Ohio State University a detailed study has been made of the duties of public health commissioners in Ohio. This work has been undertaken to secure a definite basis for selecting

the content of courses for health commissioners. The duties of the health officers have been analyzed with a view of conducting a short course for commissioners who are already in service. Ohio possesses 180 separate health districts, 92 of which are city units and 88 general county health districts. This district organization was provided for by an act of the legislature passed in 1920 when more than 2,000 independent city, village, and township health units were abolished.

It is recommended that the short course should be 12 weeks in length and divided into two 6-week periods. Based upon a study of the official duties of the administrator the following units of instruction have been chosen: (1) laboratory and engineering technic, (2) vital statistics and records, (3) diagnosis of communicable diseases, (4) public health administration, (5) health education, (6) personal relations.—W. W. Charters and Darwin A. Hindman, *Educational Monographs, Ohio State University Studies*, No. 17, 1933.

Hamilton, Ont.—When Dr. James Roberts was appointed Medical Officer of Health of Hamilton in 1905 the city was spending about \$.30 per capita for public health work, most of which was expended for garbage collection. In 1932 the per capita expenditure of the Health Department had increased to \$.87, and with the addition of the health activities of the Board of Education and the Babies' Dispensary Guild the per capita expenditure was approximately 1.17 exclusive of hospital maintenance.

During this period of time the death rate has decreased so that instead of 2,200 persons dying in 1932 there were but 1,400 deaths, an annual saving of 800 lives. The infant death rate has decreased from 158 to 57.7; the tuberculosis death rate from 121 to 42.3. A most striking example of the control of a preventable disease is the reduction in

the diphtheria and typhoid fever death rates. From a rate of 35 per 100,000 in 1905 diphtheria has been reduced until not a single death has occurred during the past 3 years. The typhoid fever rate has likewise dropped from 35 until the disease is now practically nonexistent.

Cambridge, Mass.—For 1932 Cambridge reports a general death rate of 12.09 per 1,000, slightly higher than the 11.93 rate for 1931. However, the correct Cambridge resident death rate which includes residents of this city

who died outside of Cambridge was 11.3. The infant mortality rate was 56 per 1,000 live babies. Heart disease was the major cause of death followed by cancer. Pneumonia appeared in fourth place and pulmonary tuberculosis in sixth place.

Sixty-nine cases of diphtheria were reported during the year with 4 deaths. One-third of the reported cases and one-half of the deaths occurred in East Cambridge which has only 15 per cent of the population of the entire city. None of the children affected had been immunized.

LABORATORY

PRESERVATION OF MILK SAMPLES WITH BRILLIANT GREEN FOR STREPTOCOCCUS AND ABORTUS EXAMINATION*

C. S. BRYAN

Section of Bacteriology, Agricultural Experiment Station, East Lansing, Mich.

THE ever increasing demand for examination of milk, for the presence of streptococci of mastitis and the abortion organism, presents an important problem to the laboratories concerned. The problem of obtaining suitable milk samples either through the mail or from inspectors is very important. The examination of improperly preserved samples has caused considerable inconvenience and has resulted, in a great many instances, in a reduced quality of market milk.

This reduction in quality is due largely to the subsequent lack of detection of abnormal milk. The milk produced by mastitis infected cows is frequently and intermittently abnormal in flavor and odor to a sufficient degree to impart such abnormality to all milk

with which it later comes in contact. It, therefore, is essential to detect cases of mastitis in the various herds, and thus a cheap and efficient agent for preservation of milk samples for examination becomes essential. Undulant fever infection, in humans, that results from the ingestion of raw abortus infected milk presents another important problem. Such milk that is to be examined must be properly preserved. An agent is herein presented for preservation of milk which is to be examined for either or both streptococci of mastitis and the abortion organisms. This preservative is cheap, efficient, and easily applied.

RESULTS AND DISCUSSION

A number of dyes were compared to determine their preserving action in milk. It was desired not only to have

* Journal article No. 163 (n. s.) from the Michigan Agricultural Experiment Station.

an agent for preservation of streptococcus infected milk and another for abortus infected milk, but to find one that could be used in the same manner for both tests. The length of time during which a preservative is effective is also important; for this reason 20 days was the time covered in this experiment, since it was felt that this would be sufficient time for a sample to be shipped through the mail to a laboratory for examination.

If milk is held at room temperature without a preservative, souring takes place within 48 hours. This is caused by those bacteria that are found in the udder and also those that get into the sample during its collection; the dye inhibits these bacteria from growing. Thus upon cultural examination the infective organisms can readily be isolated and are not hindered by other bacteria that would grow upon culturing an unpreserved sample. The accuracy of the laboratory tests for detection of mastitis depends upon the condition of the sample submitted. The results of such tests are altered upon the growth of some types of bacteria. If curd formation has taken place a uniformly mixed sample cannot be obtained; thus the results would be very inaccurate. Torrey¹ has demonstrated that sour milk will give an unreliable result to the agglutination test for abortus infection of the udder. Thus the need for a preservative agent is readily conceded where refrigeration is inconvenient or impossible.

Of the dyes under study, brilliant green was found to be most suitable as a preservative agent of milk for the problem involved. Brilliant green (1 per cent aqueous solution) was added to the milk at the rate of 0.1 c.c. per 10 c.c. of milk; this made a final dilution of 1:10,000 of the dye in the milk. Gentian-violet in the same proportions can be substituted for the brilliant green. This, however, is not so satis-

factory if the preserved sample is to be titrated for chlorides, due to a masking of the endpoint of titration.

The ability of the dye to preserve the milk is attributed to the bacteriostatic activity which it exhibits. Thus it can readily be seen that care must be exercised at the time of collection of the milk samples, in order that other types of bacteria may not gain entrance. A sterile container is also essential.

The only precautions necessary in the collection of milk samples are: (1) Wipe the udder of the cow, using a cloth moistened with an antiseptic; (2) discard a few streams of milk from each quarter; and (3) milk directly into the container. The preservative may be added prior to collection of the sample, in which case the milk must be added later. In either case a final dilution of 1:10,000 of dye in the milk is essential.

Such preserved milk can be sent through the mail as the samples may be held at room temperature without any changes taking place to alter the results of the usual laboratory tests for detection of mastitis or abortion infection of the udder. The following are the laboratory tests used in mastitis detection: (1) Cultural; (2) leucocytes per c.c.; (3) per cent of chlorides; and (4) catalase. For detection of abortus infection of the udder the agglutination and cultural examination were used. The preservative does not affect any of the above determinations except the titration for the amount of chlorides. Here it causes a change in the color of the endpoint of titration, but does not affect the technic involved. When the preserved milk is diluted with water and potassium dichromate is added the solution is a yellowish green color; the endpoint of titration with silver nitrate is the first shade of a brown color.

Table I presents the results of using brilliant green to preserve naturally streptococcus infected milk. In the

* Catalase tube was used to determine amount of gas.

case of each sample an initial set of determinations was made before preservative was added. Immediately upon the addition of brilliant green another

set of determinations was made. No significant variation was found in the results obtained. A non-infected sample was also included in this study; the results clearly indicate that the preservative did not alter the reactions to the various tests.

The time involved in this study was sufficient for milk samples to reach any laboratory. As the time previous to examination runs over 20 days all the values, in the various tests, begin to drop except in the cultural examination. Here samples have been preserved without change for 3 months.

It is not only desirable to have a specific agent for preservation of milk samples that are to be examined for abortus infection of the udder, but to have an agent that can be used for both or where both examinations can be made on the same sample. Table II presents the data using brilliant green as a preservative for milk samples to be examined for abortus infection of the

udder. As before, an initial run was made without dye, followed immediately and at intervals with determinations on the preserved samples. Again it is noted that the results are constant during storage. The preservative did not alter the reaction of the noninfected sample.

The uniformity of the results obtained, during storage at room temperature, are definite evidence of the value of brilliant-green dye as a preservative for milk samples that are to be examined for streptococci of mastitis or the abortus organisms. The small amount of dye necessary makes it a very economical agent. Its ease of application is ideal; thus the dye may be placed in the container at the laboratory to which a certain volume of milk must be added at the time of collection of milk sample, or milk can be collected into a sterile container and the dye then added in sufficient amounts to make a final dilution of 1:10,000 of dye in the milk. This method of preserving milk samples enroute to the laboratory for examination has been employed for the past few years in our routine work.

CONCLUSIONS

An efficient, convenient, and economical agent is herein suggested for preserving milk samples that are to be examined for either mastitis or abortus infection of the udder. Brilliant green in final dilution of 1:10,000 in the milk is sufficient to preserve milk samples without change, for at least 20 days, in so far as the various tests are concerned. Gentian-violet in the same concentration can be substituted for the brilliant green.

AUTOMATIC PIPETTE WASHER

ELLEN HOWELL AND FANNIE MAE FRANK

Alabama State Board of Health Laboratories, Montgomery, Ala.

ANY laboratory using as many as 100 pipettes a day would find the described washer of great convenience. The jar is filled and emptied every 7 minutes and in an hour over 100 pipettes are washed more thoroughly and more rapidly than if washed by hand or by a suction tube. The jar is of Pyrex glass, $17\frac{1}{2}$ " x $8\frac{3}{8}$ " in diameter, and easily stands drilling without breakage by any glass company cutting automobile glass. The

inlet tube A is 6 mm. inside diameter and the outlet tube B is 14 mm. inside diameter. When the flow of water reaches the hole carrying the outlet tube and bored 2" from the top of the jar, the siphon breaks and the jar automatically empties, and as the level of the water descends in the jar the water in the pipettes drains. After using the washer for a few days the general appearance of the pipettes is greatly improved.

VITAL STATISTICS

Mortality Statistics in the Death Registration Area of Continental United States: 1930, 1931 and 1932 —The Bureau of the Census at Washington, D. C., in a release of September 28, 1933, announced that in 1932 in the death registration area of continental United States (exclusive of the State of Utah) there were 1,304,109 deaths from all causes, representing a mortality rate of 10.9 per 1,000 estimated population. This is the lowest

rate since the annual collection of mortality statistics was begun in 1900. It is estimated that 96.3 per cent of the total population of the United States was included in the registration area for the year 1932. Because of the failure of the State of Utah to furnish the Bureau with death certificates for the year 1932, no data for that state are included in the summary. However, even if the number of deaths which occurred in Utah were included, the

total death rate for each of the 3 years would remain practically unchanged.

It is gratifying to note that of the 18 groups of causes of death into which the summary is divided, 13 showed decreases in the total number of deaths, while only 3 groups had increases, and 2 remained practically the same. The groups which show decreases include infectious and parasitic diseases, chronic poisonings and intoxications, diseases of the nervous system, of the respiratory system, of the digestive system, and of pregnancy, childbirth and the puerperal state. Of particular interest is the decrease in the death rates (per 100,000 population) in certain causes of death such as typhoid fever (which showed rates of 3.6 in 1932, and 4.4 in 1931), measles (1.6 in 1932, 3.0 in 1931), diphtheria (4.5 in 1932, 4.8 in 1931), tuberculosis, all forms (63.0 in 1932, 68.4 in 1931), diarrhea and enteritis under 2 years of age (12.0 in 1932, 15.7 in 1931) and some others. The large decrease of over 9,000 deaths from tuberculosis (all forms), and the drop in the death rate from 71.7 in 1930 to 63.0 in 1932 is most noteworthy. The smaller number of deaths from diseases of the respiratory system (105,555 in 1932 and 110,617 in 1931) may be accounted for largely by the decrease in both bronchopneumonia, including capillary bronchitis (which showed 39,015 deaths in 1932 and 39,977 in 1931) and lobar pneumonia (49,376 in 1932 and 52,950 in 1931). Influenza showed a decided increase (with 36,818 deaths in 1932, and 31,596 in 1931), though the rate of increase for 1932 over 1931 was much less than from 1930 to 1931. The decrease in diseases of pregnancy, childbirth, and the puerperal state (which accounted for 13,241 deaths in 1932 and 14,188 in 1931), was approximately the same from 1931 to 1932, as from 1930 to 1931, and is due in a large measure to the smaller number of deaths from puerperal albu-

minuria and eclampsia and puerperal septicemia.

The smaller number of violent and accidental deaths, (117,370 in 1932 and 124,543 in 1931) is due, principally, to the decreased number of deaths from motor vehicle accidents. The number of suicides increased for the 3-year period, from 18,496 in 1930, to 20,880 in 1932, and the number of homicides was more for 1932 (11,016) than for 1930 (10,590), though less than in the year 1931 (11,134).

The outstanding groups in which large increases were shown were cancer and other malignant tumors and diseases of the circulatory system. The number of deaths due to cancer and other malignant tumors (114,873 in 1930, 117,790 in 1931 and 122,339 in 1932) continues to increase from year to year, and practically every title to which deaths due to this cause are allocated shows an increase in number, if not in actual rates. Of the total number of deaths assigned to this title, 25,802 were of the stomach and duodenum, 14,871 of the uterus, 11,863 of the breast, and 10,420 of the liver and biliary passages.

Deaths due to diseases of the circulatory system increased numerically from 280,403 in 1930 to 294,596 in 1932, equivalent to death rates of 237.5 and 246.2, respectively. This large increase was due, principally, to diseases of the myocardium and of the coronary arteries, angina pectoris; chronic endocarditis, valvular diseases, being the only cause in this group for which there was a considerable decrease in 1932 from 1930.—U. S. Department of Commerce, Bureau of the Census. Sept. 28, 1933.

The Incidence of Endemic Goiter in Northeastern Germany—Analysis of records of physical examination of applicants for immigration visas by residents of the five consular districts

of Berlin, Leipzig, Dresden, Breslau, and East Prussia, brings to light some interesting facts on the incidence of endemic goiter in Northeastern Germany.

The ages of those examined ranged between 3 weeks and 91 years. Thus, 36 males and 53 females were under 5 years, while 83 males and 198 females were over 50 years of age. Larger numbers were included in the intermediate age groups.

The tabulation of results indicates that there were 326 definite thyroid enlargements among the 1,976 males, a percentage incidence of 16.5. Of the thyroid enlargements found, 61.3 per cent, while definite in character, were classified as very slight in size. Only 8 adenomatous goiters were found among the males. Among the 2,320 females there were 727 thyroid enlargements, a percentage of 31.3. Of these, 46.6 per cent were classified as very slight, while 9.4 per cent were definitely adenomatous in character.

In the three lower age groups, namely, from birth to 14 years, approximately the same incidence of thyroid enlargement appeared to prevail in both sexes. However, it is probable that the inclusion of greater numbers of children would have altered the result, making the affection somewhat more frequent among girls. The approximation of the incidence curves of both sexes indicates a considerable amount of endemic goiter in the general population. After 15 the incidence of thyroid enlargement is consistently greater among the females of each age group.

The statistical data show that among boys, the incidence of endemic goiter is greatest between the ages of 10 and 14 years. Among females the incidence of goiter is highest between ages 15 and 24 years. After age 24, the goiter incidence among females is between 10 and 22 per cent higher than among males of corresponding ages.

During the examinations in Berlin, 3 females and 1 male were found to be suffering from Graves' disease. In three additional instances thyroidectomies had been performed at varying periods prior to the examinations without, however, relieving the symptoms of the disease. While the number of persons in the present series who were actually suffering from Graves' disease was relatively small, it is believed that the disease is comparatively frequent in Germany for frank cases are often seen in public.

Additional observations were made for the purpose of determining whether a relationship exists between intelligence and thyroid status. Although many intelligence tests were applied and a number of mentally defective individuals were encountered, there was no evidence that thyroid enlargement or malfunction is commonly associated with mental inferiority.

The results of a survey (similar to that in Northeastern Germany) made of applicants for immigration visas in Northern Ireland revealed a percentage incidence of endemic goiter of 11.8 among males, and 27.4 among females for that territory. Further analysis shows the incidence of endemic goiter in Northern Ireland to be definitely lower in both sexes and for practically every age period than in Northeastern Germany. Just why this should be so is a matter for speculation, as considerable areas of both countries are adjacent to the sea, and it might be expected that goiter would be relatively infrequent in its occurrence.

As shown by the results of the thyroid survey of persons of all ages endemic goiter prevails to a considerable extent in Northeastern Germany, especially among girls and women. Nearly 3 per cent of the females examined had goiters of adenomatous character. Evidences of toxicity were noted in 14.7 per cent of these.

In view of the considerable incidence of endemic goiter and the presence of toxic adenomata, especially among females, prophylactic endeavor appears to be indicated in this section of Germany. Some attention might likewise be directed to the prophylaxis of Graves' disease, which affection is also encountered.—*Pub. Health Rep.* 48:1074-81 (Sept. 1), 1933.

Infant Mortality in Pennsylvania in 1932—There were 10,103 deaths under 1 year of age in Pennsylvania in 1932. This total as well as the rate of 60 per 1,000 live births established a record low mark in infant mortality. A 15.1 per cent decrease from 1931 was recorded in the infant deaths last year, and a 46.5 per cent reduction was registered from 1922. In 1906, the first year of registration in this state, 1 in every 4 deaths was an infant death, while in 1932 the ratio was 1 in approximately every 11 deaths. During the past 3 years the highest infant mortality rate occurred twice in March and once in December, and the lowest in June and July. The excessive rates in the winter months are due to the incidence of respiratory diseases in that season, and the high rates in the late summer and fall are caused by the prevalence then of the gastrointestinal disorders.

Of the 10,103 infant deaths recorded last year, 5,593 or 55.4 per cent were of infants under 1 month, and, of these, over a third were less than 1 day old.

The five leading causes of infant mortality in 1932 were: premature birth with a death rate per 1,000 live births of 16.0, pneumonia 9.9, congenital malformations 6.8, diarrhea and enteritis 6.1, and injury at birth 4.3. Comparison of these rates with those for 1906 shows that the greatest reductions in infant mortality have taken place in the gastroenteric and respiratory diseases. In 1906, diarrhea and enteritis

was the leading one of these five causes of infant mortality, with a death rate of 47.7 per 1,000 live births; pneumonia followed with a rate of 18.6; then came premature birth 16.7, congenital malformations 9.0, and injury at birth 3.4. It may be noted with considerable concern that the death rate from premature birth has shown very little improvement and that the death rate from injury at birth has increased instead of decreased, during this period of 26 years.—*Vital Stat. Bull.*, Pennsylvania State Dept. of Health, Sept., 1933. pp. 5-6.

Marriage and Divorce in Wisconsin in 1932—With the single exception of 1918 there were fewer marriages in Wisconsin during 1932 than for any year since 1887 when the first statistics on marriage were compiled. For 1918 the state recorded only 11,890 marriages and only 14,050 marriages in 1932. Since 1920 when 22,293 marriages were recorded, the marriage rate has steadily declined. The present low rate cannot, then, be attributed wholly to the depression. During the very prosperous years from 1922 to 1929 marriages were declining steadily each year due, in part, it is believed, to marked changes in the economic status of women and the apparent lack of interest in home making on the part of both sexes.

The number of divorces granted and marriages annulled in 1932, as compared with 1931, decreased nearly 300 and is the smallest number reported since 1924. This can probably be charged directly to the depression and the inability to obtain funds to pay for the divorce action. There seems to be no evidence of increased regard for the sanctity of the marriage contract nor any better appreciation of the divorce evil and what it means to civilization. The facts are that many sincere, socially-minded persons, particularly

some prominent sociologists, are now advocating a plan to make marriage more difficult and divorce less difficult. It is granted that the prevention of hasty marriages, if made nation-wide, will reduce the number of divorces even if the divorce laws are not changed. The crying need is for uniformity in both marriage and divorce laws.

Several attempts to liberalize the Wisconsin marriage laws at the 1933 session of the legislature so as to make them conform with the "easy marriage" laws of neighboring states were defeated, making it reasonably certain that there will be no changes in the marriage laws for at least 2 years. If Illinois and Iowa would require a 5-day waiting period after the application for a license is filed, there would be very little demand for amending the Wisconsin laws.

In 1932 with a total of 2,404 divorces and annulments recorded, the husband was the complainant in 452 cases and the wife was the plaintiff in 1,952 cases, while for 1931 the husband was the plaintiff in 553 cases and the wife in 2,149 cases. Over a series of years the wife brings the action and is granted the divorce in about four cases to one for the husband.

The chief causes for divorce as stated in the court action during 1932 were: cruelty in 1,622 cases, desertion in 395 cases, nonsupport in 189, drunkenness in 42, and adultery in 28.

The divorce rate per 10,000 population in 1932 was highest in Lafayette county with a rate of 18. The follow-

ing counties also had comparatively high rates: Dane 13.8, Douglas 13.7, Florence 13.1, Juneau 13, Oneida 15.3, Rock 15.8, Washington 14.9, Waukesha 13.6 and Wood 13. The divorce rate was low in the following counties: Burnett 2.9, Calumet 2.4, Dunn 2.2, Iowa 2.5, Kewaunee 1.9, Marquette 2.2, Oconto 2.7, Pepin 2.7, Taylor 2.8, Trempealeau 2.1, Vernon 2.8, and Washburn 2.7. The divorce rate for the entire state in 1932 was 8 for each 10,000 population or nearly 1 divorce for each 6 marriages solemnized during that year.

Fifty per cent of the divorces in Wisconsin last year were for couples not married in this state. For many of the counties bordering on the states with comparatively lax marriage laws, more than 70 per cent of the divorces were for people married out of the state but having a legal residence in Wisconsin. In some of these counties with a high percentage of out-of-state marriages, investigations show that as many as 85 per cent of the marriages lasting less than 5 years were among persons married in adjoining states. Classifying the 1932 divorces according to the duration of marriage, the report shows that 60 per cent of the divorces were granted before 10 years of married life; of these, the greatest number occurred among persons who had been married for from 5 to 9 years. There is no material change in the duration of marriage now as compared with twenty years ago.—Wisconsin State Board of Health *Bull.* 5:15-17 (July-Sept.), 1933.

INDUSTRIAL HYGIENE

The Pathologic Reactions in Various Pneumoconioses—The present knowledge regarding types of pneumoconiosis is limited by insufficient autopsy material. The diseases caused by pure chemical substances, however, are predominantly either linear (caused by inhalation of inert foreign matter), nodular (apparently confined to silicosis), and diffuse (as in asbestosis cases) in character. Reaction to dusts may be divided into 5 general phases: (1) early diffuse parenchymatous disease due to accumulation of phagocytes and local inflammatory changes in the adjacent connective tissues, (2) linear peri-lymphatic proliferation, (3) beading of the trunk due to chronic proliferative changes in associated lymphoid tissues, (4) enlargement of the mediastinal lymph nodes due to proliferation of the local connective tissues, and (5) late chronic proliferation and nodule formation in the finer connective tissues of pulmonary parenchyma. The different phases are accentuated by the various types of pure dust. Silica produces all the above mentioned reactions.

Animal experimentations indicate that a high atmospheric concentration (200 million particles per cu. ft. of air) of exceedingly fine particles of silica can develop acute silicosis within a period of from 12 to 18 months, with an exposure of 8 hours per day.

Several examples of the pathologic changes due to inhalation of mixed dusts such as coal and silica, and granite dusts are given the characteristic reaction of non-siliceous dusts in a peri-lymphatic cellular connective tissue formation. When tuberculosis infection sets in nodular lesions resembling typi-

cal silicosis were formed without stint throughout all portions of the lung.

Experimental studies with guinea pigs showed that exposures to heavy concentrations of granite dust for a period of 7 months would not produce nodular fibrosis but that exposure to pure quartz dust did develop lesions. In still other experiments it was shown that 74 per cent of the animals inhaling pure silica reactivated their partially healed primary tuberculous infection while with granite dust only 26 per cent developed progressive infection.

These studies, together with the Barre experiences, indicate that only the free silica content of granite dust is of significance in the production of the disease and that the other constituents act as inert diluents. Granite pneumoconiosis, develops much more slowly than that produced by pure silica. It is also possible that the non-siliceous content of the dust may cause a biologic reaction to modify the characteristic effects of pure silica.—Leroy U. Gardner, *J.A.M.A.* 101, 8:594-598 (Aug. 19), 1933. L. G.

Etiology of Silicosis—The primary cause of silicosis is free silica in the form of dust. The dust particles must be less than 10 microns in size to penetrate into the lungs. Silicosis is a disease which develops very slowly (2 to 10 years) and produces a condition of extraordinary susceptibility to tuberculosis. The rate of development of the disease is determined by the dust concentration of the inspired air, silica content of the dust and length of exposure. A few of the contributing causes to silicosis are: (1) preëxisting pulmonary disease other than silicosis,

(2) nasal obstruction or other conditions causing mouth breathing, and (3) conditions of lowered body resistance.

A world-wide distribution of silicosis as an occupational disease has been occasioned by the introduction of pneumatic tools for rock cutting and by sandblasting methods in foundries and potteries. Due to the difficulties encountered in diagnosing silicosis cases the necessity of reviewing the occupational history of the patient for silica exposure is emphasized.—A. J. Lanza, *J.A.M.A.* 101, 8:583-584 (Aug. 19), 1933. L. G.

The Clinical Manifestations of Silicosis—This is a study based upon the examination of 7,722 miners in the Picher District. There was a striking similarity of observations to those noted in the silicosis study in South Africa.

The three stages of silicosis are described and discussed. The cardinal symptom noted was shortness of breath, and the most characteristic sign was decreased chest expansion. In the first stage of silicosis the men usually appeared to be in robust health. No definite physical signs in the chest could be noted in most cases but there were certain constant clinical signs present. There were: (1) lack of elasticity of chest wall during respiration, (2) somewhat reduced vital capacity, and (3) a certain characteristic type of breath sound.

In the second stage of silicosis there is a definite shortness of breath on exertion. Pains in the chest are frequent complaints. An increase in coughing, expectoration, hemoptysis, night sweats, loss of strength and appetite were noted. The men in general, however, appeared to be in good health. The characteristic roentgenographical appearance is a generalized medium sized mottling throughout the lung fields.

In the third stage the shortness of breath is marked and distressing even on slight exertion. The individual's capacity for work becomes impaired. There is a greatly decreased chest expansion, loss of weight, increase in pulse rate, and a dilatation of the heart. Radiographs show a dense fibrosis present in the lungs.

There were only 32 third-stage silicosis cases found. Among the 7,722 men examined 267 cases showed silicosis complicated by clinically active tuberculosis.—R. R. Sayers. *J.A.M.A.* 101, 8:580-583 (Aug. 19), 1933. L. G.

Fundamentals of Asphyxia—The stages of asphyxia are: (1) deficiency of oxygen, (2) deficiency of carbon dioxide, and (3) a series of stages leading to autolysis, fatty degeneration and necrosis. For the second stage in asphyxiation the author suggests a new term, "acardia," defined as the asphyxial diminution in the bicarbonates of the blood.

Chemical changes occur in the blood during asphyxiation, first an alkaline and then an acid shift. Under slight oxygen deficiency in the first state of asphyxiation the increased respiration over-ventilates the blood. The loss of carbonic acid then leaves blood relatively alkaline and a compensatory decrease of bicarbonates or acardia occurs.

The upsetting of the acid-base equilibrium of the blood, as by asphyxiation, has been recognized as a condition known as "acidosis." This condition, however, does not indicate the balance of acid and alkali in the body, as is the popular opinion, but is an index of the state of the respiratory center.

Experimental evidences with dogs have shown that asphyxiation is not a condition of acid intoxication or "acidosis." In a progressively diminishing supply of oxygen a compensatory

acarbica develops with the diminishing carbon dioxide content of the blood (due to over-breathing), and no increase in lactic acid in the blood was noted until the oxygen had fallen to the asphyxial level and the animal was approaching death.

Carbon dioxide in varying concentrations (7 per cent mixture of carbon dioxide with oxygen for resuscitation cases, and a mixture of 20–30 per cent of carbon dioxide in oxygen, or even pure carbon dioxide in cases of deep post-anesthetic depression) has been administered with great success. Carbon dioxide not only stimulates respiration but hastens recovery of normal conditions. It does not "intensify the acidosis" as one might believe in considering the acid-base equilibrium of the blood from the standpoint of physical chemistry.—Yandell Henderson, *J.A.M.A.* 101, 4:261–266 (July 22), 1933. Silicon Dioxide Content of Lungs in Health and Disease—The presence of silicon dioxide was first chemically demonstrated in the lungs of a razor grinder in 1865. Since that time varying concentrations (from 3 to 56 per cent depending upon concentration and length of exposure to silicon dust) of silicon dioxide have been reported in the ashes of normal and diseased lungs. The

analyses of the lungs of six gold mine workers in South Africa showed from 9 to 21.7 gm. of ash per lung of which from 29 to 48 per cent was silica while a normal lung contained 0.73 per cent. Since silica is, next to oxygen, the most common element of the earth's crust it is not very surprising to find silica in the normal lung. Silica is a normal constituent of the connective tissue, skin, blood, bones, nails, urine, feces, and saliva of man.

Analyses were made on 21 lung specimens to determine the average silicon dioxide content of lungs. The normal lung was found to contain about 1.13 mg. of silicon dioxide per gm. of dried tissue. Any lung containing over 2 mg. of silicon dioxide per gm. of dried lung indicates undue exposure to a dusty atmosphere. The silicon content of lungs of 8 persons working in dusty atmospheres varied from 2.4 mg. (machinist) to 26.0 mg. (granite cutter) of silicon dioxide per gm. of dried tissue.

A chemical examination of the lungs for silicon dioxide is suggested in cases coming to autopsy as an aid to a correct diagnosis of silicosis.—William D. McNally, *J.A.M.A.*, 101, 8:584–587 (Aug. 19), 1933. L. G.

Roentgenologic Aspects of Pneumoconiosis and Its Differential Diagnosis—The definition of pneumoconiosis and its most frequent form of silicosis in any simple term is inadequate in the light of recent pathologic and histologic studies and added clinical experience. It is admitted, however, that any comprehensive definition of silicosis or even of pneumoconiosis in general would be too complex for practical use. The proper diagnosis of pneumoconiosis, therefore, becomes a difficult one as well as of extreme importance in a medico-legal problem.

This paper describes and discusses

the differential diagnosis of pneumoconiosis by studying the pathologic phases or stages by means of the roentgenogram. The following conditions simulating pneumoconiosis are described: (1) the perivascular, peribronchial-lymph node phase, (2) passive congestion of the lungs as a result of cardiac decompensation, (3) passive congestion associated with coronary thrombosis, (4) advanced bilateral bronchiectasis, (5) asthma, (6) infiltrating or permeating malignant metastases, (7) polycythemia or erythemia, (8) mycotic infections, (9) nodular metastatic malignant conditions of the lung, (10) actinomycosis, (11) sporotrichosis, and (12) leptothrix infection.

The association of primary bronchogenic carcinoma in connection with pneumoconiosis is discussed with a review of 3 case histories. The predisposition of the Schneeberg and Joachimstal miners to bronchogenic carcinoma is discussed, but the authors

feel that radium emanation and arsenic are the probably etiologic factors instead of pneumoconiosis. Further statistical data are necessary before positive proof of the causative factor can be determined.—Henry K. Pancoast and Eugene P. Pendergrass, *J.A.M.A.* 101, 8:587–591 (Aug. 19), 1933.

L. G.

The Radiologic Recognition of Heart Disease in Pneumoconiosis— This article with 4 case reports and accompanying chest roentgenograms concludes as follows:

1. The roentgenologic sign of hypertrophy of the pulmonary artery and the right ventricle is described, and its importance emphasized.

2. Five cases, with their roentgenograms, are presented to demonstrate how this sign may be utilized to diagnose right ventricular hypertrophy due to pneumoconiosis. Electrocardiograms were made in 4 of these cases, each of which presented right axis deviation.—

John M. Dyson, *Am. J. Med. Sc.* 737: 165–169 (Aug.), 1933. E. R. H.

FOOD AND NUTRITION

Vitamin C Content of Strawberries and Strawberry Ice Cream—Guinea pigs weighing between 280 and 325 gm. were used as experimental animals. Two lots of strawberries were fed—Klondike and Howard Supreme. The fruit was fed as follows: 2 and 4 gm. of fresh Howard Supreme strawberries; 2 and 4 gm. of fresh Klondike strawberries; 3 and 6 gm. of frozen strawberries with sugar; 2 parts berries to 1 of sugar; 10 and 15 gm. of strawberry ice cream, containing 30 per cent frozen-pack berries as above; and 2 and 3 gm. frozen strawberries, no added sugar. The lowest quantity (2 gm.)

fed fully protected from scurvy and produced large weight gains.

Apparently, there was no loss in the freezing and storing processes either with or without sugar. When frozen strawberries were used in strawberry ice cream, they retained their original antiscorbutic potency.

Decreased gains in weight were noted when the fruit was fed in the large doses. This effect has been noted in other vitamin C assays and the authors suggest it may be due to the disturbing effect on the digestive and nervous systems and to the unbalancing of the diet. In spite of poor or negative

weight gains, no scurvy was found on autopsy in any of the animals.—C. R. Fellers and M. J. Mack, *J. Indust. & Eng. Chem.* 25:1051 (Sept.), 1933.

portion and in actual amounts of zinc in the body.—John M. Newell and E. V. McCollum, *J. Nutrition*, 6:289 (May), 1933.

Studies on the Rôle of Zinc in Nutrition—The difficulty of devising diets zinc free or containing only negative amounts of this element has resulted in a lack of conclusive evidence as to the rôle which zinc plays in animal nutrition in spite of its recognized occurrence and biological effect on plants.

Spectrographic examination of the ash of all the foods was employed. A rough approximation as to the content of zinc was undertaken by spectrography, supplemented by the turbidimetric method for quantitative determination. By comparison of both of these tests and painstaking treatment of the rations, the authors were able to secure diets in which the zinc content was less than 1 p.p.m.

Scrupulous care was taken to avoid contamination from the cages and other sources and a list is given of the zinc-free diets. A number of variations in the diets were employed both with zinc-free ration and those to which definite amounts of zinc had been added.

Since growth of the experimental animals took place on diets in which the zinc was present in approximately 1 part in 10 million, it is concluded that zinc is probably not essential as a nutritional factor in the case of the rat. Natural reproduction was more successful in these experimental rats although conception and gestation took place in the case of the parents on a zinc-free diet. Their young had greatly diminished compared to litters from the stock diet.

Analysis of the bodies of the rats showed that the zinc content of the stock rats and others on zinc-containing rations was roughly the same, while rats on the zinc-free diet lost both in pro-

Vitamin Studies VI. Influence of Fertilizers on the Vitamin C Content of Spinach—After extensive investigation of the development of scurvy in guinea pigs, the authors reached certain conclusions regarding the effect of fertilization, as well as lime content of soil, on the vitamin C content of spinach.

When the soil is limed to the neutral point without the addition of fertilizers, spinach has a correspondingly low vitamin content, with balanced fertilization the highest. If any of the ingredients of the fertilizer, potash, phosphoric acid or nitrogen is in excess, in every case the result is a lessening of the vitamin content. Excess of phosphoric acid has the smallest influence, excess nitrogen the greatest.

It will be seen what a significance these findings have on the cultivation of these vegetables for the diet as well as those designed for canning. The cultivation of spinach takes place under world-wide conditions which vary, so that the vitamin C content not alone corresponds to the liming and fertilization of the soil but is affected by secondary influences of the soil which affect the nutritional balance in the plant. Only the cultivation of experimental plants under absolute conditions would guard against deceptive conclusions as to the establishment of the vitamin content.—F. V. Hahn and J. Görbing, *Ztschr. f. Unter. der Lebens.* 6, 65:39 (June), 1933.

Comparative Effect of Tomato and Orange Juices on Urinary Acidity—Previous experiments (*J. Nutrition*, 5:103, 1932, and *J. Nutrition*, 5:519, 1932, -abstract, this *Journal*,

22:1185, 1932) showed that grapes, figs and raisins exerted a marked effect on the urinary acidity. Because of their general use in the diet it was considered desirable to ascertain the effect of daily ingestion of similar amounts of tomato and orange juices.

The present experiments in which 3 normal young men were used, were of 12 days' duration. Each experiment was divided into two consecutive periods. For the first 5 days each person received only the basal ration. During the next 7 days each received, in addition, 1,000 c.c. of either tomato juice or orange juice. The basal diet was the same as that used in the previous experiments and the 1,000 c.c. portions of the juices were used in order that the results might be comparable with the previous studies in which 1,000 c.c. portions of grape juices were used.

With both the tomato and orange juices, there was a generally uniform increase of pH of the urine following their addition to the diet. This increase was such that the pH during the last 3 days of the experiment was from 0.95 to 1.3 pH units higher than that of the 4th or 5th day of the experiment. The tomato juice produced an average change of 1.2 pH units, while the orange juice caused a change of about 1.05 pH units.

Corresponding decreases in both the ammonia excreted and in the total acidity were noted. The average changes produced by the two juices were approximately the same. When either of these juices was added to the basal ration, an increase occurred in the organic acids excreted. The average oxidation of the organic acids of tomato juice was 90.7 per cent while that of orange juice was 93.8 per cent. There appeared to be a correlation between the alkalinity of the ash and the reaction of the urine. A more basic reaction was associated with the higher ratio of soluble alkalinity to insoluble alkalinity

of the ash. The tomato juice exhibited the higher ratio and produced a somewhat greater change in reaction.—L. G. Saywell and E. W. Lane, *J. Nutrition*, 6:263 (May), 1933.

The Calcium Retention on a Diet Containing Leaf Lettuce—Two healthy young women, weighing 52.3 and 50.2 kg., served as the subjects in this experiment. Before participating in the lettuce study they ate a quantity of lettuce which would be necessary to meet the calculated requirement for calcium equilibrium and which would represent a high percentage of the total calcium. During this time the subjects abstained from other vegetables and fruits, but ate similar amounts of food.

During the leaf lettuce experimental period they consumed 54 gm. protein, 83 gm. fat, and 263 gm. carbohydrate which yielded about 2,000 calories. During the pasteurized milk period, subject I consumed 53 gm. of protein, 81 gm. of fat, and 269 gm. of carbohydrate, while subject II consumed 53 gm. of protein, 83 gm. of fat, and 260 gm. of carbohydrate.

The diet for the study of the calcium retention of leaf lettuce consisted of the ordinary strain of Grand Rapids leaf lettuce, lean round beef, soda crackers, butterfat and sucrose. In the milk study the diet was the same except that pasteurized whole milk replaced the lettuce, and apples were added. Distilled water was used *ad lib.* for drinking.

The calcium from the lettuce furnished 93.0 per cent of the total calcium of the diet for one subject and 92.9 per cent of the total calcium for the other, while the calcium from the milk furnished 88.4 per cent for one subject and 88.3 per cent for the other. The calcium of the fresh green leafy lettuce was superior in its utilization to that of pasteurized whole milk. Calcium balances show a daily average as follows:

| | <i>Lettuce Diet</i> | <i>Pasteurized Whole Milk Diet</i> |
|------------|---------------------|------------------------------------|
| Subject I | 0.138 | 0.015 |
| Subject II | 0.173 | 0.032 |

Vitamins C and A in Blueberries

—Two varieties of blueberries were employed—*Vaccinium corymbosum*, the high-bush cultivated type, and the *V. pennsylvanicum*, the low-bush or dwarf type. Scurvy score was determined after the end of each feeding period by chloroforming the animals and examining for lesions. The negative controls died in from 26 to 33 days with an average scurvy score of 16. Two seasons' crops—1931 and 1932—were employed and the berries obtained from Massachusetts, Maine, and Newfoundland.

Preliminary tests on vitamin A on Maine quick-frozen dwarf type blueberries indicated no significant evidence of protection, with the conclusion that these blueberries contained only a trace of vitamin A. In the case of vitamin C, two successive crops of high-bush blueberries indicated a minimum protective dose of 4 to 5 gm. with little or no loss due to quick freezing. Both season's crops of the Massachusetts high-bush type, blanched and canned, with or without vacuum, resulted in a severe scurvy. With Massachusetts high-bush blueberries for two seasons canned without blanching and in

vacuum, there was no scurvy. Low-bush blueberries showed much less vitamin C and variations both seasonal and regional with the best results on the Maine low-bush type. One sample of canned low-bush blueberry showed very little protection from scurvy—C. R. Fellers and P. D. Isham, *J. Agri. Res.* 47:163 (Aug. 1), 1933.

Vitamin A Content of Milk Irradiated by Various Carbon Arcs—

In order to determine the destructive effect on vitamin A of ultra-violet rays, 3 types of carbon arcs were used—the therapeutic "C" carbon, the magnesium impregnated carbon, and the Sunshine carbon. Milk of 1.2 per cent butterfat content was irradiated in thin films and then desiccated and hermetically sealed in jars under inert gas. The exposure varied from 8 to 48 seconds.

After the experimental rats showed vitamin A deficiency, the reconstituted dried milk was fed at levels of 2.5 and 5 c.c. daily. The growth curves on lots of 4 to 15 rats on the experimental feeding period showed practically no variation at either the 2.5 or the 5 c.c. level, as to destruction of vitamin A. The conclusion was drawn that there is no significant destruction of vitamin A in milk containing 1.2 per cent butterfat on direct irradiation under conditions of the test.—R. C. Bender and G. C. Supplee, *Am. J. Dis. Child.* 45:995 (May), 1933.

CHILD HYGIENE

CHILD HEALTH AND CHILD WELFARE IN ENGLAND

RICHARD ARTHUR BOLT, M.D., DR.P.H., F.A.P.H.A.

Director, Cleveland Child Health Association

*At Present on Oberlaender Trust Award to Study Child Health
and Welfare in Germany and Austria*

TWO important conferences on child health and welfare were held in England this summer which the writer had the privilege of attending. The Congress of the Royal Sanitary Institute convened at Blackpool from June 17 to June 24, at which time one of its sections was devoted wholly to problems connected with Maternity, Child Welfare and School Hygiene. The other sections on Preventive Medicine; Architecture, Town Planning and Engineering; Veterinary Hygiene; National Health Insurance; and the Hygiene of Food contributed directly or indirectly to child hygiene. The discussions evoked by the formal papers were right to the point and timely. The entire Congress moved with a precision and orderliness characteristic of British Medical Officers of Health.

The Sixth English-Speaking Conference on Maternity and Child Welfare, organized on behalf of the National Council for Maternity and Child Welfare, under the devoted and able leadership of Miss Jane Halford, took place in London, July 5, 6, and 7. On two days preceding this conference a post-graduate course was conducted for the benefit of those attending so that they might observe first-hand the technics employed at the Royal National Orthopaedic Hospital, Queen Charlotte's Hospital (Maternity) Isolation Block, North Kensington Women's Welfare Center, Mothercraft Training Society

and the Home, and New Princess Elizabeth Hostel. The whole conference brought out clearly the intimate relationship which exists in England between voluntary and official organizations for maternity and child welfare. The fact that advance copies of the conference papers were in the hands of the delegates made possible an intelligent and very lively discussion of each subject.

The address on the Training and Qualifications of Nursery Nurses by Viscountess Erleigh,¹ President of the section on Maternity, Child Welfare and School Hygiene of The Royal Sanitary Institute, so well describes the development of a rapidly growing movement that it may be of interest to quote at considerable length in this place:

The movement for the provision of skilled and trained care of the normal healthy child was commenced in 1892, when Mrs. Walter Ward first conceived and carried through the formation of the Norland Institute for private nurses. . . . Far-seeing women even so long ago realized the demand that was just formulating itself and, as has been amply proved, was bound to increase, for the services of educated women trained to care for the physical and mental needs of the average baby and growing child.

They also appreciated that there were a number of such educated women in the country, who would welcome the opportunity of training, and of the career which has since become known as that of the college-trained, or nursery nurse. . . .

Those who came forward to deal with the

situation, with great wisdom decided to staff the homes that were needed, with young girls of good education, who after such training would be in a position to earn their own living. At just this psychological moment there was simultaneously a great demand, on the part of young women, for independence, and in many homes an economic necessity that the girls should adopt a profession or career. . . .

In 1925 there were 17 colleges and training schools, well known to be efficient and of a high standard of training; but there was no machinery for the interchange of ideas or protection from the numerous little homes that were springing up which, purporting to give a free or nominally free training, took advantage of students coming to them to run their homes cheaply, but gave no real training in return. It was necessary to protect both the established colleges and the prospective students from these conditions.

An Association of Nursery Training Colleges was then formed under the leadership of Hon. Mrs. St. Aubyn who acted as Chairman of the Executive Committee during the first difficult years of its organization.

The Council was constituted so that the representatives of the colleges, the principals themselves, and their matrons or wardens, representatives of the nurses, and representatives of the employers (that is, the mothers) all found a place on it. This body then formulated a standard to which any affiliated college must attain. This was the first attempt to lay down a general standard for the training of nursery nurses—a matter of the highest importance. The fact of affiliation to the Association of Nursing Training Colleges from then on guaranteed that a college was competently run, and the training given sound. . . . As the work of the Association developed it became apparent that in order to sift the numerous applications for affiliation from training schools, and to be certain of maintaining the standard of training among the now numerous colleges affiliated, the Association must appoint its own inspector.

This inspector's chief duty is to report on the training given to students; for while many colleges are under inspection from the Ministry of Health or Local authorities as regards their sanitary arrangements and care of the children under their charge, no inspector existed whose duty it was to inquire into the training of the students received.

The results have shown that the appointment was a wise one.

Last year the Association took a further and most important step—the arrangement in conjunction with the Royal Sanitary Institute of a central examination for nursery nurses. During the course of the year a number of meetings were held at which the matter was fully discussed. Every college, of course, had its own internal examination, both theoretical and practical, and granted certificates to its students who proved successful. A number of the younger colleges, however, had adopted the examination set by the National Society of Day Nurseries as their theoretical examination, and the demand came chiefly from them that the Association should have its own examination. The Association therefore set about discovering ways and means, and finally, after consultation with the Royal Sanitary Institute, decided that they could have no better medium than the Society for conducting their central examination. A syllabus was prepared by a joint committee, and in particular Dr. Fenton gave invaluable help with practical suggestions.

It was agreed that the examination should be optional and not compulsory, and that it should be based on the widest principles of child care and training; in fact that it should embrace all such matters as were considered fundamentally essential in the training of the nursery nurse. . . . Particular care has been taken to keep the syllabus on general lines so as to avoid the possibility of interfering with the special characteristics that particularize many of the colleges. The Association does not want to turn out a regimental true-to-pattern type of nursery nurse. . . .

The examination consists of both written and *viva voce* tests, and the examiners are drawn from members of the Council of the Association of Nursery Training Colleges, and from nominees of the Royal Sanitary Institute. The first examination took place in London last July, and the results were most gratifying. . . .

This year a further advance is being made in the addition of two separate advanced papers, one on child psychology, the other on child nutrition, which are to be open to students who have passed the central examination.

The Association is deeply concerned in the status and welfare of the nurses, and for this reason has opened a club in London to cater to their needs when they are out in posts. It is its object and great desire to raise the status of nursery nurses in every respect, so

that such nurses may become recognized by the public at large for what they are—one of the most valuable and necessary factors in the upbringing of the future generation.

In his presidential address to the Sixth English-Speaking Conference on Maternity and Child Welfare, Sir George Newman, Chief Medical Officer to the Ministry of Health and the Board of Education reviewed the progress made in child hygiene in England and Wales during recent years. He summarized the gains made as follows: ²

1. The burden of infant mortality in England and Wales, though coming to us from the Middle Ages, has been halved in a single generation (*i.e.*, since 1910).

2. This saving of life under 1 year of age has been least in the first month of the first year, and particularly in the first week, and greatest in the subsequent 11 months, a significant characteristic and an indication of the direction of future work.

3. Infant mortality increases with urbanization, from rural to city life, and the urban excess tends to increase throughout the later months of infancy, the months affected by the unfavorable elements of environmental influence.

4. The reduction has been greatest in deaths due to infantile diarrhea and enteritis, to bronchitis and pneumonia, and to whooping-cough, and it has been least in those deaths primarily due to prematurity of birth.

5. Lastly, congenital defects, and principally congenital malformation, have steadily increased in importance among the causes of infant mortality. In 1925 congenital malformation was the certified cause of 3,253 deaths, and in 1931, instead of showing a reduction of, say, 15 per cent (as did the total

infant mortality), it showed an increase to 3,494. In fact, the rate of infant death from this cause rose from 3.98 per 1,000 live births in 1921 to 5.53 per 1,000 in 1931. This variation has occurred particularly in the industrial urban districts of the North, and is in part at least assumed to be due to more accurate diagnosis and certification; but the change and its causes need watching, though we cannot pursue the matter on the present occasion.

He stated further:

We must all, State and voluntary movement, work together for better midwifery and the preparatory stages leading up to it, and for much more thorough nurture of the child under 5 years of age—up to the present regarded, I am afraid, all too commonly as a negligible commodity—by home visitation and domiciliary supervision; by much fuller development of maternity and child welfare centers; by means of day nurseries and nursery schools; and by the use of convalescent homes, hospitals or sanatoria for amelioration, discipline, and direct treatment of the little child before its school days begin. When this movement began, the children coming to school for the first time at 5 years of age were as sorry a bunch of human neglect as could be seen, but today they are much better in every way, and it has been demonstrated at Warrington, Willesden, Darlington, Torquay, in Westmorland and elsewhere, that this hopeful change has been directly due to the influence of the maternity and child welfare centres.

CLASSES FOR EXPECTANT FATHERS

ELDRED V. THIEHOFF, M.D.

Acting Director, Cleveland Child Health Association, Cleveland, Ohio

WHO ever heard of classes for expectant fathers? Due to the efforts of the Cleveland Child Health Association the city of Cleveland lately has heard of such classes for men whose wives are pregnant.

Prenatal classes for mothers have been held in this city since 1922 in connection with prenatal clinics. Here the expectant mothers are instructed not only in matters relating to the prenatal period, including personal hygiene of

pregnancy, but also in mothercraft and child care. The instructor of these classes has been asked so many questions by the mothers as coming from their husbands, that it was realized that the men were not only in need of information but actually were seeking it.

After all, the bringing of a baby into the world is a partnership affair, and simply by the act of his wife delivering a baby, no husband is automatically made an ideal father. The men need to be trained as well as the women. Then, too, many mothers, in properly caring for their baby, meet with the resistance of the uninformed husbands. For example, many mothers state that they cannot keep their babies on a feeding schedule for the fathers insist that babies should be fed when they cry.

In this age of economic depression, many mothers are the bread-earners, leaving the fathers at home to care for the children. In such cases the father surely should know how to care for the child. This is a changing age, and many are entering fields of endeavor formerly thought to be restricted to the opposite sex. We hear of classes in cooking for high school boys, and now classes for expectant fathers.

The first class for fathers was established as an experimental project by the Cleveland Child Health Association at the University Nursing District (a teaching center for public health nurses) with the idea that if it proved to be successful the class later might be established in other parts of the city.

Contacts with fathers were made through the prenatal clinics held at the center, through announcements made in

the prenatal classes for mothers, through nurses making home calls in the district, and through newspaper publicity.

The first class was held on September 6, 1933, one being held each week thereafter for a total of 15 sessions. No charge is made and any man is welcomed.

The first 3 sessions were held by the writer. They covered the prenatal period. Dr. J. J. Thomas, Clinical Professor of Obstetrics at Western Reserve School of Medicine, is now holding the next 6 sessions, which are devoted to a study of the birth of the baby and its care during the first year of life. I shall then hold three classes on the pre-school child, the school child, and common diseases and disorders of childhood. Dr. Oscar Markey, Assistant Professor of Mental Hygiene, Western Reserve University, will conduct the last 3 sessions, covering child behavior problems, discipline, and child guidance.

The class has been very successful, having an enrollment of 35. Each session lasts for 1 hour—from 7:00 to 8:00 p.m. The first half-hour is given over to lecturing and the second half-hour is reserved for individual conferences to discuss privately individual problems. The men are all very interested and have many questions to ask. It is interesting to note that the enrollment includes a graduate of a large state university and a minister. A few of the men come considerable distances from outlying parts of the city to attend the class. It is hoped that this project may be extended in the near future, thus insuring for the community an informed group of fathers.

PUBLIC HEALTH NURSING*

A SCHOOL NURSE WRITES TO THE STATE
BUREAU OF PUBLIC HEALTH NURSING

Her Letter—"We have a problem on which we need advice. The Community Chest is going to feed the poor children in our schools. The children are to be chosen by the teachers who make home calls on all their families. The food is served at noon in an empty room. It is prepared, taken to the schools and served by women who are in need of employment and are being helped by the community chest.

"These are the usual menus with some variations:

Monday—Bean soup and crackers, fresh apple, milk.

Tuesday—Jelly and peanut butter sandwiches, apple, milk.

Wednesday—Vegetable soup (ground meat included), apple, crackers, milk.

Thursday—Hot dog sandwiches, stewed fruit, milk.

Friday—Chili and crackers, apples, milk.

"The teachers prefer the milk lunches twice a day for it is not so messy. However, they will do whatever is best for the children. What is best?

"The expense was about \$100 per month last year. It will be more this year for the food is higher and there are more children to be fed."

Our Reply—"It is hard to say what, in general, should be done about feeding children at school for each community situation is different. The latest and most authoritative advice we have about supplementary feeding is that in the White House Conference Publications, *Growth and Development of the Child*, and *The School Health Program*.

"This report says, 'The school should feel obligated to provide a lunch at school whenever the distance is too great for the children to go home at noon or when they would not receive a suitable lunch if they went home.' This leaves no question about the school's responsibility to furnish a noon lunch for the children who have too little to eat at home.

"There is, however, a question about the value of the mid-morning and afternoon milk lunches. This same publication makes these recommendations:

"'Because it stays so long in the stomach, milk is of questionable value when fed in the middle of the morning at school to children who have poor appetites.

"'Even if breakfasts are inadequate, children should be taught to eat them at home; milk and fruit should be increased in the home diets rather than introducing an extra meal at school.

"'Milk may not be the food needed. The type of food that will best supplement the home diet should be chosen.

"'The wisdom of feeding all children or merely the malnourished should be carefully considered.'

"Have you thought about the most important step in planning—a strong central committee? On this committee should be a representative from the Community Fund to care for financial matters, a representative from the Medical Society, yourself (the school nurse), and the home economics teacher to supervise selection and service of food, someone to represent the school to arrange for selecting and transporting the children and some reliable women of the community to supervise buying and preparation. Such a project as this needs careful planning and organization.

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

"You as school nurse can help so much by suggesting time of serving, methods for handwashing, helps for maintaining the right mental attitude of children, parents, and workers toward the project, and by helping to make it an educational affair. You can also help the teachers in their investigating and selection of children by checking with physicians, relief organizations, Red Cross, trustee, attendance officer, etc., and by adding to theirs your knowledge of the home conditions of the children. The selection should be based not on underweight or present signs of undernourishment but on the basis of feeding those children who are not having and cannot have adequate food at home, with the idea of preventing a condition of malnourishment."

V. A. J.

PUBLIC HEALTH NURSES AS HOME HYGIENE TEACHERS

A short time ago we had the chance to attend a Home Hygiene Instructors' Conference given by an American Red Cross Nursing Field representative, and it was very inspiring to see how interested some 30 public health nurses were in the instructions, and how eagerly they took part in discussions.

The majority of the nurses present who were teaching home hygiene classes had never had any training in the principles of teaching, and this institute opened up a new world to them. They were especially enthusiastic about the morning program in which the following "Criteria for Teacher Evaluation" upon which each nurse was asked to grade herself, were discussed:

- A. The function of the teacher in the educative process is to guide and direct the activity or experience presented by the teacher with the approval of the pupil or set up, through pupil initiative, so that the best possible results, compatible with the educational objectives, may be attained.
- B. In order that the teacher may function

with maximum efficiency the following facts must be considered:

1. Strong physique and good health are essential to continuous success in teaching.
2. A pleasing, well-modulated voice and clear enunciation are important qualifications for teaching.
3. The teacher should be well groomed and appropriately dressed.
4. The teacher should use clear and correct English.
5. The teacher should know the subject he is teaching.
6. The teacher should understand and use the principles of good teaching.
7. Among the qualities desirable in teachers, the following are important:
 - (a) *Self-control*, the ability to maintain a well balanced poise at all times.
 - (b) *Tact*, the ability to handle all sorts and conditions of people with skill and discernment.
 - (c) *Decisiveness*, the ability to make a decision promptly and stick to it.
 - (d) *Enthusiasm*, an invaluable tonic for both teacher and pupils.
 - (e) *Resourcefulness*, the ability to turn an unexpected situation to good use.
 - (f) *Sympathy*, the ability to understand and appreciate the point of view of another person.
 - (g) *Fairmindedness*, the ability to think impersonally and to act justly.
 - (h) *Open-mindedness*, the ability to see all sides of a question.
 - (i) *Sense of humor*, skill in handling the humorous situation cleverly.
 - (j) *Fairness*, ability to mete justice, sincerity, frankness.
 - (k) *Diligence*, adequate preparation to handle the work efficiently.
 - (l) *Originality*, ability to enrich the experience with novel variety, interesting materials and activities.
 - (m) *Initiative*, ability to put a program across.
8. Teachers should not talk too much. Pupil activity is more important than teacher activity.
9. Teaching is a *cooperative project*. The problem is the acquisition of the desired knowledge, habits, attitudes, and ideals by the pupil through the skillful guidance of the teacher.
10. Skillful guidance is at all times conditioned by the professional habit of the teacher-pupil.

E. F. M.

FEDERAL FUNDS FOR VISITING NURSING

One of the most important milestones in the history of public health nursing has been reached with the announcement that federal funds will be made available to provide bedside nursing care in the homes of "recipients of unemployment relief."

The announcement affects to some degree most agencies giving bedside care on a visit basis. This care will be paid for from the funds of the Federal Emergency Relief Administration at a flat rate per visit "not to exceed the certified cost per visit established for accredited visiting nurse associations in the state or local district."

The full plan is published by the F.E.R.A. in a bulletin called "Rules and Regulations No. 7" and may be secured from state or local relief administrators. Presidents of state or local professional organizations will be called upon, under the plan, to designate com-

mittees to consult with relief administrators on the formation and "adoption of adequate programs for medical, dental, and nursing care in the homes of indigent persons."

Immediately on receipt of the news, the N.O.P.H.N. sent out a memorandum to State Health Departments; Presidents of State Organizations for Public Health Nursing; Presidents of State Nurses' Associations; and to its own corporate agency members.

Long before this plan was made public, representatives of the National Organization for Public Health Nursing were called into consultation with Harry L. Hopkins, F.E.R.A. administrator, in relation to the establishment of the principle that bedside nursing care should be provided from public funds for those in families of the unemployed on relief funds who are sick at home.—News Release—National Organization for Public Health Nursing, Oct., 1933.

EDUCATION AND PUBLICITY*

HEALTH DEPARTMENT LEADERSHIP THIS FALL

THE local Health Department has a fresh opportunity this fall for expressing leadership in the field of public health education.

The calling of a conference or a group of conferences of local health agencies and cooperating groups could be one useful form of leadership.

United We Stand—And Go Forward—Get and give a perspective of the winter's activities in health education by calling a conference, or several conferences in larger cities. Invite all health agencies, all social agencies concerned with any aspect of health, and

the varied organizations of adults and young people which have health as an accepted feature of their program.

The representatives might be cautioned to restrict their statements to purely health education activities. Each might be asked to answer as concisely as possible such questions as these:

What subjects will you emphasize?

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

What audiences or groups do you expect to reach?

What will you do in the way of talks, printed matter, bulletin boards, articles in bulletins or house organs, motion pictures, etc.?

Where will you get your materials?

What information do you need?

What special events do you plan?

What coöperation would you like to receive?

What materials would you like others to use for you?

Following each report a few minutes might be given for questions from those present.

In some cities mimeographed summaries of the answers might be desirable and practicable.

Where the health department does not feel free to take the initiative may it not be done by the health council, the council of social agencies, the social work publicity council, or by an individual agency?

Letters to Editors Will Help—

Please write letters to newspaper and magazine editors when you like their articles on health and other welfare subjects.

Sincere letters of appreciation from people who have read an article are always welcome to the editor.

Articles in local newspapers have one kind of value to health work. Articles in other types of periodicals, whether they are local or general in their circulation have another kind of value. The two supplement each other in their help to health work.

Nationally circulated periodicals are particularly useful in reaching leaders in the groups touched by their circulations.

Please write to the editors.

How It Looks to Them—The September bulletin of the Social Work Publicity Council contains examples of the effective interpretation through experience stories. A letter to the editor

in *New York World-Telegram*, August 22, is quoted with this comment:

The skill in the letter lies in his picking out one point which epitomizes his feeling of helplessness as month after month spent in bed goes by. "When we are well we take pants as a matter of course. They are just the things that we wear in order to keep up with the Joneses. But maybe we never have realized that it is possible to develop a real affection for pants. You get so you lie awake at night in a hospital and keep saying to yourself: 'Oh, if I only could have a pair of pants!' When the nurse comes in you say as nonchalantly as though you were reaching for a Murad: 'Good morning, Miss Brown. Will you kindly bring me my pants?' Certainly she won't. Your clothes have gone into hiding, feeling naked and ashamed, no doubt, because there's nobody inside of them. Well, one morning the nurse came into my room at Grasslands and said: 'We are going to let you get up and dress today.' Just think of that! After 13 months I was to be permitted to wear pants. Not only pants, but a shirt, a coat and a vest—a tie, even."

Radio Coöperation—D. Oberteuffer, professor of physical education, Ohio State University, Columbus, writes about a project in

Radio broadcasting over our University station, during which periods we will give current events and topics of public interest relating to personal and public health. I am interested, of course, in making these broadcasts scientifically accurate first of all, and interesting to the laymen at the same time. If, from time to time, your association distributed literature of one kind or another which might be suggestive of some material for these broadcasts, I would be happy to receive such and to use it with proper care and due credit to your organization.

Please address Professor Oberteuffer as noted above.

Local Motion Picture Clinics—

The amateur movie offers a practically new medium for reaching many audiences with practical health teaching or the presentation of the activities of health departments and other health agencies.

Showings of pictures produced in other cities offer the simplest and best

material for studying amateur picture technic.

The health officer could take the initiative, or the health council, the health division of the council of social agencies, or an individual health worker. Gather a group of health workers (others interested in amateur pictures would be helpful), and arrange for screening pictures which may be available. Discuss each picture, searching for lessons in picture technic, and their application to the problems of those present. Make notes which might interest the producer of the picture discussed.

The editor of this department will give information about pictures from other cities.

Planned Objectives for Literature Distribution—The 1929-1933 report of American Society for the Control of Cancer states that—

Before 1929 the Society was broadcasting great quantities of its literature to those who, for one reason or another, requested it. On paper this produced a somewhat impressive showing. With the appointment of additional field representatives, however, it soon became evident that such a procedure measured the gross rather than the net educational value of our work.

There has, therefore, been developed a policy by which the distribution of literature to specific groups for a definite objective has gradually replaced the former method. Since education may be fairly measured by the number of minds affected, just as marksmanship may be evaluated by the number of hits on the target, the change is a wise one. It has further led to a more carefully prepared type of literature. Each new pamphlet is published to fill a definite educational need.

At the present time, more and more of our distribution is being made at the specific request of our state chairmen and field representatives and is an integral and important part of planned and organized local educational programs. The indiscriminate and extensive broadcasting of printed material is folly, both from an educational and a business point of view. While the total amount of general distribution has normally declined, the cost of the literature to

be distributed has not declined in like proportion. This is due to the fact that our booklets have been materially improved both in make-up and in size.

The report also tells of a series of 13 brief news releases available for local use. Also—

A series of 16 radio broadcasts of varying lengths, with instruction sheet, has been prepared and is being widely used, particularly in the southern states where active educational campaigns are now in progress. Radio broadcasts from other sources are being mimeographed for distribution, with the objective of eventually building up an extensive library of such material.

Motion pictures are supplied for medical audiences, as well as exhibits, chiefly for medical groups. Address the Society at 1250 6th Ave., New York, N. Y.

Reporting via Mimeograph—Accompanying the 1932 Annual Report of the Knoxville, Tenn., Bureau of Health is a slip reading as follows:

This publication was compiled and mimeographed entirely by regular employees of the Bureau of Health who will welcome the receipt of any comments, suggestions, or criticisms.

It is a beautifully done piece of work, quite ambitious in some details—56 pages, 8½ by 10¾ inches, green paper, plus 8 black pages, 4 of which carry quotations, a table of contents, and an index. Partly in two colors, with numerous statistical tables and diagrams, all done with neatness and accuracy, and evenness of touch on the whole job.

Another very attractive mimeographed report is called *Common Cents* issued by the New York Tuberculosis and Health Association with the same note that—

This report has been prepared at our own office to save the expense of printing.

In fact the office cost of 5,000 copies is \$175 against the printing cost of \$350. 27 pages, 5½ by 8¾ inches; on both

sides of the sheet, which added to the production difficulties.

Miss Maier describes the very careful preparation that a mimeographed report comparable to printing must go through:

In setting up a book of this type it is necessary that before the final copy goes to the mimeographer all re-editing, spacing, etc. be absolutely completed, and a perfect example of what the final mimeographed book will be like. I believe it was necessary to type and draw our book over six or seven times before the final version was ready—these various re-typings corresponding to the re-setting of lines, re-dummyings, etc., that would take place on printers' proofs. In this particular instance the situation was greatly complicated by the fact that the text had to run around the drawings so that in correcting "widows" and other bad makeup it was necessary to reset the whole page in order to see how far down the text then came with the drawings on the page, instead of being able merely to shift lines around as one could do when there are no drawings interfering. Then, too, such a change—say on page 5—would automatically affect pages six and seven, and since the typing had to be done on folded pages on which five would be on one side and twenty-four the opposite page, both of these leaves would also be affected by the changes.

In short, as you may guess from the above, it was a very, very wearying and tedious job, and while I think the drawings greatly liven up the text, a book without them could be done in about one-fourth the time.

Hygeia for October, 1933—"Waiting for the Doctor and Making the Doctor Wait" (a cartoon); "Heart Disease—Then and Now"; "A Housewife Looks at the Committee on Foods" (of the A.M.A.); "Worm Powders" (ignorance is not always bliss); "The Curse of the Fire Spirit" (fire dangers); "The 'Demon' Housekeeper" (a symptom, not a vice); "Salvage" (reclaiming the "Polio" victim); "Should Your Child Wear Glasses?" "At a Century of Progress" (illustrations of scientific exhibits); "Wings of Death" (what quarantine does); "Safeguarding the Athlete's

Health"; "Progress in Preventive Medicine" (part 8); "Training for Athletics and Health" (part 10); "The Old-Time Doctor"; "Craftsmanship in Canning"; "Sex Education" (part 4—The Teaching of Sex to the Young Child); "I Want to Know" (part 2 of "A First Physiology"); "New Books on Health"; "School and Health," including "The Passing of Half Truths in Health Education," several examples of teaching methods and materials and "New Health Books and Teachers' Materials." — *Hygeia*, 535 North Dearborn St., Chicago. Oct., 1933. 25 cents.

A Health Education Exhibit—
An exhibit which enlivened an annual meeting is described in *Public Health Nursing* for October, 1933.

The Cleveland Health and Parent Education Association made its customary methods of teaching health and care of the sick demonstration at the annual meeting to which 1,000 invitations were issued.

We felt that our aims had been realized: we had been able, first, to interest an infinitely larger number of people than we could have done with the usual annual meeting and, second, our visitors will henceforth know what is taught in health classes and how it is taught. Furthermore, many are interested enough now to pursue health education for themselves and to interest others in doing so.—

ETHEL M. HANSON, R.N.

To Editors of Health Bulletins and Magazines—An editorial writer on a metropolitan daily was persuaded by William McAndrew to read the editorial pages of over 200 educational magazines. Mr. McAndrew in a talk to the Educational Press Association of America in February, 1933, reported the conversation following his reading.

Perhaps some of us who write editorial pages need to take the conversation to heart.

"This is the worst afternoon," my victim said, "that I have had in many moons."

"What's the matter with them?" I said.

"Nothing," he replied. "That's the trouble with them. They don't matter. These claps don't write their editorials until the last minute. Nothing worth while can come to a man the last minute. An editorial writer must be composing editorials all the time. When he hears a speech or reads one, when he glances through a magazine or, as he must to keep alive, when he reads the books of a master, he must out with pocket notebook and jot down the by-products that snap into his mind. Just as a reporter gets so that everything he sees and hears is analyzed by him for its news value, so the editor is perpetually looking for editorial ideas. He runs over the large events and finds an idea that his paper should push with vigor and punch. He digs into his memory and into his books for illustrations or arguments to enliven his theme, but his ideas flash on him everywhere. The pocket notebook, small size, with detachable leaves, is an indispensable tool of the journalist. Your editors show no sign of having any."

That's a little thick, but it seems to contain a usable idea.

For Camp, Club or Institution—
You may have a group of children or adults for whom you wish ideas or inexpensive materials to provide simple entertainment or occupation, or incidental education.

An aid in that direction is "Illustrative Materials and Publications," a 5-page memorandum which explains and gives information for securing the source publications whereby you may locate a vast array of pictures, slides, motion pictures, posters, exhibits, plays, story-telling helps, etc., etc. References to specific health material are limited, but there seem to be important uses for other subjects in hospitals, sanatoria, summer camps, and elsewhere.

Reception rooms of clinics, for example, might be more attractive and restful for the occasional use of non-health material on the walls or in the slide or motion picture projector.

"Illustrative Materials and Publica-

tions" is supplied by Social Work Publicity Council, 130 East 22d St., New York, N. Y. 6 cents; 2 or more copies, 5 cents each. ☉

Professionals as Volunteers—It started in this idea penned by Alma C. Haupt in *Public Health Nursing* (Aug., 1933—"Informing the Public and Money Raising"):

Even though agencies cannot employ full- or even part-time special publicity workers, they may carry the work through a publicity committee of the board, with the help of the nurse director and the staff. Every large community has writers, artists, and advertising experts who make helpful members of this committee.

To answer a query as to what local nursing agencies were making use of writers, artists, and advertising specialists, Miss Haupt wrote to 10 of the locals. Here are extracts from their replies.

"During one year we were able to have a professional person give us about one-half day a week in which she wrote letters to the newspapers, articles, etc., that would give us publicity for our service. As you know, we did not attempt through this publicity to get funds but simply to tell the community about our service."

"We have had some help from a newspaper writer on rewriting some of our newspaper stories. We have also had posters made by the students of the art department of the local high school. We have never asked aid of an advertising expert, but that might be an advisable thing to do."

"We have not had the value of writers, artists or advertising experts on our Publicity Committee since I have been in — but I believe that it would be desirable, provided the professional writers, artists, etc., and the remainder of the committee would work together on their projects. I recall two instances where the professional newspaper person on a V.N.A. job found it difficult to put his emphasis in the places thought important by the V.N.A. I think some V.N.A.'s labor under certain publicity inhibitions which may or may not be good for their organization, and which are quite often difficult for a professional newspaper person to understand."

"We have at present on our Publicity Com-

mittee Mr. ——— who is secretary of the ——— newspaper and a newspaper man of considerable standing, obviously. We also have Mrs. ——— who was publicity and finance secretary of a national organization before her marriage. We do not have other members who are specialists. I think the idea sounds excellent where they are available and where the board considers members outside of its own board of directors for members of the committee."

"Our publicity we believe should be headed up by some member of the Board who would draw on members of the association and community for assistance. This delegation of responsibility has not yet been done. The chairman of our Nursing Committee has been of great assistance in securing publicity for the organization, however."

"I enclose our annual report which has original illustrations to show how we used the artistic ability of one of our Association members, who is the wife of a local physician. Mrs. ——— is now making a series of five posters using stick drawings to decorate our booth at the local Exhibition, which is to be held in September. She is illustrating our Nutrition Service in a way that we think will attract attention for its humor and originality. Our exhibit is entirely on the subject of nutrition this year. We have no writers of note in ———. I wish that we did. I realize how valuable assistance from one would be. Your letter convinces me that we should reach out even farther in the coming year to find aid in publicity and attach such persons to us through membership in our association where their abilities might be drawn upon in the interest of public health nursing."

"To date we have not used professional people in these groups on our Publicity Committee. We have, however, always had board members who showed what might be called a flair for publicity on the Publicity Committee, and our Annual Report Committee has been made up of people who were particularly interested in that type of publicity. We have used professional people indirectly, as for instance securing assistance from an advertisement writer who is the husband of a Branch Committee member, and the preparation of the graphic part of the Annual Report by an artist interested in the V.N.S."

This department would be glad to report any public health agency making use of outside specialists as volunteers in health education or presentation of the work of the organization.

One way to get new people interested in what you are doing is to get them to do something for you. It does not seem necessary to get them to join or otherwise formally to align themselves with your agency before asking them to help.

On the other hand it is better, usually, not to ask any untried persons to become committee members. As a rule it is safer to get their aid on particular jobs, try them out, awaken their interest, and inform them as to what you are doing and why. An invitation to committee membership may follow.

How and where to use the outside specialist will be discussed next month.

IT MAY BE HERE

Two men meet outside the office of "Dr. Jones." One man: "Hello Jim! How are you this morning?" Other man: "I'm fine! And I *know*: I've just had my annual physical examination." This is the story told by an illustration in *Health Bulletin*, Board of Health, Brookline, Mass. Sept., 1933.

"We Got Those Kiddies in the Nick of Time" is a 4-page illustrated folder explaining the Health Restoration Camps financed by the Community Chest, Cincinnati, Ohio. Enclose 3 cents for a sample. (But *why* did it not say "Kids"?)

"Statistics for All: The Fact Picture from Vienna is Significant Visual Aid," in *Educational Screen*, 64 E. Lake St., Chicago. Sept. 1933. 25 cents. With 3 examples of work by Dr. Neurath. (Those who wish to work with visual education departments of schools cannot well do without this magazine.)

"A Health Education and Publicity Program" is a reprint of articles from *American Journal of Public Health*, May and June, 1929. These articles were part of the two half-day sessions in which were discussed why plan, objectives, audiences, the facts, and the approach, are almost indispensable to those doing or supervising popular

health education. Copies of the reprint free from Russell Sage Foundation, 130 East 22d St., New York, N. Y.

Mouth Health Quarterly, 84 S. 10th St., Minneapolis, Minn., July, 1933, contains interesting reproductions of paintings on dental subjects, and of exhibits at Century of Progress; reproductions of well done mouth hygiene posters from Great Falls, Mont., school children; "Your Child's Teeth" (radio talk); "Jack and the Chew-Chew Fairy" (mouth health story); several pages of comment on publications such as public health workers wish to know about. Special contributions have enabled the American Mouth Health Association to reduce the *Quarterly* subscription to \$1.50 a year.

Another car card from the New York Tuberculosis and Health Association:

CLEANLINESS — GOOD FOOD
ADEQUATE REST — FRESH AIR
SUNSHINE — MEDICAL CARE

These help to prevent and to cure tuberculosis

The last sentence is run in red in one line across the card. Below it is As-

sociation name and address in white letters on a broad black band.

MAGAZINE ARTICLES

"The Depression and Our Health," by C. H. Gellenthien, M.D. *Kiwanis Magazine*, 520 N. Michigan Ave., Chicago, Ill. May, 1933. Interprets some mortality statistics; emphasizes possible future losses. 15 cents.

"I Bluffed My Way to Health," by W. C. O'Connell. *Saturday Evening Post*. Oct. 7, 1933. But exercise turned the trick.

"Making the Most of Sun Rays," by W. R. Ramsey, M.D. *Farmer's Wife*, St. Paul, Minn. May, 1933.

"Stroke Your Broom," by R. C. Moore and Janet Lane. *Collier's*. Sept. 23, 1933. How to change hard work into desirable exercise.

"Traffic Crimes and Criminals," by C. Billings. *Atlantic*. Oct., 1933. Unique police prevention of automobile deaths.

"Water Cure," by M. B. Ray. *Collier's*. Sept. 2, 1933. The varied values of the bath.

BOOKS AND REPORTS

Health and Environment—By Edgar Sydenstricker. New York: McGraw-Hill, 1933. Published under the direction of the President's Research Committee on Social Trends. 210 pp. Price, \$2.50.

Mr. Sydenstricker defines environment as all those circumstances and conditions which affect man's health and well-being, excepting inheritance, and his book is a discussion of as many of these as there seems to be any chance of evaluating by the methods of statistical analysis.

The book is far more than a statistical treatise. It is an epidemiological monograph in which unusual trouble has been taken by a capable and experienced worker to find explanations for statistically expressed facts and to discover whether statistics can be adduced to demonstrate certain assumed truths.

Tables of data and diagrams made from tables abound, but they seem not to have been inserted so much to prove the coördination of health with environment as to show trends which call for explanation.

A subject candidly treated, and in need of general acknowledgment, is the fact that so many social and economic factors enter into the problem of lengthening life that it is impossible to ascribe all the improvement in the conquest of disease to the efforts which have been made directly against it. Tuberculosis, for example, is helped by whatever improves the social and economic status of the individual.

Some diseases, as smallpox, diphtheria and typhoid, against which specific and effective means of preventive or curative treatments exist, have,

of course, been reduced to an extent which statistical records well show. Certain industrial hazards have been eliminated or reduced, and tables are available to indicate these results.

It is interesting to see that the author declares that the span of life has not increased in recent years, although the average age today is greater than formerly. This, he explains, is due to the saving of life during infancy and adolescence.

The book is valuable for the frank and fearless way in which it deals with its subject. It deserves to be carefully studied by every health officer and epidemiologist, and should be in the library of all who wish to be well informed on public health values.

GEORGE A. SOPER

Social Planning and Adult Education—By John W. Herring. New York: Macmillan, 1933. 138 pp. Price, \$1.25.

In a period when social planning is a pressing need, this story of group thinking and planning in Chester County, Pennsylvania, is especially welcome. The author, who was director of the county health and welfare council, describes frankly the county's effort to study itself, to evaluate its problems, and to develop constructive programs.

A social planning program was begun before the war, having been locally conceived and initiated. Later, plans were devised in conjunction with the American Association for Adult Education, to use the county for adult education. These two undertakings were merged in 1929, the resulting project having three chief characteristics: (1)

county social planning, (2) the use of the county unit in adult education, and (3) the conscious use of adult education in making and carrying out a social plan. The movement "conceives, in a nutshell, that planning, the most comprehensive of social tasks, should be undertaken with education, the most effective of tools."

Consideration is given to both the successes and failures of the projects undertaken. There is much philosophy written around certain of the projects. Those engaged in county health and welfare work will find suggestions worthy of study. IRA V. HISCOCK

Water Pageants, Games and Stunts

—By Olive McCormick. Philadelphia: Barnes, 1933. 138 pp. Price, \$2.00.

This new and very interesting book with a foreword by Commodore Longfellow presents, not only to the beginner in pageant work but to the expert, a number of new and novel suggestions on water pageants.

Chapters are also found on costuming, make-up, music, scenery and lighting, how to write a water pageant, swimming formations, stunts, games and canoe regattas and a complete write-up of seven other pageants.

The organization of the material is to be commended. It logically presents the "how" of preparing such exhibitions and demonstrations and would be very helpful to those in camps and to people who are doing indoor swimming pool work where demonstrations are used for propaganda purposes.

HELEN COX

The Control of Football Injuries—

By Marvin A. Stevins, M.D., and Winthrop M. Phelps, M.D. New York: Barnes, 1933. Price, \$3.00.

This very interesting and instructive work which grew out of the criticism of the game of football and its associated

injuries is well worth careful study by anyone having any connection with an athletic organization. While it is primarily a detailed consideration of football injuries, their prevention and treatment, a great deal of the material can be applied to all other branches of sports and even to ordinary civilian practices and injuries.

The reviewer found a great deal of interest in the first chapter, which is concerned with training and physical equipment. Apparently Yale University has an adequate financial rating to carry out an almost ideal training system, which smaller colleges may find difficult; but in general, the principles laid down can be followed in any institution devoting a fair amount of attention and energy to sports.

Many of the chapters are devoted to a detailed consideration of all injuries possible, the greater majority of which never occur, and when they do, are usually competently handled.

Many doctors, who have been interested in sports, either as spectators or as medical advisors, have been distressed by the large number of preventable injuries and needless recurrences of those at certain typical points—knees, ankles, and shoulders. The time lost both from the standpoint of the team and the individual player reaches an enormous figure during a season. Everyone who reads this book will be impressed with the clear, concise exposition of the production of an injury, its prevention, and its treatment, and thus gain a more adequate conception of the control of football injuries.

The last portion of the book is devoted to the tabulation of the individual fatalities of the year 1931. The collegiate and high school fatalities indicate the advantage of competent medical supervision of the players, for in the sand-lot and unclassified group there are noted several instances where

delayed hospitalization and medical treatment might be considered as contributory to the fatal outcome.

The book is profusely illustrated with photographs showing certain definite mechanisms for producing typical injuries which should be instructive to any coach or trainer. The keynote of prevention of injuries is felt throughout the work and is in harmony with every phase of modern medicine and public health. WILLIAM J. STEWART

Procedures in Tuberculosis Control for the Dispensary, Home and Sanatorium—*By Benjamin Goldberg with a chapter on Sanatorium Planning by Thomas B. Kidner, and an Introduction by David J. Davis. Philadelphia: Davis, 1933. 373 pp.*

The author, as Dr. Davis says, has seen fit to analyze and criticise various methods, procedures, and institutions evaluating them chiefly in terms of control. The book is divided into three sections. The first deals with the general problem, legislation, and the dispensary, to which most space is devoted. Here are to be found many suggestions concerning records, charts, dental clinics, valuable for those engaged in such endeavors. The second section discusses home treatment and the third the sanatorium.

Individual plans must be fitted to the needs of the individual city. The importance of the negro and Mexican problem in relation to tuberculosis is discussed. From figures given, the author estimates that there are 10 times as many patients with tuberculosis as there are beds available, which emphasizes the present importance of home treatment. The danger of the open case for the children in the household is stressed and attention called to the fact that in Chicago the number of these cases has been reduced to a minimum. Legislation is divided into enabling and coercive.

Throughout the book the need of coöperation with and protection of medical men is urged. Plans, personnel, and routine of the dispensary, education and publicity are freely discussed. Recognizing that the majority of patients sooner or later must be submitted to home treatment, details as to how this can be managed through the clinic are given. Following a detailed description of how a sanatorium should be conducted in the interest of public health, a helpful bibliography for those interested in the control of tuberculosis, as well as an index is given.

The book will prove to be a valuable help to all workers in tuberculosis for it covers many subjects that ordinarily are to be found only after much search scattered in many journals. It should be at hand for reference for all workers in tuberculosis. LAWRASON BROWN

Proceedings of Southern Branch of the American Public Health Association, Held at Birmingham, Alabama, November 14, 15, 16, 1932. New York: American Public Health Association, 1933. 100 pp. Price, \$.50.

The Southern Branch of the American Public Health Association was founded November 14, 1932. It has published here the proceedings containing its minutes, Constitution and By-Laws, and the papers read. The Western Branch submits its papers to the *American Journal of Public Health*, and then sends those which cannot be published in that *Journal* to other magazines which wish them.

The papers read were of excellent quality, and almost all of them had special reference to problems found in the southern section of our country, though some of them are of general application. We note particularly the paper by Dr. Leon C. Havens on the detection of typhoid carriers, which is characteristically accurate and shows

the quality of mind for which he was noted. His death since the meeting is a cause of regret to every member of the Association.

This volume possesses a value on its own account in addition to being the first publication by the Southern Branch. We have no doubt that the high standard set will be continued at future meetings.

MAZÛCK P. RAVENEL

What Shall I Eat?—By Edith M. Barber. New York: Macmillan, 1933. 106 pp. Price, \$1.75.

The author, lecturer on history of cookery, Household Arts Department, Teachers College, Columbia University, has written here a clear and comprehensive explanation of the uses of food to man. The facts are stated simply enough to be understood by persons not versed in the fields of science.

If every one could read the chapters on "Those Diet Fads" and "Those Food Prejudices," general conversation regarding these everyday topics would be materially changed.

Common sense menus are given for the ordinary daily diet, reducing diet, business man's or woman's diet, and weekly menus for a family of 5 at different cost levels. Changes which can be made and still meet the requirements of an adequate diet are noted.

This book is written in a humorous vein and should meet the needs of home folks, women's clubs, etc., as well as students and teachers of cookery.

BESS EXTON

Dictionary for Nurses—2d ed. Compiled by Lois Oakes. Philadelphia: Reilly, 1933. 351 pp. Price, \$1.00.

While Miss Oakes has supplemented the dictionary of medical terms in this small book with several tables meant to increase its usefulness, it still does not seem to be comprehensive enough to be adequate for general use.

A table of calorific values of foods lists only 9 articles of diet: three tables for infant feeding are given without any qualifying statement such as is found in our government bulletins, that all artificial feeding should be under the direction of a doctor.

The 4-page list of abbreviations of British degrees and diplomas would be of only occasional interest.

ALVA ANSTEAD

Nutrition—By Graham Lusk. New York: Hoeber, 1933. 142 pp. Price, \$1.50.

In the pages of history the aspirant to knowledge finds revelation and learns wisdom. In this, the tenth in the interesting series of primers on the history of medicine, he will find the narrative of the development of nutritional chemistry. He will not find the story of modern dietetics, but he will learn its important background.

Graham Lusk, eminent authority on physiology and biochemistry, completed the manuscript of this little book a few weeks before his recent death. In it he has presented in chronological order the events which led to the establishment of the newer knowledge of nutrition, and he has described with skill and perception, and often from personal experience, the men who have contributed most to the chemistry of foods.

The book is well printed, has 13 illustrations, and a good index, and it will prove of interest to all who seek to delve into the historical background of such a significant topic as human nutrition.

JAMES A. TOBEY

Milk, the Indispensable Food—By James A. Tobey. Milwaukee: Olsen Publishing Co., 1933. 200 pp. Price, \$2.25.

This book presents a number of essays which describe in a popular manner the many good qualities of milk and dairy products. The book is in-

terestingly written and conforms to Dr. Tobey's best style.

Essentially, the details are correct and the views maintained are modern and backed by ample authority. Use is made of the unusual and the out-of-the-way to stress certain points and to keep up interest. The popular presentation of the results of many nutrition experiments is particularly well done and brings constantly before the reader the indispensability of milk to the welfare of man. Some repetitions occur; and a very few errors.

The book can be heartily recommended to anyone who is desirous of learning something of the most interesting story of milk. Like milk, this book is easily digested and should be fully prescribed by all whose interests are in better health. C. R. FELLERS

Children's Sleep—By Samuel Renshaw, Vernon L. Miller, and Dorothy P. Marquis. New York: Macmillan, 1933. 242 pp. Price, \$2.00.

This is an interesting report of a series of studies on the influence of motion pictures and coffee on children's sleep, on the effects of loss of sleep, and on the critical frequency limen for visual flicker in children.

In making the study, the sleep movements of 170 children of both sexes, ages 6 to 18 years, were recorded during 347 nights. These children, in groups of 20, slept in single beds, each fitted with an electrical device which recorded the changes in posture made by the sleeper, minute by minute, throughout each night. The records of the study include a total of 3,591,000 minutes of sleep. Children of the Ohio State Bureau of Juvenile Research at Columbus were used as subjects. It was felt that these children represented a fair sampling of an average child population and that the regularity of living conditions at the bureau favored the general applicability of conclusions

based upon the experimental results.

To study the influence of motion pictures upon the sleep of children, successive groups of children were shown 58 different motion picture programs in the evenings before retiring. Increases in motility ranged from 0 to over 90 per cent. On the average, boys showed about 26 per cent and girls about 14 per cent greater hourly motility after movies than in normal sleep. The changes in motility were greatest in the fore-part of the night, when sleep normally is at its maximum. Children below 10 years of age were less influenced than the older children, the maximum effect occurring at about the age of puberty.

In studying the effect of coffee on children's sleep, it was found that coffee, in so far as motility is taken as an index, does not have the consistent detrimental effect on sleep that it is generally assumed to have. For some children coffee affected the sleep motility during the first 1 to 3 hours of sleep, for others during the middle of the night, and for a few it seems to raise or lower the general level of the motility curve throughout the night. Individual differences were so great that it was impossible to make general statements regarding its effect on children of the same sex or age.

An interesting section of the book is devoted to a study of the effects of loss of sleep on children. It was found that the effects of loss of sleep in children, where the deprivation has amounted to one-third of the normal ration, extended into several nights and that a single night is not sufficient for complete recovery.

The final chapter considers the problem of whether the intermittent illumination of the screen gives a flicker which induces eye-strain and nervousness in children attending a motion picture. Some interesting conclusions are herewith drawn.

Although this is a report of a series of experiments, it is given in a very interesting manner and will prove well worth the reading. It leads the reader to look forward to the final report of the larger and related group of investigations of the influence on children of motion pictures and their social potentialities, sponsored by the Payne Fund of New York.

ELDRED V. THIEHOFF

The Common Cold—By David Thomson and Robert Thomson. London: Baillière, Tindall and Cox, 1932. 738 pp. Price, \$15.00.

This consists of a monumental compilation of the world literature dealing with various aspects of inflammatory disease of the upper respiratory tract. The volume is a large one containing 738 pages and many excellent plates. Workers in the field find it the best reference book extant on the subject of colds. Its size will naturally limit its employment by the casual reader.

It is unavoidable that a work of this kind should suffer from a lack of continuity and consistency, in spite of the efforts of the authors to arbitrate conflicting points of view and to inject into the subject a critique based on personal bacteriological investigations.

It seems unfortunate that so much space should be devoted to a laborious description of the bacteria encountered in the upper respiratory tract at a time when the cultural and morphological changes encountered in bacterial dissociation are common knowledge. The authors seem rather reluctant to abandon their preconceived ideas as to the primary importance of these bacteria as the inciting agent of colds. Evidence is rapidly accumulating to support the hypothesis that filtrable agents are usually the factors of primary importance, and the rôle of bacteria is that of secondary invader of tissue previously damaged. The recent cultiva-

tion of such filtrable agents by Dochez and his coworkers demonstrates beyond question their existence, while the marked variation of bacteriological findings in the nasal secretions during a single outbreak of coryza points strongly against the etiological significance of ordinary microorganisms.

It is of little importance if the personal views of the authors do not meet universal acceptance. The style, the care and accuracy, and the thoroughness with which such a mass of knowledge has been organized and abstracted excites the reader to unbounded admiration.

FRANKLIN M. HANGER

Selected Recreational Sports (for Girls and Women)—By Julia H. Post and Mabel J. Shirley. New York: Barnes, 1933. 127 pp. Price, \$2.00.

The New Deal offers more leisure time. The machine age brings in its wake shorter working hours and the problem—what are we going to do with this time? Our educational program has neglected to prepare us to meet the situation adequately and this book offers some helpful suggestions.

The activities presented in the volume require little equipment at a minimum cost for small groups. Although the volume was prepared for girls and women the material presented is also adapted to boys and men or mixed groups.

The following sports are presented: deck tennis, horse shoe pitching, badminton, table tennis, shuffleboard, clock golf, paddle tennis, and tetherball. Suggestions for the organization of a sports program, the care and sources of equipment, and diagrams for setting up play areas for these sports are given.

The book is well worth while and should find a useful place in the home, at the club, in the school, at the playground or wherever sports of this type have a place.

HUBERT E. BROWN

Abderhalden's Handbuch der Biologischen Arbeitsmethoden — Vol. XIII, Book 2, No. 8. Berlin & Vienna: Urban & Schwarzenberg, 1933. Article 1—*Auswertungsmethoden für Pockenlymph und Pockenserum*, by Stravros Zurukzoglu, pp. 1141–1190, 12 figs. Article 2—*Das Anaphylatoxin*, by E. Friedberger and J. Weissfeiler, pp. 1191–1242, 3 figs. Price, M. 5.80.

The first article in this instalment of Abderhalden's handbook of biological technic is a comprehensive survey of the evaluation of smallpox vaccine and vaccinia antisera.

After a short discussion of the fundamental principles, the author describes the various methods of testing the potency of smallpox vaccine on human subjects, calves and rabbits. Complete details are given of the methods approved by the smallpox commission of the League of Nations. These comprise the technics of Gins, Groth, Sobernheim and Calmette-Guerin, under the latter method being considered its modifications including that of Force and Leake.

A section follows on the testing of dry lymph and a suggestion is made that governmental agencies concerned with the supervision of biologic products should maintain a standard dry lymph with which could be compared samples from producing establishments. The next section lists the countries officially testing their vaccines and the methods used.

The testing of vaccinia antisera is discussed in a similar manner. In view of the fact that vaccinia immune serum has been used in the treatment of the encephalitis following vaccination, the author amplifies a suggestion made by Groth in 1930 to the effect that such sera should be prepared, standardized in terms of neutralizing units, and made available for emergency use.

In an appendix are assembled certain

Prussian orders and circulars dealing with the testing of smallpox vaccine and the treatment of encephalitis following vaccination. There is a rather complete bibliography. JOHN N. FORCE

In the second article the authors review only the more fundamental papers in this field, which still awaits satisfactory clarification. They define anaphylatoxin, using this name in lieu of serotoxin of Doerr, Jobling and Petersen, and Wells, or proteotoxin of Zinsser and Dwyer. The technics of Novy and Kruif and of Friedberger are described, and the antigen-antibody-complement reaction *in vitro* is described. The methods of demonstrating anaphylatoxins without specific antibodies and by Abderhalden's reaction, with bacteria and with trypanosomes, with animal bacteria with plasma instead of serum, *in vivo*, from toxins, and from peptone, are described. The physico-chemical and the biological characteristics of anaphylatoxin are reviewed and their action on isolated organs of sensitized animals is described. Toxicity is acquired by serum after centrifuging out an admixture with kaolin, after exposure to minimal amounts of agar, after mixing with starch paste which leaves in suspension in the serum colloidal starch particles, after shaking with chloroform or ether, and after dilution with distilled water. Various theories of the source and method of origin and the chemical nature of anaphylatoxin are enumerated but none are free from difficulties. The authors express the hope that this review of the problems, largely still unsolved, of anaphylatoxins will stimulate efforts to solve them.

C. A. KOFORD

The First Two Years: A Study of Twenty-Five Babies. Volume II—Intellectual Development — By Mary M. Shirley. Minneapolis:

University of Minnesota Press, 1933.

513 pp. Price, \$3.00.

A study of the development of 25 babies during the first 2 years of life has been made. Volume II gives a detailed account of the intellectual development. Volume I, published in 1931, considered the postural and locomotor development. Volume III, to be published in 1933, will take up manifestations of the development of personality. This study is interesting in that it consists of weekly observations or tests made in the homes instead of in a laboratory.

This volume is divided into 3 parts:

Part I reports on the sequence of development in:

(1) Eye coördination; (2) Fine motor skills; (3) Speech; (4) Social habits; (5) Comprehension.

Part II gives detailed descriptions of the methods of examining or testing the babies.

Part III attempts to summarize all of the bits of behavior developed into a meaningful whole. Here the author concludes that behavior development follows a consistent sequence in all babies and that this development proceeds in harmony with biological laws.

The book is well written, and the material is presented in an interesting manner.

ELDRED V. THIEHOFF

The Tides of Life: The Endocrine Glands in Bodily Adjustment—
By R. S. Hoskins. New York:
Norton, 1933. 352 pp. Price, \$3.50.

In view of the marked interest of the public in the progress in endocrinology and because of the many spurious claims made by those who are seeking to use this interest as a means of personal gain, this volume is a most valuable addition to the library of the intelligent layman. The book is doubly valuable because of the author's investigation in this field of physiology. He does not try to discuss the technical details of the subject which in a volume written essentially for lay consumption would be out of place. The facts are given in non-technical language and where technical terms are used, full explanation is given.

The subject matter is discussed first from the standpoint of the hormones in general as the chemical regulators of the body, with a brief history of the growth of the subject. Following this the author takes up the various glands in order with their function and their relationship to each other as far as is known at the present time.

Besides devoting considerable space to some of the more recent developments in our knowledge of the sexual functions, the author also discusses endocrine dysfunctions such as diabetes, and the motor and secretory functions of the digestive tract which are not generally treated of in textbooks on endocrinology.

The book is well written and should appeal to a large group of the intelligent population.

MAZÏCK P. RAVENEL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

The Ups and Downs of Rheumatic Fever—The declines in incidence of rheumatic fever seen in certain New York hospitals from 1897 to 1919 and its increase since then is discussed from the angles of foci of infection, cycles of virulence, rainfall and economic conditions.

DAVIS, J. S. Incidence of Rheumatic Fever in New York City Hospitals. *Am. J. M. Sc.* 186, 2:180 (Aug.), 1933.

More About Dental Caries—Is tooth enamel a vital substance? It appears to increase in hardness, it is stainable, calcium seems to be extracted in pregnancy, but the author presents evidence which suggests that enamel is an inert substance. The corollary offered is that we must combat caries by protecting the enamel from plaques of fermenting carbohydrates.

FLETCHER, J. Dental Enamel: Is It a Vital Tissue? *Pub. Health* 45, 12:396 (Sept.), 1933.

How to Stop Outbreaks of Food Poisoning—Prevention of food poisoning is proposed through three channels—supervision of food handlers, more complete food inspection service, and popular education in the means of avoiding dangerous foods.

GEIGER, J. C. and GRAY, J. P. Food Poisoning. *J.A.M.A.* 101, 13:975 (Sept. 23), 1933.

Advances (?) in Cancer Control—"No marked progress has been made in instituting surgical treatment in the course of malignant disease of the breast. The present clinical methods are inadequate to detect malignancy until it is fairly well advanced." This gloomy beginning to the summary of an excellent paper on cancer of the breast emanating from the Mayo Clinic

would provide food for thought for health workers.

HARRINGTON, S. W. Diagnosis and Treatment of Lesions of the Breast. *Am. J. Cancer* 19, 1:56 (Sept.), 1933.

Tonsillectomy and Immunity—Tonsillectomy has no marked effect on the susceptibility to scarlet fever within 6 months, conclude the authors who Dick-tested the tonsillectomized children "before and after."

KERESZTURI, C. and PARK, W. H. Effect of Tonsillectomy on the Development of Immunity to Scarlet Fever. *J.A.M.A.* 101, 10:764 (Sept. 2), 1933.

Finding Tuberculosis in Children—Clearly presented is this outline of the program for detecting tuberculosis in childhood, which the author concludes is well worth the effort, difficult as it is. The details of this community case-finding program are set forth in a committee report published this month by the National Tuberculosis Association entitled "Procedure for the Discovery and Care of Tuberculous Children." An eminently sound proposal which should be known to all health workers.

KLEINSCHMIDT, H. E. Tuberculosis in School Children. *Pub. Health Nurs.* 25, 9:474 (Sept.), 1933.

How to Overcome Fatigue—This exposition of the physiology of sleep is so readily comprehensible that it seems much too clear and plausible to be entirely true. Its lesson should be taken to heart by all workers in health.

LAIRD, D. A. Fatigue. *Am. J. Nurs.* 33, 9:835 (Sept.), 1933.

When Children Grow—Statistically significant differences in annual weight increments are observed in young children living under normal conditions. In

this 8-year study, 1924 was a poor year while 1926 was the best. Guessing the reasons should prove a fertile field for cogitation.

PALMER, C. E. Variations of Growth in Weight of Elementary School Children, 1921-1928. *Pub. Health Rep.* 48, 33:993 (Aug. 18), 1933.

Pros and Cons of Poliomyelitis Prophylaxis—Balance and tolerance mark this discussion of the prophylactic treatment of poliomyelitis cases. Although there is no proof of the efficacy of adult and convalescent sera after the manifestations of the preparalytic stage,

we should not be deterred from further attempts to help cases with antisera.

WESSELHOEFT, C. The Present Status of Serum Treatment in Acute Poliomyelitis. *J. Pediatrics* 3, 2:330 (Aug.), 1933.

Will Sterilization Prevent Mental Deficiency?—Casting doubts on many of the benefits that proponents claim will follow sterilization of mental defectives is a favorite sport. These doubts are well cast in so far as most of the named premises and conclusions are concerned.

TURNER, F. D. Mental Deficiency and Sterilization. *Med. Off.* 50, 12:121 (Sept. 16), 1933.

NEWS FROM THE FIELD

NATIONAL CAMPAIGN RALLY FOR PRIVATELY SUPPORTED WELFARE WORK IN CHICAGO

OCTOBER 30 was the day set for the national campaign rally in Chicago of all communities raising funds for welfare work. One hundred and two cities between that date and November 20 will go out to raise \$53,651,210, according to an announcement made by Newton D. Baker, chairman of the 1933 Mobilization for Human Needs.

Large cities putting in welfare campaigns within this period are Chicago, Ill., with a goal of \$4,000,000; Cleveland, Ohio, \$3,985,000; Detroit, Mich., \$3,000,000; Kansas City, Mo., \$1,300,000; Los Angeles, \$2,954,648, and San Francisco, Calif., \$1,945,000; Minneapolis, Minn., \$1,650,000; Philadelphia, \$6,000,000, and Pittsburgh, Pa., \$2,500,000; New York, N. Y., \$8,600,000.

Mrs. Franklin D. Roosevelt, chairman of the National Women's Committee of the Mobilization, will preside at two of the large sessions.

Speakers on the program include Mrs. Franklin D. Roosevelt, Miss Jane Addams, Newton D. Baker, Harry L. Hopkins, Federal Relief Administrator, and John Stewart Bryan, president of Community Chests and Councils.

ANNUAL SAFETY CONGRESS

SOME 5,000 safety delegates met in Chicago early in October at their 22nd Annual Safety Congress and Exposition to formulate plans for the prevention of accidents in all fields during the coming year.

The following officers of the National Safety Council were elected during the Congress:

President, John E. Long, The Dela-

ware and Hudson Railroad Corporation, Albany, N. Y. *Managing Director*, W. H. Cameron, Chicago, Ill. *Treasurer*, W. E. Worth, International Harvester Co., Chicago, Ill.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

AT the annual meeting of the Association of Military Surgeons of the United States, held in Chicago September 25-27, Major General Harry L. Gilchrist, of the U. S. Army, was elected President. He will assume office as President of the Association January 16, 1934.

WELLCOME PRIZE AND MEDAL

THE Wellcome Prize, consisting of \$500 and a gold medal, for 1933 was awarded to Major Edgar Erskine Hume, F.A.P.H.A., Librarian of the Army Medical Library, Medical Corps, U. S. Army, for his essay "The Value of Studies in Health and Sanitation in War Planning."

CONNECTICUT PUBLIC HEALTH ASSOCIATION

THE Connecticut Public Health Association met on September 28, in Charlotte Hungerford Hospital, Torrington, Conn., where some interesting papers were presented. The attendance was 230, and the state was widely represented. Dr. Buck, of the A.P.H.A., spoke on the Chamber of Commerce Health Conservation Contest.

NATIONAL NEGRO HEALTH WEEK CONFERENCE

THE Annual Conference of the National Negro Health Week, sponsored by the National Negro Health Movement, was held October 25

in the auditorium of the new building of the U. S. Public Health Service, Washington, D. C.

NEW YORK SEWAGE WORKS ASSOCIATION

THE New York State Sewage Works Association had its fall meeting at White Plains, N. Y., October 27-28. Papers were read by Lawrence Luther, W. J. Scott and W. W. Young.

HEATING AND VENTILATING EXPOSITION

THE Third International Heating and Ventilating Exposition sponsored by the American Society of Heating and Ventilating Engineers, is to be held at Grand Central Palace in New York, February 5-9, 1934.

Air-conditioning will be especially featured, as will refrigeration in its relation to the conditioning process and equipment.

DEATH

J. WALDO SMITH, member A.P.H.A., noted consulting engineer who built New York City's \$185,000,000 Catskill water supply system, died October 14. He was 72 years old. He was well known for the construction of a 14-foot tunnel under the Hudson River, through granite at 1,114 feet under sea level, to complete the aqueduct for bringing water into the city from the mountains.

PERSONALS

MINNIE STROBEL, member A.P.H.A., has resigned as secretary of the Missouri Public Health Association. Ross L. Laybourn will serve as secretary.

DR. MAYSIL M. WILLIAMS, member A.P.H.A., formerly director of the division of child hygiene in the North Dakota State Department of Public Health, has been appointed State Health Officer. She succeeds Dr. Arthur A. Whittemore, member A.P.H.A. The appointment was made by the Public Health Advisory Council, a new body created by recent legislation.

DR. W. W. COUNCIL, member A.P.H.A., of Juneau, Alaska, has been appointed Health Commissioner of the Territory of Alaska, succeeding Dr. Harry C. DeVighne.

CONFERENCES

November 3, Mid-year Meeting of the New York State Association of Public Health Laboratories, Albany, N. Y.

November 13, Southern Branch, A.P.H.A., Richmond Va.

November 14-18, Southern Medical Association, Richmond, Va.

February 5-9, 1934, Third International Heating and Ventilating Exposition, Grand Central Palace, New York, N. Y.

Spring, 1934, Statistical Conference, International Statistical Institute, London, England.

March 29, 30, 1934, Annual Meeting of the American Association of Pathologists and Bacteriologists, Toronto, Ont., Canada.

April, 1934, Southeastern Section, American Water Works Association, Augusta, Ga.

May 9-12, 1934. Sixty-sixth Annual Meeting of the Dental Society of the State of New York, Buffalo, N. Y.

July 24-31, 1934. Fourth International Congress of Radiology, Zurich, Switzerland.

1935, International Congress on Mental Hygiene, Paris.

The Physician and Public Health Officialdom*

MORRIS FISHBEIN, M.D.

Editor, Journal of the American Medical Association, Chicago, Ill.

THE physician is, for most people, still the key-man in all matters affecting health. From the earliest times he has offered, for those whose confidence he held, the last word concerning death and disease. The aphorisms of ancient sages invariably affirm this fact. The texts of Hippocrates are as much concerned with the prevention of disease as with its diagnosis and treatment.

The vast majority of medical practice is individual. It concerns the diagnosis and the treatment of ailments which affect the individual human being. Perhaps the outstanding fear in relationship to disease is the fear of pain. Pain is a subjective sensation affecting individuals and not masses of men. Before the bacteriological epoch in medicine physicians were little, if at all, concerned with disease as it affects masses of mankind. However, the establishment by Pasteur of the germ causation of disease brought to light knowledge of the dissemination of infectious disease. This new information took the preven-

tion of some infectious diseases out of the hands of the physician and placed it in the hands of the community. This was logical, since it was by and through the community that the disease was spread, and since it was more feasible to prevent disease by and through the community than through the individual.

A large part of this problem has, of course, been associated equally with the change from rural to urban methods of living. The individual who lives alone; who obtains his food from the soil surrounding his cabin, his water from a deep spring at his door; and whose only contacts are with the members of his own family, is less likely to suffer contagious or infectious disorders than the one who is housed in one of these great barracks, called by courtesy "apartment houses," who obtains his milk from a farm hundreds of miles away, the milk having passed through the hands of innumerable carriers and processors before it reaches him; who travels daily to his office in a crowded public conveyance; who seeks his amusements in crowds of thousands in movies and tens of hundreds of thousands in baseball and football games; and whose food comes from four corners of the world,

* Read before the Health Officers Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

through the hands of many men. Such an individual is constantly affected so far as disease is concerned by his contacts with those about him.

Thus new knowledge of infectious diseases and their modes of transmission has emphasized the work of the public health official. Health departments became at once responsible for pure water supplies and pure milk supplies, for the disposal of sewage, for the control of foods, and for the study and control of food handlers. The development of the knowledge that tuberculosis might be spread by contaminated sputum spread carelessly about in public places, the knowledge that water from a contaminated well might bring on in the community a devastating typhoid epidemic, the knowledge that an infected milk supply might mean thousands of cases of septic sore throat, made the public aware of the fact that it needed the protection of its health against careless and irresponsible members of the community. Health officials were given police powers for controlling those who too lightly carried their individual responsibilities. Most of us can remember the time when the public health official was more a policeman than a scientist; when he travelled about with a club and a star forcing the closing of wells, forcing the straining and pasteurization of milk, forcing isolation and quarantine for infectious diseases.

Gradually, in connection with the development of our knowledge of immunity, came the possibility of immunization against infectious diseases of various types. Before immunization could be applied on a mass scale to human beings, it became necessary to teach them the importance and significance of these measures. The campaign for vaccination against smallpox, the first of the important measures for immunization, was not difficult in its early stages, primarily because the vast

majority of human beings feared smallpox more than any possible results that might come from vaccination. Fear is for most human beings a compelling motive. Once the nations of the world realized the value of vaccination against smallpox, it was not difficult to obtain in most countries legal measures to make vaccination against smallpox compulsory. It is perhaps significant that in the United States today our incidence of smallpox, because of the number of the unvaccinated, is far greater than that of many other civilized countries. The reason lies no doubt in the fact that smallpox has been brought largely under control by rather general vaccination and compulsory quarantine. There are philosophers among us who feel that it might be worth while to relax our efforts temporarily in order to strike fear again into a generation that is unaware of the lesson of the past. In times of epidemic when fear again strikes a community, it is not difficult to secure vaccination of vast numbers of people, whether by officials of departments of health, by industrial physicians, by school physicians, or by individual practitioners.

There are, however, new procedures in immunology of which the public is not yet aware. One of the problems of those interested in public health including both physicians and the public health officials is the means of impressing on the people the importance of immunization. Coincidental with the rise of our knowledge of the prevention of disease has come a tremendous advance in methods of educating the public. The travelling quack of an earlier day would speak at night to a few hundred people who surrounded his wagon on some city lot. In the course of some years he might have visited several hundreds of cities. The charlatan of today is bound by no such limitations. He reaches his public through all the means of dissemination of

knowledge that have been developed—the radio, the newspapers, the periodical, the direct-by-mail circular, the public address, and similar devices. These enable one who has a message to reach millions of people at a single time. Many officials in the field of public health have learned to avail themselves of these devices for the education of the public. For this purpose also new methods of education have been developed. The demonstration clinics are a practical lesson in medical methods. Their purpose is to educate the public in the value of some method in order that thereafter the public may go directly to the medical profession to obtain such service.

Whereas the prevention of disease two centuries ago was a matter between the physician and his patient, today the prevention of disease is a tremendous industry embracing the services of hundreds of thousands of persons, embracing knowledge derived from all of the special branches of science known today. The engineer, the biologist, the laboratory diagnostician, the educator, the physician, the physicist, and the chemist, all combine to make available information from their sciences for the public good. When such coöperative knowledge is required there must obviously be some center as a common meeting place, some headquarters for the placing of apparatus and materials, some executive head for coördination of effort and application of results. This obviously is the public health office of today. It would be apparent to anyone that the individual physician cannot in every community undertake to make available for disease prevention and its control all of the services that have been mentioned. The duty of the public health official in this connection is clear.

Where then does the cleavage come? How are the duties, the obligations and the prerogatives of the physician in the field of public health to be separated

from those of public health officialdom?

It is conceivable that a complete application of the mass handling of man might make it possible, even though not desirable, that all of the care of the sick and the prevention of disease among the well, be turned over to some official authority. This, which would represent the complete application of state medicine, is, I believe, recognized by all but a few fanatical adherents of the handling of men in a mass to be a most undesirable situation—one likely to result in nothing but ill for the human race. As long as human beings have individual minds and individual bodies with different constitutions, their happiness will not tolerate any such total disregard of their individualities. However, as has already been shown, there are certain aspects of disease prevention which the individual cannot undertake for himself and which must inevitably be assumed by public authority.

The family physician is so called because he concerns himself with keeping intimately in touch with all of those aspects of the lives of his patients in their families that may be concerned with health and disease. More and more emphasis is being placed on constitution and heredity as significant factors in the incidence of disease. It is known that man's resistance to disease depends as much on the quality of his constitution as on his opportunity to come into contact with infection. It is known that there are many disorders which tend to appear in families, of which no doubt the allergic and arthritic types of disease represent the most frequent forms. It is known that some families tend to be hypertensive, all having high blood pressures, and other hypotensive. The physician who has cared for grandparents and for parents knows what to anticipate in the children. The physician who has himself witnessed the birth of a child, who has

followed it through the first year of life, knowing the manner of its feeding and its nutrition; the physician who has taken the child through the various vicissitudes of childhood and adolescence, including all of the common contagious diseases; is far better able to judge the severity of the diseases that come on in middle life than one who sees his patient for the first time.

Many a physician today continues to combine those functions of priesthood and healer which were combined in the vocation of physicians in prehistoric times. Why then should any public health officialdom attempt to take from this family doctor the responsibility for individual prevention of disease that resides in the administration of preventive vaccination against smallpox, preventive inoculation against diphtheria or scarlet fever, or any of the other infectious diseases? Why suggest, as has already been done, that periodic physical examinations are best made by health departments or commercially organized groups? Why should public health officialdom assume that it is better to have children examined prior to their entrance into school in a large clinic under the supervision of the clinic head, or in a school clinic under the supervision of a salaried employee, than in the office of the individual physician? The cursory examination made available in such mass application of the ideals of preventive medicine cannot begin to compare in efficiency or in usefulness for prevention of disease with the type of study made by the individual physician in his office or in the patient's home. Obviously the factor which most concerns the socially minded leaders in the field of public health is the factor of expense. Public health officialdom recognizes that it is possible to examine a large number of children routinely at a smaller expense than the same procedure would cost if made in the physician's office. Nevertheless,

even though the individual examination costs more, it is worth more. Further, the more that such procedures are delegated to official agencies, and the more people come to believe that medical care in whole or in part is the function of the state, the sooner will we approach that period when an attempt will be made to delegate all medical care to state agencies.

No doubt the charge that is frequently made that it has been necessary for public health officialdom to take over the field of preventive medicine because physicians have neglected this aspect of their work, is made with some foundation. During the period of inflation, in the seemingly golden years of 1928 and 1929, few physicians were greatly concerned with problems of preventive medicine. When urged to examine the well, they were likely to say that practically all of their time was occupied with the care of the sick. It is reasonable to believe, however, that one of the benefits of the present period of financial depression is the realization in the minds of most physicians that they must practise preventive medicine increasingly in the future if they are not to lose the practice of curative medicine. Physicians of the past have been too readily content to leave all of the practice of preventive medicine to public health officials and to take it for granted that the duties of the public health department were being satisfactorily performed.

It is an aphorism that the bureaucrat invariably grasps more and more in the way of duties and obligations, knowing that his advancement depends largely on the expansion of his office. Thus when money is available the budgets of bureaus of all types expand constantly. It is with the greatest of difficulty that they are decreased in times of financial depression. Here again the financial depression may be said to have resulted in beneficial effects

in that it caused most public health officials to take account of their budgets, to study the expenses of their departments, and to limit their services to well established, essential public health procedures which could not be properly handled in other ways.

As budgets began to be restricted, public health officials began to discontinue many of the proper functions of the medical profession which they had taken over. Some exuberant child welfare departments fell by the wayside; school clinics for treating disease and for removing tonsils and adenoids in wholesale lots, began to disappear; house-to-house canvasses for all sorts of interesting investigations were temporarily postponed. More and more public health officials began to depend on their educational functions to enlighten the public as to the possibilities of preventive medicine, and to urge people to go to their family physician for such individual preventive medicine as these family physicians could well practise.

While it was no doubt the exigencies of the situation that compelled many public health departments to modify their functions in this manner, some enlightened health commissioners had already foreseen the possibilities. In Detroit particularly, Vaughan had realized the necessity of drawing the physician more and more into public health work. Today the so-called Detroit Plan is being accepted by both physicians and public health officials as probably the ideal method for securing a coöperative effort leading to the control of a specific infectious disease. Briefly, the plan inaugurated in Detroit in 1928 involves the participation of the general practitioner in public health procedure. Under this plan, patients are urged to go to their own doctors for preschool examinations and for immunization against diphtheria; and funds are paid from the health department to individual physicians for carry-

ing on this preventive medical work. Among the beneficial outcomes have been the reduction of diphtheria to one-fourth the incidence prior to the campaign, a changed attitude of the public toward the health department, and elimination of much antagonism by the medical profession toward the work of employees of the department of public health.

The plan has provided an opportunity for the general practitioner to review his knowledge of infectious disease and to obtain additional information through postgraduate conferences with health officials on the control of communicable diseases. By this enlistment of coöperation the office of every physician is made an educational center, a place to which mothers may come in order to obtain simple inoculation against diphtheria, but in which at the same time they learn the value of physical examinations, the importance of taking care promptly of preventable defects, and the significance of proper hygiene and nutrition. Perhaps, most important of all, people may thus be impressed directly with the desirability of having early competent medical advice in care of all types of disease.

Throughout the country there are many physicians who already have realized the importance of such preventive medical activities on the part of the family practitioner. Thus in Maryland one family doctor requested and secured from the Health Department the printed literature and forms designed to assist in teaching parents the necessity for diphtheria prevention. In 8 months he completed toxoid inoculation of a total of more than 180 children in his own family practice, and at the time of writing had given the first dose to 95 more children. During the same period other physicians had inoculated 526 children according to the records of the department.

In these times it would be well if

every leader in the field of public health would ponder carefully an address made by Sir Josiah Stamp, an eminent British authority in the field of economics to a recent congress on economic problems. He concerned himself with the "Economic Test of the Limits of Public Health."¹ After all, the money available to any community for public health purposes must be balanced against moneys needed for other causes. So intimately is health bound up with food, fuel, housing, safety and similar problems, that every executive and administrator must consider all of these objectives in apportioning the items in his budget. A free clinic for the treatment of venereal disease is no doubt a handsome appurtenance to every civilized community, but everyone will grant that the feeding of starving children should take precedence. Daily sprinkling and sweeping of all city streets would be esthetically desirable even though impossibly costly, but bacteriologic control of water supply and sanitary disposal of sewage are absolutely necessary for the continuation of life. A radio in every room in the hospital will help to free the hours from care for a good many sick people, but if the employment of a radio technician, and the purchase and upkeep of the equipment takes the place of providing a resuscitation apparatus in the operating room, it may well be avoided.

A distinguished leader in the field of public health has urged that it is uneconomic to turn over any of the functions of full-time health departments to medical practitioners. Nevertheless, one must in these times of stress and turmoil reevaluate all types of public service. The medical profession is reevaluating the methods and procedures used in the diagnosis and treatment of disease with a view to limiting their practices to the items that are essential. Similarly public health departments must reevaluate their services

to include the essentials so far as concerns prevention of disease among the public as a whole, and leave to the medical profession the practice of preventive medicine as it concerns the individual. Since the report of the Committee on the Costs of Medical Care has been gradually languishing into innocuous desuetude the trend of both preventive and curative medical practice has been toward greater individualization in the diagnosis and treatment of disease.

It is not only in the field of medicine that problems have arisen in these times relative to the manner of conduct of human affairs. Attempts are being made in every industry and business to bring some order out of the chaos into which the machine age, mass methods of living, and the work of the so-called efficiency engineers have brought us. Those who have witnessed at first hand the efforts that have been made during the last decade to bring out of the involved situation that exists in the care of the public health, some definite order, will recognize the necessity that exists for establishing more definitely the line of relationship between official and non-official health agencies and the medical profession. If one were at this time to seek the primary disturbing factor in the situation it would undoubtedly be the last mentioned group—namely, the nonofficial health agencies. One is concerned here as in the field of medical education with what has been aptly called "the curse of philanthropy." Since the time when the Rockefeller millions were first placed at the disposal of the International Health Board, medicine has been peculiarly the pet of philanthropy. In various surveys of philanthropies and foundations, this fact has been clearly established. Billions of dollars have been placed at the disposal of various funds and foundations for the investigation of problems in the field of medicine and for prevention of disease. It would be

unreasonable to conclude that all of this money has been wisely spent. Indeed it is possible to show beyond any shadow of a doubt that many millions of dollars have been wasted. Moreover, there is adequate evidence to indicate that meddlesome interference in the conduct of public health work by these nonofficial agencies has in some parts of the country completely disrupted public health departments; has brought about intense antipathies between physicians and public health officials who must obviously work in the closest harmony to secure the best results; and, on other occasions, has made the care of the public health a football of politics.

As has been said previously, much, if not the greater part, of our knowledge in public health during the last 50 years has been the result of movements initiated in communities by physicians and carried forward by physicians until the time when they had achieved sufficient force and volume to demand the creation of special departments or bureaus for their control. Many of the discoveries on which preventive work is based were contributed by physicians. Doctors conceived the antituberculosis movement; medical societies in many instances petitioned state legislatures for the creation of state boards of health; the medical profession has initiated in the past and continues to propose constructive legislation for the public health.

The medical profession has not been content with raising the standards of medical education, improving the quality of proprietary medicines, fighting quacks within its own ranks as well as without, and aiding in the development of the modern hospital; but has taken an active part in creating organizations, both governmental and voluntary, designed to improve the public health. Then, unfortunately, it has too often allowed these organizations to be-

come alienated from medical guidance and advice. In consequence, some workers in the field of public health have forgotten or overlooked the importance of the medical profession. They have designated themselves as specialists and their field of endeavor as a specialty, but they have failed to recognize that public health is a specialty of medicine. True, a well-rounded public health program requires nurses, engineers, technicians, and educators; but all these must be guided by underlying medical principles. Significantly, perhaps partly as a result of economic stringency, now that adequate budgets are hard to get and public services which have been regarded as essential because long established are threatened, workers in public health are turning back to the medical profession.

The medical profession has always stood, and still stands, in favor of public health work of the right kind, properly conceived, correctly organized, and competently directed, for the better health of the community. The medical profession does not feel obligated to endorse unwise, visionary, or inefficient projects merely because they are launched in the name of the public health. Because it does not hesitate to speak out against abuses, it has been unjustly accused of obstructing progress. But all motion is not necessarily progressive. In times of economic stress, public health work is of special importance. If epidemic scourges such as typhoid, diphtheria, yellow fever, malaria, and smallpox, held in check by preventive measures, were to be added to our financial difficulties at this time, the result might well be disastrous. The absence of epidemic plagues has been one of the principal contributing factors to low depression death rates.

The physician of the future must be increasingly a practitioner of preventive medicine. Obviously this involves new relationships to the public and to the

health official. Under various forms of state practice, problems have arisen which were discussed by Sir George Newman, K.C.B., M.D., F.R.C.P., chief medical officer of the Ministry of Health, who in his capacity as president addressed the Section on Public Health at the centenary meeting of the British Medical Association." He pointed out that in no previous age has there been such growth of the conception of preventive medicine as in the present era, paying tribute to Bright, Addison, Hodgkin, Gull, Jenner, Osler, Allbutt, and Barlow for the constructive service that has been rendered in the great march of preventive medicine by medical practitioners. "It is they," he said, "who have made the bricks, found the road, explored the facts, carried on the fight, and educated the people in a way of life." He elucidated further: "They searched into the circumstances of disease and related it to environment; they introduced medical notification and hospital isolation; by their investigation of factory conditions they initiated industrial welfare; they stemmed the rising tide of spirit drinking; they began the reformation of midwifery and were the first to attack the problems of child sickness and mortality; they established dispensaries and staffed the new hospitals; their systematic support of vaccination instituted the practice of immunity; and their scientific observation was the beginning of British epidemiology."

If one were to seek any gross division of obligations and prerogatives as applied to the relationship of the physician and public health officialdom to the problem of preventive medicine, the line of demarcation most apparent is that between procedures applied to the individual and those applied to the community. Problems of both preventive and curative medicine as they affect the indigent must perforce be community problems. Yet even these

may well be handled individually by physicians when they concern individual human beings, leaving it to the community, as is already done in many places, to provide the means. Under such a gross demarcation any form of preventive inoculation should logically be referred to the individual practitioner, except in times of epidemic when compulsory inoculation might have to be carried by the State. Under such a demarcation, periodic physical examinations, including not only the examinations of adults but also pre-school and school examinations of children, would also be assigned to the family doctor, whereas by contrast special examinations for industry, special examinations for army, navy or other public appointments, and the examinations of food handlers might well come within the purview of a department of health. Even in the case of food handlers, however, a suitable system of certification in which the employer would be made responsible for maintaining the good health of his employees might work out more satisfactorily.

As has been mentioned, isolation and quarantine, sewage disposal, control of milk, water, and food supplies generally, ventilation of public buildings, and all of those aspects of preventive medicine included under sanitary engineering, would come logically under the auspices of the department of health.

There is one aspect of the work of the departments of health which has been largely developed within the last 10 years and which must increasingly become a function of any well organized department. I refer, of course, to education of the public in elementary personal hygiene, education of the public as to basic facts in the diagnosis of diseases and the fundamentals of good medical care. Some of the departments of health in our large cities and some of the state departments of health which

are most progressive have already developed these functions to a point which constitutes an adequate demonstration of the merits of this phase of their work. On the other hand, a great many departments have lagged behind or have embarked on such amateurish attempts to utilize public education and information as to open themselves to ridicule by those competent in this field. Unless means are found for suitably educating and developing an adequate personnel for this purpose the time may yet come when great departments of health may find it necessary to engage the talent of advertising agencies, of writers and publicists, as well as other professional persons, to develop suitably this phase of their work.

It is significant that the American Public Health Association itself has

realized the importance of this new function, and that it has created special sections for their discussion in its annual sessions and a special department in its *Journal* for the promulgation of methods and ideas. It is obvious that the individual physician may be to some extent a competent educator of his individual patients, but it is equally obvious that he cannot carry daily and constantly to the vast majority of people the amount of health information that can be put forth by an active and competent department of health.

Children's Weight During Economic Disturbances

A STUDY on School Children in Hagerstown, Md., conducted (1) each year between 1921 and 1927, and (2) in May, 1933, gave the following results:

1. Average weight of children in the two periods presents no consistent or statistically significant differences.

2. The variability of body weight (measured by the standard deviation) is not, for boys, consistently different for the two periods. For girls, body weight is slightly more variable in 1933 than in 1921-1927.

3. In the totals of 1,245 boys and 1,269 girls weighed in 1933, there are 4 fewer boys and 41 more girls who are 12 per cent or more below average weight than would be expected had the same proportions been underweight as were found in the 1921-1927 period.

From these findings it may be concluded that there is substantially no change in the weight of boys, and a slight increase in the number of underweight girls, during the last few years of the economic depression.

Hagerstown is not representative of the most severely stricken type of community. It is a typical small urban community which is now suffering distinct, though moderate, economic disturbances and is fairly representative of communities in which 20 million people, or nearly 15 per cent of the population, live.—Carroll E. Palmer, M.D., Consultant in Child Hygiene, U. S. Public Health Service, *Pub. Health Rep.* 48, 12 (Oct. 20), 1933.

Proposed Federal Food and Drugs Act Its Public Health Features*

WALTER S. FRISBIE, F.A.P.H.A.

*Chemist in Charge of Coöperation, Food and Drug Administration,
U. S. Department of Agriculture, Washington, D. C.*

IN order to appraise intelligently the health protective features of the legislation now before Congress, it is essential that they be compared with such features as are embodied in the present Federal Food and Drugs Act. Under this law, food is declared to be adulterated if it contain any added poisonous or deleterious substance which may render that article of food dangerous to health. The commerce in food which is deemed to be filthy, decomposed, or putrid, is also prohibited. The act further declares food to be adulterated if it is the product of a diseased animal or one that has died otherwise than by slaughter.

In the field of drugs and medicines, the health protection afforded may be said to be indirect rather than direct. The law requires that official Pharmacopœial and National Formulary preparations shall conform to those standards or be labeled to show wherein they differ. False and misleading statements as to the ingredients of drugs are prohibited, and therapeutic claims which are false and fraudulent make a violation. Cosmetics are subject to no regulation whatever at the present time so far as interstate commerce is concerned.

Turning now to the proposed new act, identified as S. 1944, and intro-

* Read before the Food and Nutrition Section of the American Public Health Association, at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

duced by Senator Copeland last June, we find a number of very definite health measures not included in the present law. In the first place, all of the valuable provisions of the present law, whether from the health or economic viewpoint, have been retained. In the case of food, we find these supplemented, so far as public health is concerned, in the following particulars. Food is adulterated if it is or may be dangerous to health. Certain species of fish and some shellfish, such as mussels, are naturally poisonous, and a few varieties of beans, although generally foreign grown, contain dangerous amounts of a cyanogenetic glucoside. Such foods at the present time are not in violation of the act although obviously dangerous to health. The bill would give jurisdiction to the Department to regulate the type of containers used for food prohibiting such as might render the contents injurious to health.

As an example, we may cite the use of collapsible lead tubes for fish and cheese preparations, as well as the lead foil frequently used to wrap cheese, candies and similar articles. In the case of confectionery, resinous glazes and non-nutritive substances are definitely forbidden. The latter is of particular importance in view of the tendency on the part of certain manufacturers of novelty candies to incorporate metallic trinkets, marbles, coins, and similar articles to increase sales.

Some of these are made of lead and contaminate the candy even when the article itself may have been removed. Hard substances concealed or partially concealed are, of course, likely to injure the teeth or become lodged in the respiratory tract of children. A recent court decision averred that the present act does not forbid the addition of such substances to candy.

The present act is silent with respect to the sanitary conditions of establishments where food is prepared or manufactured for interstate shipment. The new bill states that food which has been prepared, packed, or held, under insanitary conditions whereby it may have been contaminated with filth shall be deemed adulterated. These sanitary provisions are supplemented by a special paragraph relating to conditions of manufacturing, of processing, and of packing. While the authority of this section extends to drugs and cosmetics, it is perhaps particularly pertinent in the case of food. The substance of this provision is to the effect that where conditions surrounding manufacturing, processing, or packing are such that the product may be injurious to health and its injurious nature cannot adequately be determined by objective examination, the Secretary of Agriculture is authorized to require such manufacturers or packers to obtain a permit. Such permit may be obtained only on compliance with regulations which the Secretary is authorized to promulgate. The period during which permit or licensed operations shall be required is optional with the Secretary, who is also authorized to suspend immediately any permit where the conditions of its issuance have been violated. There are certain operations in the food field to which this permit system is peculiarly appropriate.

This Association is fully aware of the repeated instances of food poisoning which have been traced to infected cream fillings, either cream puffs, chocolate

eclairs, or cream pies. In most cases, before the bacteriological evidence as to the causative agent has been obtained, the offending article of food has been distributed with probable increased incidence of food poisoning. A similar situation is reflected in the commercial preparation of fresh crabmeat, that is, fresh, cooked crabmeat, packed in containers which are not hermetically sealed and processed. Other varieties of shellfish may be subject to contamination either through polluted growing areas or as a result of insanitary preparation. The difficulty and delay incident to the confirmation of its dangerous character through objective examination is at once apparent. Where careless or indifferent methods are known to prevail in the handling of foods, such a permit system obviously constitutes a real public health safeguard.

It may also be of interest to mention the fact that the new bill provides for the use in foods of only such coal tar colors as have been certified by the Secretary of Agriculture. Especially noteworthy is the language of the section which provides for administrative findings of safe limits for such toxic substances as may unavoidably be present in food. The Secretary of Agriculture, after due notice and hearing, may either prohibit such substances or establish tolerances when he finds "that the presence of an added poisonous or added deleterious substance in or on food or cosmetics is or may be injurious to health, taking into account other ways in which the consumer or user may partake of or be exposed to the same or other poisonous or deleterious substances, . . ." In other words, the Secretary shall not only take into account the toxicity of the added substance, *per se*, but the probable effect of this ingredient after considering all of the other public health factors involved. The authority to establish

tolerances includes cosmetics as well as foods.

The adulteration of drugs is defined essentially as under the present act except in one very important particular. The terms of the bill declare a drug adulterated if it is or may be dangerous to health under the conditions of use prescribed by its label. There are certain drug preparations which are actually a menace to health when used without competent medical advice. At the present time such drugs may be sold if they are truthfully labeled and bear no false and fraudulent claims of therapeutic benefit. Not so long ago the death of a prominent and wealthy citizen of this country was widely heralded in the press as one due to the indiscriminate use of a radium salt preparation. The preparation was known to the Food and Drug Administration; was not improperly labeled; and its shipment in commerce was not a violation of the present law. Under the terms of the proposed bill it would be very definitely brought within the ban of the statute.

The misbranding of drugs is more specifically covered in the text of the proposed measure. Not only is the list of narcotic and hypnotic substances supplemented by the name with such products as the barbituric acid derivatives, paraldehyde, peyote, and sulphonmethane, but there is a further requirement that in addition to the name and proportion of such substances present the label shall bear the words "Warning—May be habit-forming." This section of the bill also authorizes the Secretary to supplement this list with such other substances as he may find to possess narcotic or hypnotic properties. If the labeling of a drug bears the name of any disease for which such drug is not a specific cure but only a palliative, it shall bear in immediate connection with the name and in equal prominence a statement that the drug is

not a cure for the disease named. In the case of drugs which are liable to deteriorate, the Secretary is authorized to prescribe regulations for the packaging of such articles and for labeling to show such precautions as may be necessary for the protection of public health. A preparation which is represented as a germicide, bactericide, disinfectant, or antiseptic, must be plainly and conspicuously labeled to show exactly the method and extent of application necessary to kill active microorganisms with which the preparation comes in contact.

The question of individual susceptibility both to foods and drugs has not been overlooked in the text of this bill. Among the paragraphs relating to the misbranding of foods is one which requires that an article of food for which no definition of identity has been adopted shall bear upon its label the name of each ingredient in order of predominance by weight, exempting the specific designation of the particular spice, flavor, and artificial color. Such informative labeling is of course valuable for discriminative purchasing but most important to advise those sufferers from various types of food allergy as to the definite character of such foods as are now sold under fanciful or foreign names without disclosing the presence of substances which are responsible for the appearance of untoward symptoms in such cases. Parallel provisions are to be found in the drug misbranding section. Under this proviso any drug other than a U.S.P. or N.F. preparation is required to show on its label its common name, if such exists, as well as the presence and amount of each medicinal or physiologically active ingredient, and if necessary for the protection of public health, the Secretary may prescribe further regulations for labeling. Here again is an additional safeguard afforded those for whom certain drugs are definitely contra-indicated.

A discussion of drug regulations

would be incomplete without calling attention to the definition for drug. At the present time, the term "drug" means all medicines and preparations official in the United States Pharmacopœia or National Formulary, or any substance intended to be used for the cure, mitigation or prevention of disease. The new bill carries the same definition but supplements it in two important particulars: First, to include with substances all preparations and devices for the cure, mitigation, treatment or prevention of disease, and, second, all substances and preparations other than food and all devices as well which are intended to affect the structure of or any function of the body. Such devices as electric belts recommended for various ills and such preparations as are now offered and guaranteed safely to slenderize the human form are at the present time outside the jurisdiction of the act and their regulation is only another step to safeguard the public health.

Since the present food and drugs act is silent with respect to cosmetics, it may be of interest to note that it is proposed to define this term to include "all substances and preparations intended for cleansing, or altering the appearance of, or promoting the attractiveness of, the person." A cosmetic will be deemed to be adulterated in two instances: (1) if it is or may be injurious to the user either under the conditions of use prescribed in the labeling, or under customary or usual conditions of use, and (2) if it bears or contains any poisonous or deleterious ingredient which is prohibited or which is in excess of the limit which the Secretary is authorized to prescribe.

All foods, drugs, and cosmetics are included in the sections relating to false advertising. An advertisement of any of these commodities is false if it is untrue in any particular, or by ambiguity or inference creates a misleading im-

pression, and the term "advertising" includes all representations of fact or opinion disseminated in any manner other than by labeling. All of the injunctions respecting the proper labeling of foods, drugs, and cosmetics apply with equal force to their advertisement. In addition the bill cites a list of diseases, including appendicitis, cancer, diabetes, nephritis, tuberculosis, and venereal diseases, where self-medication may be dangerous or contrary to the interests of public health, and for these the advertising of drugs is prohibited, except where such advertising is disseminated to members of the medical and pharmacological professions or appears in scientific periodicals. The public health significance of the control of advertising, particularly in the field of drugs, should be at once apparent. At the present time there is a long list of drugs which are shipped in interstate commerce, the labeling of which is not in violation of the present Federal Food and Drugs Act, but the same preparations are extravagantly advertised in the press or by radio with a complete disregard of the falsity of the claims made with respect to the therapeutic benefit promised sufferers of these various afflictions. The power and influence of advertising is readily conceded. When such advertising relates to the food which is necessary to maintain health and to the drugs which are expected to restore it, public welfare demands that the statements made in the public press and through the channels of the radio shall be free from misleading statements in the case of food, and false or fraudulent claims in the case of drugs.

Aside from the increased penalties which have been provided there are two more sections of interest. One relates to injunction proceedings which are provided in the case of repeated shipment in interstate commerce of adulterated foods, drugs, and cosmetics,

and for the continuous dissemination by broadcast or United States Mail of false advertising of these commodities. The other section relates to publicity, and authorizes the Secretary of Agriculture to disseminate from time to time any information he deems necessary in the interest of public health or for the prevention of fraud.

In this paper an attempt has been made merely to summarize the health protective features of this new legislation. The bill contains many other valuable provisions which are not to be found in the present act, all of which are in the interest of better consumer protection. The bill has been termed a consumer's measure; at any rate it has

been framed with that idea in mind. It should be of especial interest to public health officials and the Department has conceived that it has an obligation to acquaint such officials and through them, so far as possible, the consuming public with the steps which have been taken in their interest.

The Department of Agriculture, through the Food and Drug Administration, will coöperate to the fullest extent in acquainting you, and through you others who may be interested, with this legislation. It expressly desires that you give the Administration the benefit of your opinion, criticism and comment on this measure and what it purports to accomplish.

Childbirth Benefits in the New Social Insurance Law, Rumania

THE law of April 8, 1933, consolidating and amending the social insurance laws of Rumania, contains much more generous childbirth-benefit provisions than the law of 1912 by which compulsory sickness insurance was first introduced in Rumania.

An insured woman is now entitled to a childbirth benefit of 50 per cent of her wages payable for 12 weeks, to treatment by a physician or midwife, and to the necessary medicines; whereas in the old law no medical treatment or medicines were provided in addition to the cash benefit, which was paid for only 6 weeks but could be extended for another 6 weeks if the woman nursed the child.

In addition to extending the duration of the childbirth benefit the new law provides a special benefit for a 6-week

period if the woman nurses the child.

Instead of the cash benefit the woman may be given treatment in a maternity clinic. During her stay in the clinic the cash benefit is discontinued, unless she is supporting her family; in that case one-half of the benefit is paid.

The new law provides for the uninsured wife of an insured man the same childbirth benefits as for a woman insured in her own right, provided her husband has paid his dues for at least 52 weeks in the preceding 2 years. If the financial condition of the insurance fund permits, the uninsured wife may be given in addition a cash benefit of 50 per cent of the sick benefit to which her husband would be entitled in case of illness.—*Monitorul Oficial*, Budapest, April 8, 1933; *Bulletin de l'Office International du Travail*, Basel, 1913.

The Roentgenogram in So-Called "Acute" Silicosis*

HOMER L. SAMPSON

Director, X-Ray Laboratory, Trudeau Sanatorium, Trudeau, N. Y.

THE recent literature contains several references to an acute form of silicosis. In dealing with a disease which is by definition chronic in its course, the designation "acute" is ambiguous, but it has been employed to indicate that the process develops within a period of a few months or years. It has been my privilege to examine a series of roentgenograms of persons said to be suffering from this condition. One set was from a small group of sand blasters and another from a group of colored laborers who had been engaged in the boring of a tunnel through rock of a very high silica content. Some of these persons have died and were autopsied. The pathological aspects will be illustrated by Dr. Gardner, while I will attempt to describe the roentgenograms in the living members of the group.

Before considering the roentgenological appearances of this disease, it is of prime importance to consider the roentgenologic technic. In an acute silicosis we would presumably be dealing with deposit in the lymphatics and regional lymph nodes of particulate matter which is capable of provoking an acute reaction in these tissues. We have reason to assume that in the early phase of the disease the physical changes in the lungs would be so slight that they would not produce recognizable shadows. To demonstrate such minute changes it is necessary to give especial

attention to the factors involved in the making of the roentgenograms. I do not hesitate to say that stereo-roentgenograms are necessary if we are interested in the early manifestations. With properly taken films, one can, in the interpretation, eliminate disturbing extrapulmonary shadows and also evaluate slight intrapulmonary variations due to movement. The X-ray tube should be of the line-focus copper-backed-target type, with a focal spot not greater than $10/64''$, the tube-film distance not less than 4' and the time of exposure (which should be carefully checked) not slower than $1/10$ sec., or preferably $1/20$ sec. Longer exposures permit of too much movement of the intrapulmonary shadows. Obviously there are many other factors which, if neglected, will make interpretation more difficult. These are too numerous to mention. Probably the most important is the blur due to screen-film contact and movement. All of these factors are specifically mentioned because of the fact that a larger focal spot, a longer exposure time, and a shorter distance, may produce variations in the shadows that can be very misleading.

In considering the very slight alteration in the pulmonary field which such insignificant anatomical changes produce, one must bear in mind certain manifestations of the normal chest: The movement of the pulmonary markings at the left base due to the heart beat may well be mistaken for the

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

cloudiness expected in early silicosis. Similarly the shadow of the margin of the pectoralis muscle is not unlike that shadow seen in cases of beginning fibrosis. However, the shadow of the muscle is situated more peripherally and continues beyond the pulmonary field while the intrapulmonary haziness of silicosis is usually more centrally located. Also, in the case of the pectoralis muscle the lung markings are visible through the shadow of the muscle, whereas the enveloping intrapulmonary infiltration produces cloudiness which tends to obscure the vascular ramifications. In general, if the cloudiness, which has not yet assumed the nodular appearance, is confined to the region of the pectoralis muscle or to the left base, and if no alteration of the pulmonary pattern is seen above this level, we may not be justified in believing we are dealing with a pathological process.

Of a large series of roentgenograms of miners who have been exposed to silica for varying periods of time, in general, the shadow changes in the roentgenogram increase with the length of exposure. Roentgenograms of a certain quality or character, that is, those in which there was loss of detail due to movement, or large focal spot, or short tube-film distance, or a too contrasty film, or a combination of these, may have such a shadow complex as to be mistaken for such pathological changes that take place before obvious nodulation has appeared.

After the stage of nodulation has been reached it is not difficult to recognize the characteristic mottling. If we are to be guided by experience in other acute pulmonary diseases, that is, pneumonia or pulmonary tuberculosis, we have reason to believe that in "acute" silicosis, serial roentgenograms taken at short intervals will or should show obvious changes in the shadows during the period of progression. Monthly roentgenograms should reveal

a rapid increase of shadows until the climax is reached, when the process should pass into the chronic stage, which form is now well recognized.

I think it might be postulated that if serial roentgenograms fail to reveal obvious, rapidly changing shadows, and by that is meant shadows changing from month to month or week to week, one is not justified from a roentgenological point of view, in considering a silicotic process as acute. Undoubtedly there are persons exposed to heavy concentrations of silica for short periods who exhibit various symptoms of acute disease, but the serial roentgenograms which I have seen did not confirm the diagnosis of uncomplicated silicosis.

At this juncture it is highly important to consider from a roentgenographic standpoint the presence of an infectious process superimposed upon a preëxisting silicosis, or *vice versa*. Here we have (according to the experimental work of Gardner) reason to expect reasonably rapid changes to take place in the processes. If the picture changes with extreme rapidity it is hard to conceive that these alterations are due only to the inhaled silica; it is more probable that one is dealing with a complicating infection.

In general, two types of this so-called infection picture were present in the roentgenograms studied: (1) that which resembled very closely the characteristic shadows of a pulmonary tuberculosis—in some instances even to the extent of having cavity formation and in which there was no diffuse nodulation; and (2) those which presented the above characteristic shadow-complex of a tuberculosis plus a diffuse nodulation. To this latter group might be added another type. A diffuse nodulation of a distinctly fluffy character—diffuse cotton ball appearance, unlike the longstanding nodulations of the non-infective group. The inferred infective process, in a few instances, was so advanced as

to make the interpretation of an associated silicosis uncertain. In not a few of those cases who probably had an infection it was not improbable that some had a degree of silicosis that was not yet recognizable by roentgen examination.

There is reason to expect, in any acute process, shadows of a rather characteristic nature. In practically all cases the one outstanding feature of the roentgen shadow complex is its cottony or fluffy appearance and its ill-defined margins. It is not to be forgotten that in the earliest phase of such processes, there may be no discernible shadow in the lung field. The cellular reaction may be sufficient to produce pronounced subjective symptoms, but for the time being there is not sufficient loss of air space to be recognizable on the roentgenogram. If the disease progresses this condition does not last long and the next roentgenogram of the series will show a change. I believe until serial roentgenograms reveal rapidly progressive or retrogressive shadows, and also the stigma of an infection be satisfactorily excluded, one is not justified in interpreting the roentgenogram as rapid uncomplicated silicosis.

Gardner writes "In most instances authors claim that fibrosis of the lungs

develops after a few short inhalations of dust over a period of weeks or months." Further he states that "in order to produce significant changes, animals must be exposed for periods measurable in years to concentrations of dust no heavier than those in the worst industrial condition."

In the rabbit it has been demonstrated that silicosis is a progressive disease. After 13 months of exposure the animals were set aside in a normal atmosphere. The resulting progressive changes that occurred were the development of proliferative nodules. No mention is made of acute silicosis.

Rabbits exposed to a high concentration of quartz dust for 13 months revealed at autopsy only many small proliferative nodules in and about the pulmonary lymphoid tissues. The X-rays revealed barely detectable shadows.¹

There is one pertinent point, however, that needs to be cleared up before one can exclude the possibility of acute silicosis, and that is, in many cases apparently suffering from silico-tuberculosis or tuberculo-silicosis, tubercle bacilli are not demonstrated.

Pathology of So-Called Acute Silicosis*

LEROY U. GARDNER, M.D.

*Director, Saranac Laboratory for the Study of Tuberculosis,
The Edward L. Trudeau Foundation, Saranac Lake, N. Y.*

DURING the past 3 years several reports of so-called "acute silicosis" have appeared in the literature. As far as can be learned Macdonald, Piggot, and Gilder¹ first used the term in a publication describing silicosis in young women employed for 4¼ years or less in packing soap powder. Gerlach and Gander² reported a similar condition in a German scouring powder plant and Chapman³ described its occurrence in an American factory of the same kind. These cases all developed in young women who were said to have been exposed to excessive concentrations of silica dust although no counts of the atmospheric concentrations had been made.

However, the authors were more impressed by the fact that there was free alkali dust in the air of the working places (approximately 25 per cent of such powders are alkalies) than with the high silica concentrations. They concluded that since silica is soluble in an alkaline medium the inhaled material would quickly dissolve to form colloidal silica in the moist lung tissues, and as a result the connective tissues would respond by proliferation much more rapidly than is said to be the case when pure silica is slowly dissolved by the slightly alkaline body fluids.

Kessler⁴ reported on a group of sand

pulverizers who were alleged to have developed silicosis after exposures as short as 4 months to 1½ years. These were young male negroes. It was stated that the dust concentrations were excessive although the actual figures are not available. The particles were very fine (1 to 5 microns in diameter) and over 99 per cent of them were free crystalline silica. In this group it was assumed that the rapid development of the silicotic process was due solely to the high concentration of dust in the atmosphere. Since the men had not been examined before employment in this plant, they might have had previous exposures to siliceous dust. If so, the silicosis from which they apparently suffered could not be considered acute.

The lack of complete data in these reports raises the question as to whether a chronic disease like silicosis, which in the majority of industries today requires at least 10 or 12 years for its development, and which under the very worst conditions in the past only became recognizable after 3 or 4 years, can under any conditions actually develop to a degree where it can be recognized in a roentgenogram in shorter periods of time. If it does occur, what is its character and what are the conditions responsible for the accelerated reaction? Two factors, the presence of free alkali in association with silica dust, and an excessive concentration of the silica itself, have already been suggested. A

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

third factor might be particle size, and a fourth, concomitant infection.

The author has had opportunity to study the lung tissues and in most instances ante-mortem roentgenograms from 15 persons who were said to have developed silicosis after dust exposures of from 8 to 17 months. Of these 9 were employed as laborers and drillers in a tunnel through practically pure quartz; 4 were sand blasters, and 3 were sand pulverizers from the same group reported by Kessler.¹ For the last group the occupational histories are most incomplete and probably inaccurate.

No atmospheric dust counts were available, but from all reports excessive amounts of extremely fine dust were generated in each case. In the tunnel, which was bored without effective ventilation, the men returned to the face immediately after blasting and were required to work with dry drills in an atmosphere so exhausted by gasoline engines that they must have breathed abnormally fast. Such conditions would obviously favor the inhalation of unusually large quantities of very fine dust. The sand blasters also were without effective protection; one man dated the onset of his symptoms from the bursting of a sand hose while cleaning the inside of a large tank. The sand was used over and over until it became so fine as to be no longer effective as an abrasive. In the pulverizing plant, where the sand used by the sand blasters was ground and bagged, there were protective devices but these were apparently not altogether effective. While this information implies excessive concentrations of extremely fine silica particles, the dust exposures cannot be measured quantitatively.

In none of the groups had there been any attempt to examine the men when they were employed. Therefore one is compelled to rely upon the occupational history obtained in all cases after the

development of alleged symptoms. Such information must be regarded with suspicion when claims for compensation are pending, as was the case with these individuals. Some of the information was obviously valueless, as in the case of a sand pulverizer with a roentgenogram showing widespread pulmonary disease, who had worked in the plant only 35 days. On the other hand, the age of many in these groups and the conditions under which they were hired precluded any prolonged exposure to silica in previous occupations. Five of the tunnel workmen were under 29; the others, with 1 exception, were under 40. Seven were negroes who claimed to have had no previous experience in mines. Two were white men who had been coal miners for 4 and 7 years respectively. The negroes were reported to be common laborers brought from another state under contract. Most of them were employed at times as drillers, an unusual occupation for unskilled laborers, but it was contended that professional miners would not work under the conditions existing in this undertaking. The sand pulverizers were also young negroes whose previous employment was unknown. The sand blasters were all white, aged 26, 27, and 45 respectively. This evidence for the shortness of the exposure periods is also obviously open to criticism, but even if the exposure was not so brief as claimed in some individual cases, nevertheless it could not have been as long as that in industries usually associated with a silicosis hazard.

Since information as to the exact character and duration of the dust exposure in these cases is so limited, the justification for this presentation might be questioned. Several reasons exist. In the litigation attendant upon the presentation of compensation claims many of these persons were alleged to be suffering from an "acute silicosis." With 3 exceptions these men died from

9 to 18 months after completing very short exposures to pure silica. Few autopsies have been reported upon persons dying during the course of such short, severe exposures and therefore these cases may shed some light upon the nature and extent of the silicotic reaction. While it is known that silicosis is a progressive disease, the amount of progression to be expected within so short a time after the exposures must be limited.

in many of the sections they are extremely numerous. The relative size of the nodules which had developed after various exposures could be more accurately measured. In a group of sand blasters working from 1 to 5 years the outline of the central hyaline portions of various nodules in micro-sections were drawn with a camera lucida. Figure I illustrates representative nodules from 4 different cases. After a 12 months' exposure the nodules measured from 0.3

In all cases but 1 (No. 69) there is definite microscopic evidence of silicosis consisting of characteristic hyaline fibrous nodules. These lesions are definitely smaller but appreciably more abundant than those encountered in the usual run of silicosis cases known to have had more prolonged exposures to dust. It has not been possible to count the actual number of nodules in a given volume of lung tissue, as suitable quantities from corresponding parts of the different lungs were not available; but

to 0.4 mm. in diameter; by 5 years they had attained a diameter of 0.7 to 0.8 mm. In the intervening periods of 15 and 18 months there had been an appreciable increase in size. The nodules in the tunnel workers were approximately 0.4 mm. in diameter. For comparison a few nodules from the lung of a hard rock lead miner were projected in a similar manner. These nodules, too large for illustration, measured from 3 to 4 mm. in diameter. The tracings also demonstrated that all

culosis was probably the cause although this could not be definitely proved.

The most common lesion was a diffuse caseous pneumonia without definite tubercle formation. The air spaces were filled with necrotic exudate which in occasional areas could still be identified as consisting of a mixture of mononuclear and polynuclear leucocytes. In many instances the pulmonary framework and even the silicotic nodules were involved in the necrotizing process. Frequently great numbers of cholesterol crystal clefts were observed. (The cleft was formerly occupied by a crystal which was dissolved in the preparation of the section.) In 5 instances the tuberculosis occurred in small bronchopneumonic patches with caseation scattered here and there throughout the lung. Cavity formation was observed in 2 of these cases but in the other 3 only sections of the lung were obtained without record of conditions in the remaining portions. Tubercle bacilli were rare in all instances, and in some of the obviously tuberculous lesions none could be found.

There were 2 cases (Nos. 63, 71) in which the infectious process was presumably tuberculous but a definite diagnosis could not be made. The air spaces were filled with a partially necrotic exudate and some of the silicotic nodules had a central zone of granular necrosis but neither bacilli nor typical tuberculous lesions could be discovered.

The acute and chronic non-tuberculous pneumonias were interesting. One case (No. 64) occurred in a white man with 3 or 4 years' experience in a coal mine who showed extensive silicosis of the small nodule type and considerable anthracosis. In one lung the air spaces between the silicotic nodules were overdistended with an exudate consisting almost entirely of polynuclear leucocytes with numerous pneumococcus-like organisms; in the other there was organization with extensive interstitial fibrosis and an acute exudate in the distorted air spaces. The other case (No. 34), a more acute unresolved pneumonia also occurred in a white man, a sand blaster for 17 months. His symptoms appeared at the end of this period but he worked at another job in the same plant for 17 months more before he was forced to enter a hospital. He died 4 months later. The roentgenological and pathological diagnosis at this institution was silicosis complicated by tuberculous broncho-pneumonia and right heart failure. At first sight the sections did suggest an element of tuberculosis but further study has convinced the writer that the infection was not of this character. Silicotic nodules were

embedded in areas of massive fibrosis from which most of the air spaces had disappeared or were represented by distorted slits. Other less involved portions of the lung showed air spaces with thick walls and a mixture of acute and organizing fibrinous exudate in their lumina. In still other areas edema and passive congestion dominated the picture.

The gross appearances have not been described because they were uninformative. In only 8 of the tunnel workers was the author able to see the whole lungs and in them the tissue had already been fixed in formalin; from the remaining ones large blocks of tissue were available for study. In 7 of the group caseous tuberculous pneumonia was so extensive that it obscured any other lesion which might have been present. Careful search with a lens disclosed nodules not greater than 1 mm. in diameter which suggested a complicating early silicotic reaction in 2 instances. In 2 others the diagnosis was questionable. Had the occupational histories not been known, it is doubtful whether silicosis would have been thought of in any of them. Careful inspection of the apices of the lungs failed to disclose evidence of healed tuberculous lesions, and no calcified foci could be detected in the lymph nodes.

Dr. Clayton S. Smith⁵ has analyzed portions of the lungs of the tunnel workers for silica. The complete details of his study are published elsewhere in this *Journal*, but he has permitted the author to summarize his findings in this report. He made separate analyses of various portions of each lung but in Table I his figures for each case have been averaged. The percentage of silica in the dried lung varied between 0.84 and 3.1. It was lowest in the case with no silicotic nodules (No. 69). A second case with very slight lesions (No. 66), showed only 0.875 per cent. In the others, with variable amounts of reaction, it ranged between 1.24 and 3.1, but the amount was not proportional to the period of

employment. The highest figure occurred in a man with 3 or 4 years' previous employment in a coal mine, but the other coal miner who worked 7 years at the same occupation showed less silica than most of the men exposed only in the tunnel. For the sand pulverizers Dr. Louis Gershenfeld furnished reports of analyses which showed from 1.8 to 2.5 per cent of silica in the dry lung tissue. The duration of employment reported for this group seems most untrustworthy.

DISCUSSION

It is indisputable that this group of workmen exposed in three different occupations to high concentrations of silica dust had developed the histological lesions of silicosis by the time of their death. Whether their exposures were actually as short as 8 to 17 months cannot be established with certainty, but their age would preclude any occupation of many years duration. Dr. Smith's analysis of the lung tissues of the tunnel men showed 1.24 to 3.1 per cent of silica in the dry weight of the lungs with histological lesions of silicosis. In the one man with no specific changes his figure was 0.84 per cent. For the sand blasters the corresponding figures varied from 1.81 to 2.45 per cent. These are as high as McCrae's⁶ percentages for ordinary silicosis in South African gold mines. He does not state the duration of exposures in his report but the per cent of silica in 6 dried lungs varied from 1.39 to 4.47 with an average of 2.63. The precise amount of reaction which had developed at the end of the period of employment is unknown as no case came to autopsy at that time. All observations were made from 9 to 20 months later when the men had died of infection. Within this period some change in the lesions would be expected particularly in the presence of infection. The significant feature is that the

gross anatomical changes which had developed at the time of death were not sufficiently extensive or characteristic to be recognized as silicotic in origin.

Strictly speaking, the first question proposed in this investigation has been answered in the affirmative; silicosis can develop under these conditions of exposure but the reaction is of microscopic proportions. Since the men could not have been employed for very long periods because of their ages, and since chemical analysis showed that their lungs contained excessive amounts of silica, it must be assumed that this material accumulated within a comparatively short time.

The second question was whether the silicosis developing under such conditions in any way differed from the usual picture observed in miners, quarrymen, founders, etc. Direct comparison is impossible for lack of pathological material on men dying after short periods of employment in these industries. It is quite possible that the early lesions of the more familiar type of the disease are comparable both in rate of development and character to those described for this series of cases which had been called "acute." In the absence of any other basis of comparison for the rate of development of silicotic nodules, reference is made to animal experiments.⁷ In guinea pigs exposed for from 1 to 2 years to concentrations of approximately 200 million pure crystalline silica particles per cubic foot of air, the number of nodules per unit area was much smaller than that in the human cases under discussion. After 1 year's exposure both were approximately of the same size but the human lesions were completely hyalinized, whereas in the animals this change was only beginning to appear. During the ensuing year the total area of the experimental nodule attained approximately the same size as the central hyaline zone in the nodule of the sand blasters and tunnel

men exposed for similar periods. Whether the difference is a reflection of variation in the reaction to silica in the two species or whether it signifies that the exposures in the human cases were greatly in excess of the 200 million particles per cubic foot of air cannot be ascertained.

The character of the silicotic lesions encountered in these cases differs in three particulars from those usually observed:

1. The individual nodules are small but they are massed in zones of considerable width along the course of the deep and superficial pulmonary lymphatic trunks and they are embedded in wide bands of connective tissue which in many places has itself become hyalinized. In the ordinary case the nodules are much larger, sometimes developing from a single center and sometimes resulting from the fusion of adjacent foci; but they tend to remain discrete and in the absence of concurrent infection they are not matted together in a mass of fibrous tissue.

2. The lymph nodes which drain the lung are ordinarily severely affected before the pulmonary changes have progressed very far, but in about one-third of the cases under discussion there was no evidence of silicosis in this location; and in others the involvement was relatively slight. It is possible that this may have been due to faulty selection of material, but it seems rather unlikely, for in most instances several nodes were sectioned.

3. All of the lungs showed an appreciable generalized thickening of the alveolar walls. Some of this reaction was undoubtedly due to the superimposed infection, but in the acute caseous pneumonias such proliferative changes are absent or not at all prominent.

The objection will immediately be raised that the unusual features of the silicosis which have been described are

only unusual because of the coexistent infection. However, it should be remembered that the caseous pneumonias, at least, were very acute processes, probably non-existent during the period when these men were at work and the primary reactions to the dust were taking place. The group was composed of young adults, negroes in most cases, with probably little or no immunity to tubercle bacillus, so that their infections ran an acute course with a fatal termination in 15 months or less. If they had become infected while their silicosis was in its formative stages they would not have been able to continue so strenuous an employment and many would have died months earlier. It is tempting to speculate that because their microscopic silicotic lesions impaired the efficiency of their pulmonary lymphatics, these non-immune individuals were rendered even more susceptible to the action of the tubercle bacillus. In the non-immune individual with recognizable *advanced* silicosis a primary infection with the tubercle bacillus will sometimes cause death in 3 or 4 months. Whether this is also true of the type of silicosis under discussion remains to be demonstrated.

For these reasons it is believed that the localization of the silicotic nodules in this group of cases was not materially influenced by the terminal tuberculosis. Possibly their rate of development was accelerated by the presence of the infection. If it is granted that the dust concentrations to which the men were exposed were unusually high, this might well be the cause for the peculiarities described. It is known that if dust is inhaled for a long time in concentrations only moderately in excess of the physiological limits, the first manifestations of its presence will be reaction in the lymphatic system, both in the mediastinal lymph nodes and in the lungs. Such is the sequence in ordi-

nary silicosis. On the other hand, if the concentrations are so excessive that lymphatic system is entirely inadequate to eliminate the major portion of the foreign material, reaction would be expected to take place within all portions of the lung. The unusual picture of widespread thickening of the alveolar walls and of broad bands of cellular or hyaline connective tissue studded with nodules along the superficial lymphatics of the pleura and the deep lymphatics in the septa, bronchi, and blood vessels has been interpreted as reaction to excessive quantities of dust.

To what extent the factor of fineness of the dust particles contributed there is little adequate information. The sections, when examined in polarized light, exhibit exceedingly large numbers of very minute particles with comparatively few large ones. Time has been lacking to make a size distribution study of the particles from digested portions of these lungs. Experiments⁸ have demonstrated that in rabbits the rate of the silicotic reaction varies directly with the size of the particles.

Finally, it should be mentioned that the diagnosis of tuberculosis superimposed upon silicosis of this character has often been most difficult. Other pathologists reviewing the same material have in some instances failed to agree. The lesions characteristic of the chronic forms of tuberculosis are often few in number. The necrosis produced by silica in non-tuberculous exudates often simulates caseation which has necessitated the examination of many sections before definite tuberculous lesions could be detected. Tubercle bacilli were only discovered after prolonged search in 50 per cent of the lesions examined. It is unfortunate that guinea pig inoculations could not have been made. If errors have been made it is felt that they occurred in classifying the non-tuberculous pneumonias as such rather than the reverse.

The roentgenographic appearances of the tunnel men have been discussed by H. L. Sampson.⁹ He and the author had opportunity to examine a large number of films from other members of this group, but those of the particular men who died and were autopsied have not yet become available. In the group as a whole roentgenographic evidence of silicosis was very slight or absent; only changes due to infection could be readily recognized.

In view of the fact that microscopic examination revealed so many silicotic lesions, it is perhaps surprising that the X-ray failed to detect them. Analogous situation has been encountered in the roentgenological study of experimental silicosis in rabbits. After 13 months' exposure to rather heavy concentrations of crystalline silica, the X-ray reveals no definite change in the lung of the living animal, and yet if it is killed the lungs show a most extensive nodular silicosis. After 2 years' exposure, however, the amount of disease increases sufficiently to permit the visualization of nodular shadows. The same conditions obtain with respect to miliary tuberculosis in human beings. The lungs may show no evidence of a disseminated process in one examination, but if serial films are taken the time soon comes when tubercles can be visualized throughout the lungs.

SUMMARY

A histological study of 15 cases of so-called "acute" silicosis has been reported. This was based upon examination of the lung tissues of 9 tunnel workers exposed for 9 to 13 months, 3 sand blasters for 12 to 17 months, and 3 sand pulverizers on whom satisfactory histories of exposure were not obtained. Chemical analysis demonstrated that their lungs contained as much silica as those of South African gold miners employed for long periods. Their alleged occupational exposures did

PLATE I

FIGURE 1.—14 months exposure in tunnel; died 13 months later. Silicotic nodules surrounded by cellular connective tissue. Exudate in air spaces.

FIGURE 2.—7 years in coal dust, 13 months in tunnel; died 9 months later. Silicotic nodules larger than those in Figure 3; marked interstitial fibrosis; pneumonic reaction in lower fourth of section, probably tuberculous.

FIGURE 3.—12 months in tunnel; died within a year of acute tuberculous pneumonia. Section through area without obvious tuberculosis. Note clusters of very fine nodules along vessels through the center of the field.

FIGURE 4.—11 months sand blasting; died 22 months later of acute tuberculous pneumonia. Silicotic nodule in right lower corner. Thickened alveolar wall and perivascular cellular fibrosis in right upper field. Necrotic exudate and cholesterol clefts within air spaces.

not exceed 17 months, a contention which is supported by the early age of the group as a whole. These men died of infection 9 to 21 months after ceasing work. In 11 of them the infection was considered to be definitely tuberculous, and in 2 others it was probably so. The other 2 had unresolved pneumonias. All but 1 of them, a tunnel man for 13 months, presented microscopic lesions characteristic of silicosis, but in no case was the disease sufficiently far advanced to be diagnosed on gross examination of the fixed tissues. The character and distribution of the changes did not resemble that usually seen in silicosis among miners and others who have died after prolonged exposures. This silicosis was characterized: (1) by masses of small nodules embedded in broad sheets of fibrous tissue surrounding the pulmonary lymphatics instead of isolated conglomerate nodules along the trunks and in the pulmonary parenchyma; (2) by a generalized fibrous thickening of the alveolar walls which is generally considered to be a late manifestation; and (3) by the absence or only slight involvement of the mediastinal lymph nodes which are usually replaced by fibrosis before extensive changes appear in the lung. These differences were interpreted as due to the inhalation of such excessive amounts of fine dust that little of it could be eliminated by the lymphatics. In most cases the tuberculous complication was so acute that it probably developed after the reaction to the dust was well established, and

thus failed to influence the picture greatly.

The acuteness of the infection was explained by the fact that the majority of the men were young negroes with presumably little immunity to tuberculosis. Although there is histological evidence of silicosis, atypical in character, it seems doubtful whether there is justification for describing the process as "acute." At least this should only be done after serial roentgenograms together with post-mortem examinations have demonstrated the outcome of the allegedly heavy exposures to silica. The difficulty in properly evaluating the element of infection in the tissues suggests the need for caution in the interpretation of roentgenograms.

THE presence of silica in the lungs of an individual at post-mortem suggests the possibility of the disease silicosis during life. The diagnosis of silicosis is based on data secured from three principal sources: the history, particularly the occupational history, the physical examination, and the roentgenological examination of the lungs. Silicosis has been recognized at least until recently as existing in three different stages. The "stages" are given different names by British and American workers but are essentially the same in their clinical manifestations. In the British Dominions these stages are defined by law, but in America this is not true. Not only may silicosis exist in any one of three stages but it may be, and frequently is, complicated by other respiratory diseases, particularly tuberculosis. This complicates the differential diagnosis.

Investigations covering the etiology,¹ clinical manifestations² and roentgenologic aspect³ of silicosis have so recently been made that it is only necessary to refer to the published reports where each of these phases is covered in detail.

The chemical examination of the lungs of persons dying of respiratory diseases offers definite aid in the final

diagnosis of the disease. Unfortunately this means cannot be used until the patient has succumbed, but, nevertheless, the data secured may be of considerable value in confirming previous findings in the adjustment of industrial compensation claims.

When the total number of deaths from respiratory diseases is considered, the number of reported chemical analyses of the lungs of such individuals is very meager. It is, therefore, important that the chemical analyses of any group of lungs, no matter how small, be reported promptly in order that all interested in the general subject of pneumoconiosis may profit by the added information.

Quite recently two papers on the chemical analyses of lungs have appeared, one⁴ in this country and one⁵ in England. Since one appeared in July and the other in August, 1933, it will not be necessary to review the literature on the chemical analyses of lungs at this time (October, 1933). A comprehensive review may be obtained from Dr. McNally's paper.

Silicon is a widely distributed element and exists in nature chiefly in the form of the oxide, SiO_2 , and as silicates of various kinds. Some authorities make a differentiation between silicosis and silicatosis, the one being caused by SiO_2 and the other by silicates. This distinction can only be made with assurance when it is known that the in-

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

haled dust consists principally of silicates and not SiO_2 . Our present methods of chemical analysis of the lungs do not permit of a very accurate separation of free and combined silica. For this reason the silica found in lungs is reported as total SiO_2 which includes both the free and combined forms. Silicosis apparently may be produced by either SiO_2 or silicates when inhaled in the form of dust. Kaolin may be an exception to this statement.⁶ Kaolin when injected into the subcutaneous tissues produces necrotic lesions similar to amorphous silica but in industrial medicine kaolin is not generally recognized as a cause of pneumoconiosis. In dust inhalation experiments on guinea pigs it has been shown by H. M. Carleton⁷ and F. Haynes⁸ that kaolin is at least a potentially dangerous dust. Not only must the dust contain silica or silicates but the dust must be very finely divided in order that the silica may become fixed in the lung. McCrea⁹ reports that approximately 70 per cent of the particles recovered by him from post-mortem lung tissue had a diameter of less than $\frac{1}{8}$ that of a red blood cell.

How silica produces the characteristic changes in the lungs is not clearly understood. The original theory was that because of its hardness, sharpness, and relative insolubility, the silica dust caused direct injury to the lung tissue but this theory has in the main been discarded, principally for two reasons. Recent investigations have shown that the dust particles in order to be absorbed into the lung tissue must be much too small to produce any direct mechanical injury. Furthermore it has been shown that silica is not the totally insoluble substance it was once believed to be.

The modern viewpoint is that the changes brought about in the lung by silica are due to its chemical action. It is only fair to state that it is not known

whether in the lung the silica acts as a protoplasmic poison or whether its action is due solely to its colloidal properties.¹⁰

The material for the present investigation was obtained through the courtesy of Dr. L. R. Harless of Gauley Bridge, W. Va. Previous to the time that the material was made available for us, sections of the lungs had been removed for other purposes so that it was impossible for us to obtain the weight of the entire lungs. The lungs had been preserved for varying periods of time in formalin solution. In no case was a metal-containing preservative used, so that the ash reported represents the true ash content of the lung without any added salts. In some of the specimens it was possible to select portions which on gross examination appeared to be normal. These are designated in our report as "normal," but it does not mean that the portions taken were histologically normal. However, our results show that in the same individual the area that was apparently normal actually did contain less silica than other portions of the same lung. In one or two instances we were able to secure portions of the right and left lung of the same individual.

The material for analysis consisted of 10-15-gram sections taken from various parts of the lung in order to obtain a representative sample. Care was taken to exclude the bronchial lymph nodes, as it was assumed that they would be unusually high in silica. The material thus obtained from each specimen of lung was hashed in a meat chopper. A weighed sample of the hashed lung was dried to constant weight at 100°C . The loss in weight at 100°C . is not recorded in our table as it represents the water content of the lung plus the volatile preservatives and is not a measure of the true value of any lung constituent.

The dried lung substance was then ashed in platinum in a muffle furnace

at low red heat. The weight of the residue was recorded as total ash. The ash was then treated with dilute hydrochloric acid at boiling temperature. The insoluble residue was washed, dried and ignited to constant weight which was recorded as the acid insoluble ash. The acid insoluble ash was then treated with hydrofluoric acid. This converted any silica present into silicon tetrafluoride which volatilized on heating. The loss in weight was recorded as silicon dioxide. It is interesting to note that the weight of the acid insoluble ash and the loss in weight after treatment with hydrofluoric acid were practically identical, showing that the acid insoluble ash was silicon dioxide without the admixture of other substances.

The total ash and the silicon dioxide are reported on the basis of per cent of dry lung substance. In order that our figures may be readily compared with those recorded by other workers we have included in our Table I a column showing the per cent silicon dioxide in the total ash. Some writers record their results as mg. per gm. of dried lung substance. Milligrams per gm. may be readily converted into per cent by dividing the mg. per gm. by 10, which will give gm. per 100 gm. or per cent. However, the majority of analysts in this field have recorded their results in terms of per cent SiO_2 in the dried lung substance or per cent SiO_2 in the total ash.

For the histological diagnosis in each

case we are indebted to Dr. Leroy U. Gardner of Saranac Laboratory, and for the occupational history to Dr. L. R. Harless of Gauley Bridge, W. Va.

The purpose of silica determinations in cases of pneumoconiosis is to secure data from which may be derived some analytical criterion which would materially assist in making a differential diagnosis. The criterion might be an analytical value or a ratio between two analytical values. Both of these ideas have been tried.

In their paper on coal miners' lungs Cummins and Sladden¹¹ calculated a ratio between the combustible material of the lung and the silica content. This ratio was assumed to be an index of the severity of silicosis. In his most recent paper Sladden did not make use of this factor, but classified the intensity of his cases of silicosis on the basis of the per cent of SiO_2 in the dried lung substance. He concluded that when the dried lung substance contained more than 1 per cent SiO_2 the case was probably silicotic, and that when the per cent of SiO_2 in the lungs reached 1.6 there were practically no exceptions to the diagnosis of silicosis.

The literature contains several reports of the analyses of the total ash of lungs. In these reports the silicon dioxide is reported as per cent SiO_2 in the total ash. For a review of these cases reference is made to Dr. McNally's paper. Previous work may be summarized by stating that the older authors believed that silica was not present in the lungs of new-born infants. Three-quarters of a year was the time frequently quoted when silica first appeared. As the number of chemical analyses of lungs of persons of various ages and occupations increases it will probably be shown that the amount of silica in the lungs of normal individuals depends somewhat upon environment as well as upon age. It is obvious that the dust from paved streets or roads will be

different in composition from that of unpaved roads. The composition of dust from unpaved roads will depend upon the nature of the soil in the locality. Normal individuals of the same age having lived all of their lives in different environments will undoubtedly show considerable variation in the silica content of their lungs.

Wells¹² in his *Chemical Pathology* states that lungs of individuals whose occupations do not expose them especially to dust inhalation contain increasing amounts of silicates in direct proportion to age; the silicates then constitute from 3.5 to 10 per cent of the total ash of the lungs.

The 9 cases reported in this paper were men who were engaged in the same project, namely, the construction of a tunnel through rock rich in silica. Their exposure to silica dust depended somewhat upon the nature of their occupation. Our analytical findings with the histological diagnosis and occupational history are recorded in Table I.

Since the purpose of the chemical analysis is to make the diagnosis more definite, some of our data ought to be capable of close correlation with data secured by an entirely independent method of diagnosis. The test will then be a comparison of the chemical findings with the histological diagnosis. If one compares the per cent of ash in the dry lung substance in each case with the histological diagnosis he will note a very good correlation, for the SiO_2 content of the lung increases with the severity of the case. On the other hand, if the severity of the case is to be determined chemically by the per cent SiO_2 in the total ash, the correlation fails. We believe therefore that the per cent SiO_2 in the dry lung substance is a much better criterion of silicosis than is the per cent of SiO_2 in the total ash. Our findings of SiO_2 in the dried lung substance agree essentially with those reported by Sladden.⁵

* High ash due to Kaiserling solution used as preservative.

† SiO₂ calculated as per cent from milligrams per gram as reported.

For the purpose of comparison we have prepared Table II which contains data taken from the publications of other workers in the same field. In the case of Dr. Sladden's article only one section of his analytical report is reproduced. The case numbers in each instance are those of the original authors. In order that the compilation might be truly representative we have included reports from various parts of the world.

SUMMARY

The lungs of 9 workmen engaged in the same tunnel project have been analyzed.

There is a striking correlation between the per cent SiO₂ in the dried lung substance and the severity of silicosis as determined histologically.

CONCLUSION

The per cent SiO₂ in the dried lung substance is a better criterion of the

intensity of silicosis than is the per cent of silica in the total ash.

Some Factors Involved in the Use of Chloramines for the Disinfection of Swimming Pools*

A. H. FLETCHER, F.A.P.H.A., AND E. C. LINK

*Director, Bureau of Sanitation, Department of Health, Memphis, Tenn.; and
Director, Bureau of Laboratories, Department of Health,
Memphis, Tenn.*

IN Memphis, during this summer swimming pool season, the 13 pools that have been operating were studied as a group in the routine health department control program. These pools present a variety of conditions with reference to design, equipment, bathing load, source or chemical quality of the water. They might be grouped into 4 general classes. Four of them are outdoor fill-and-draw pools, while 2 are indoor fill-and-draw pools. Three others are distinctly poorly designed from the standpoint of inlet location or slow rate of recirculation and 3 of the remaining 4 are fairly well designed as to inlet spacing and rate of recirculation but their ultra-violet ray machines have been abandoned and the disinfecting agent must be added by hand. The last of the 13 pools has been built this summer and is designed for an 8-hour "turnover" and with proper inlet and outlet locations to enable the maintenance of a uniform residual in all parts of the pool at all times, using chlorine alone as the disinfecting agent. This is the only pool which has been built within the last 6 years and the only one equipped to disinfect satisfactorily with chlorine alone.

The use of chloramines in swimming pool disinfection has therefore, been of special interest here because of:

1. Its ability to improve the distribution and maintenance of a uniform chlorine residual throughout all parts of the pool and for longer periods of time.
2. The increasing of the permissible upper limit of the chlorine residual. Residuals of up to 1 full p.p.m., if using ammonia with the chlorine. While using chlorine alone the upper limit is 0.5 p.p.m. without causing complaints of odors and smarting of the eyes.¹
3. The definite saving in the cost of disinfection of these pools in past years, using ammonia with chlorine, over those using chlorine alone. For swimming pools having an 8-hour "turnover" period and a satisfactory number and spacing of inlets, the saving shown in the pool studied here would undoubtedly be misleading, as it was necessary in using chlorine alone to maintain excessive residuals in parts or streaks of the pool in order to have a slight, 0.1, or 0.2 p.p.m. of chlorine in other parts.

At the American Public Health Association Meeting in Washington last year, the usual method of collecting samples for bacteriological examination, that is the holding of the samples after collecting for a period of time before testing, was condemned as giving a false feeling of security. Mallmann and Cary² concluded:

Samples of swimming pool water collected during periods of use and tested immediately after collection showed more pollution than duplicate samples handled in the usual manner by storing and testing later. . . .

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

sults of the 42 samples collected, where chlorine was used alone, in sodium thiosulphate treated bottles. The average count was 44 when the residual was 0.1 p.p.m. The average count above this residual never ran more than 136.5 bacteria per c.c. Forty-two samples tested for *B. coli* were all negative. Chart 3 represents the results of 567 samples collected from 11 pools where chlorine and ammonia were used. The average count from the samples collected in the ordinary bottles at 0.1 p.p.m. was 136 and at 0.3 p.p.m. was 4. Five hundred and sixty-seven portions were tested for *B. coli* and there were 6 positives in portions containing less than 0.1 p.p.m. From 11 pools 408 samples were collected in bottles that had been treated with sodium thiosulphate to dechlorinate the sample at the time of collection. The average bacteria count at 0.1 p.p.m. was 220, and the average count at any chlorine residual above 0.1 p.p.m. never ran as

high as 100 bacteria per c.c. as shown by Chart 4. A *B. coli* graph inset in Chart 4 shows the number of positive portions in black and the number of portions tested in the outlined bar.

The work of Schmelkes³ showed that a high free ammonia content slowed up the reaction of chlorine on bacteria. It is interesting to note, however, that the positive *B. coli* samples at 0.6 p.p.m. and 0.5 p.p.m. were collected at times when the pH and free ammonia content were probably normal.

At a residual of 0.6 p.p.m. there were 2 positive *B. coli* portions out of 33 portions tested. The samples from which the 2 tests were made were collected at about 11 A.M. from a fill-and-draw pool 3 days after the pool had been drained, cleaned and filled with fresh water. The bacteria counts on the 2 samples were 10 and 20 for the dechlorinated samples and 2 and 2 for the ordinary samples with the *B. coli* for the ordinary samples negative. No

TABLE I
RESULTS OF TESTS TO DETERMINE POSSIBLE STERILIZING EFFECTS OF
DECHLORINATING PROCESS
Plate Counts

| | Time from addition of chlorine to plating | | | | | | |
|---|---|-------|-------|-------|--------|--------|--------|
| | 0 hr. | 1 hr. | 2 hr. | 6 hr. | 24 hr. | 48 hr. | 1 week |

Nitrite and Ammonia Determinations: Occasional checks were made on nitrite and ammonia content of various pools during the season. In all cases except one, the pools were being operated under normal conditions and no unusual results were obtained.

In the routine swimming pool control programs it was found difficult to control the ratio of ammonia to chlorine that is added by the pool operator, and it was also difficult to control the amount of free ammonia in the pool unless tests for free ammonia were made at times when the Health Department felt that the ammonia content might be increasing to a higher concentration. In the outdoor pools

using chlorine and ammonia, the free ammonia content was kept down so that at no time did the free ammonia content run more than 1.3 p.p.m.

All of the outdoor pools using chlorine and ammonia found it necessary to drain and refill once every 2 weeks because of the increase in temperature of the water. In one of the indoor pools where the pool had been in operation for some 4 weeks, difficulty was encountered in maintaining a residual chlorine content in spite of heavy increases in chlorine dosage. Laboratory tests were made for nitrites, free ammonia, and albuminoid ammonia. The free ammonia content was 8 p.p.m. However, while duplicate

every second night after closing the pool. The copper sulphate was added by dragging 50 lb. in burlap bags around the pool to distribute it evenly. It was necessary to flush or skim the top of the pool each morning after dosing with copper sulphate because of the formation of a greenish oily scum.

OBSERVATIONS AND CONCLUSIONS

1. The decided advantage in the use of chloramines for disinfection of swimming pools having a slow rate of recirculation, poor spacing of inlets, hand application of chlorine, or those operated as fill-and-draw pools, and especially when the pool is out of doors, has prompted its use for another season.

2. The use of chloramines instead of chlorine alone requires certain extra tests and control to guard against its limitations. Some of these are:

- The requirement of higher residuals, that is from 0.7 to 1 p.p.m.
- The control of the ratio of ammonia to chlorine and of the free ammonia content in the water.
- The control of the pH of the water routinely.

d. The collection of all samples in sodium thiosulphate treated bottles. (It is hoped that during the coming season it will be possible to establish a pool side laboratory for checking dechlorinated samples.)

3. The duplicate series of tests run this year on ordinarily collected samples and dechlorinated collected samples showed a lag in the killing power of chloramines over the chlorine on *B. coli*.

4. A moderate excess of sodium thiosulphate when used as an antichlor was found to have no disinfecting effect.

5. Copper sulphate definitely and completely controlled algae or slime growth at any pool where it occurred in Memphis if added every second night after closing at a dosage rate of 5 lb. to each 100,000 gal. of water.

according to Schottmüller. Four were hemolytic.

Puppel (1912) found that out of 18 mastitis streptococci, only 1 was hemolytic on human blood agar.

Jones (1918) described hemolysis in a number of strains which very probably could be termed *S. mastitidis*, but he states: "Mastitis caused by infections with non-hemolytic streptococci is more prevalent than that caused by other classes of microorganisms."

Ayers and Mudge (1922) examined streptococci originating from the udder. Of the 79 strains which were found to be *S. mastitidis*, 64 were of the beta hemolytic type, 15 of the gamma type. The blood medium used was prepared according to Brown and no sugar was added.

Carpenter (1925) found in 150 samples of milk from suspected cases of mastitis, alpha hemolytic streptococci in 79 per cent and beta hemolytic in 6.6 per cent of the cases. Whether the latter were *S. mastitidis* in a strict sense is impossible to say from the data presented.

Minett, Stableforth and Edwards (1929) found more than half of the strains they considered to be *S. mastitidis* bovis to be beta hemolytic and the majority of the remainder to be of the viridans type.

Bergey (1930) gives *S. mastitidis* as hemolytic.

Klimmer and Haupt state (1930): "*S. agalactiae* grows, in our experience predominantly as the alpha type, rarely according to the alpha prime type, comparatively frequently as the gamma type, never as the beta type."

Haupt (1931) never found beta hemolysis in *S. mastitidis*.

Minett, Stableforth and Edwards (1931) stated in answer to Haupt that *S. mastitidis* may be either alpha or beta hemolytic and pointed out that the variation in results between Haupt and themselves was caused by a dif-

ference in composition of the blood medium used. Haupt added 0.05 per cent glucose while they used a sugar-free medium.

Diernhofer (1932) mentions two varieties of *S. mastitidis*, one as an-hemolytic and the other as a beta hemolytic variety.

Seelemann (1932) did not observe hemolysis in true mastitis streptococci. He tested 300 strains using red cells of ox and sheep and 80 on horse blood agar. In some cases a faint clear halo was observed. Steck (1932) examined 24 *S. mastitidis* strains on Brown plates and found that all were of the alpha type. Hadley and Frost (1933) use the name *S. mitis* for the alpha streptococcus responsible for the majority of cases of mastitis. They reserve the term *S. mastitidis* for beta hemolytic types.

Rosell (1933) examined the behavior of 268 strains of typical mastitis streptococci and found 3 only to be beta hemolytic, the remaining being of the alpha or gamma types, using horse and sheep blood in the Brown technic. On cow's blood 10 per cent of the strains were beta hemolytic. No sugar was added to the medium, but horse meat or Liebig's meat extract were recommended.

The disagreement between different authors in regard to the action of *S. mastitidis* toward blood media may be due to several reasons: (1) The name *S. mastitidis*, may be taken in too broad a sense including practically any streptococcus that may be isolated from the udder. (2) Differences in technic, composition of the medium, kind of blood, observation of surface colonies being the most important. (3) Difference in interpretation. Alpha prime colonies are, no doubt, frequently regarded as beta colonies.

The object of this discussion is to present data regarding the action on blood of authentic strains of *S. masti-*

that it approaches the beta type. This circumstance explains in a satisfactory way the discord in the conception of Minett, Stableforth and Edwards (1931) on the one hand, and Haupt on the other, as the former investigators used a sugar-free blood medium and the latter one which contains 0.05 per cent glucose. Some variance in the appearance is found when different kinds of blood were used, but in the case of the strains here concerned the variation was not great and only 2 (No. 4 and No. 78) showed a sufficient difference to cause a placing into different types, viz., alpha and alpha prime.

Agreement between the hemolysis on the plates and in the liquid medium was never perfect.

SUMMARY

Of 91 authentic strains of *S. mastitidis* being carried in various laboratories as typical streptococci associated with mastitis, 50 were of the alpha and 41 of the alpha prime hemolytic types.

The streptococcus commonly associated with chronic or subclinical mastitis always produces the alpha or alpha prime type of hemolysis on blood agar bordering on a slight beta hemolysis. Strong beta hemolytic strains were not found among the cultures. Two strains of streptococci from mastitis were beta hemolytic, but they were found by cultural studies to be different from the type generally found associated with mastitis.

A careful study of the authentic mastitis streptococci isolated from chronic cases reported to be beta hemolytic were found to be of the alpha prime type. This distinction is apparent when deep colonies are examined by a stereoscopic binocular microscope.

Blood from sheep, ox, and horse were used with similar results. The type of blood did not appear to affect the type of hemolysis produced on blood plates.

Outbreak of Erythema Infectiosum in Elmsford, N. Y.

PHYLLIS SCHUYLER KERR, M.D.,

*Associate Attending, Skin Clinic, New York Post-Graduate Hospital,
Columbia University, New York, N. Y.*

AND EDWARD H. MARSH, M.D., DR.P.H., F.A.P.H.A.

*Deputy Commissioner, Westchester County Department of Health,
White Plains, N. Y.*

IN March, 1933, the Westchester County Health Department was asked to assist in the diagnosis of a case of erythematous eruption in a young child living in Elmsford, a village of 3,000 population. At the time a tentative diagnosis of erythema multiforme was made by one of us (E. H. M.). A few days later a similar case was seen by another member of the department staff and the same diagnosis made. Within the next few weeks the local public health nurse and school nurse discovered what seemed to be a rather extensive outbreak of the disease, confined entirely to children below the age of adolescence. With the knowledge of the occurrence of so many cases all confined to one age group, the diagnosis of erythema multiforme seemed to be out of the question. The nurses were asked to gather together as many of the cases, both new and old, as could be found for reexamination by both of us.

On April 28 about 20 cases were brought together, the youngest 3 years of age, the oldest 13. All had had the eruptive disease during the previous 4 weeks and all but one or two showed signs of the eruption. The eruption consisted of a (subjectively) asymptomatic reticulated erythema found in nearly all cases on the arms and legs; in a few the upper trunk and neck were also in-

involved, while in one or two there was distinct flushing of the cheeks. In one of the cases seen earlier there had been in addition to the distribution described, a distinct butterfly patch across the nose, extending to the malar eminences. A very few of the children had signs of chronic tonsillar infection; some of the more recent cases showed redness of the fauces and tongue; while in one fresh case there were distinct well marked patches on the tonsillar pillars and buccal mucosa. Such conditions were exceptional, however, oral manifestations not being noted in most cases; nor was there any history of sore throat in the majority.

As a result of this reexamination it was determined that the outbreak was one of erythema infectiosum (Ringelröteln), (Fifth Disease). The first clinical report of this malady was in 1925, by Herrick,¹ who recorded in a most complete article 74 cases. He stated that the disease was accurately described in the German literature in 1886, was recognized as a distinct entity in 1896, and given the name "Erythema Infectiosum" in 1899. There have been reported epidemics of the disease in Germany, Italy, France, Netherlands, Manchuria, and in the United States in Utah, St. Louis, Cleveland, Albany, Hamburgh, N. Y., and Branford, Conn.

CHART I

25 CASES OF ERYTHEMA INFECTIONOSUM, RINGFORD, N. Y. 1933

Distribution by Week of Onset

The description of the disease recorded by Smith² conforms closely to the eruptions observed by us. With no prodromal symptoms the eruption appears on the face, chiefly the cheeks, in the form of a bluish-red flush, rather sharply demarcated and on close inspection is seen to be composed of macular elements. Sometimes a distinct butterfly patch is observed. At first glance the eruption resembles erysipelas although it is readily seen that there is no induration nor co-lateral edema. There may be a burning sensation with possible itching³ (absent in all of our cases). On the second day the eruption appears on the outer surfaces of the arms and legs, the buttocks, and less often on the trunk. The rash spreads peripherally and as it fades in the central portions, gyrate map-like mottling remains which often persists for as long as 3 weeks, following the initial eruption. The duration varies from a few days to several weeks, sometimes fading almost completely only to return, fade and return many times. A brisk rubbing often makes the rash

more noticeable. Shaw⁴ describes an evanescent vermilion coloring of the tip and edges of the tongue which may appear and disappear during the course of an examination.

There is no lymphadenitis and seldom any fever, at times there is slight temporary gastrointestinal disturbance and occasionally redness of the throat has been observed. The leucocytes may at first be diminished and then slightly increased, the eosinophil count ranging from 5 to 10 per cent.

The disease is of unknown etiology. It is unquestionably infectious and communicable but the symptoms are of so little moment that isolation is not warranted and no treatment is required. It occurs mainly among children of from 4 to 12 years of age and apparently is more common in the spring and summer months. The incubation period seems to be from 4 to 14 days.

Erythema infectiosum must be differentiated from erysipelas, German measles, scarlet fever, measles and erythema multiforme.⁵

This report is of interest chiefly in

adding another place to the list of communities in which erythema infectiosum has been identified and in recording such limited epidemiological data as were discovered, although much of this is of a negative character.

The present series of cases totalled 25 and the likelihood of there having been any considerable number of unobserved cases is slight. The local physicians were on the alert for the disease and the public health nurse and school nurse of the village were in touch with almost every family in the community. Indeed, it was only through their efforts that this group of cases was assembled. The age distribution was from 3 to 13 years, most of the group being under 10 and nearly one-third under 6 years of age. The cases were distributed almost evenly as to sex.

The outbreak extended over a period of 11 weeks, the first case having had its onset March 10, the last 2 during the third week of May. The week during which the largest number of cases occurred was that of April 11-17, the sixth week of the outbreak. The accompanying chart shows the cases by week of onset. It is apparent that the evolution of the outbreak was gradual and that its subsidence was equally slow, showing that there was probably no common source of infection and that in all probability the disease spreads by contact.

There were 4 instances of multiple cases in one family. In the first family 1 child's onset was March 18, the other April 3, a 16-day interval; in the second the onset in 1 child was April 16, in the other 4 days later; in the third there was a 4-day interval between cases; in the fourth family 2 of the cases occurred simultaneously on April 13, the third case 8 days later. In addition to these 1 child whose onset was March 18 lived next door to and played with the child whose onset was March 10. These intervals correspond closely to

the belief previously noted that the incubation period is from 4 to 14 days.

In the two schools in the village there was practically no difference in incidence among the pupils. Most of the children came from clean houses and from families of moderate means. The cases were scattered irregularly throughout the village, there being no well defined geographic concentration.

As to possible etiology, no logical cause was discovered. This is consistent with the intensive investigation and careful clinical reports by Lawton and Smith,⁶ in 1931. The water supply of Elmsford is of good sanitary quality and is secured from the Catskill aqueduct, part of the New York City supply. All of the milk sold in the village is produced and distributed under the supervision of the Westchester County Department of Health and is obtained chiefly from two of the largest distributors covering New York City and the surrounding suburban territory. Furthermore the distribution of cases was such that no one milk supply could possibly be implicated. Most of the usual foods supplied to the residents of the village, were secured from one or another of several chain stores operating in the community. Evidence suggesting any one store or any one food as the source of the outbreak was lacking. About 25 per cent of the village is sewered, the residents of other property relying on cesspools or septic tanks for sewage disposal; there are few, if any privies. There is no evidence of correlation between the cases and the method of sewage disposal.

Both whooping cough and chicken pox were prevalent in the community during the time of this outbreak, but apparently the cases of erythema infectiosum were not more common among the children who had either of these diseases or had been exposed to them. It was suggested that immunization against diphtheria by toxoid, or the use

of pertussis vaccine in the treatment and prevention of whooping cough might have been causative factors, but only 2 of the cases in our series had had any such treatment during the few months immediately preceding the outbreak.

SUMMARY

During the spring of 1933, an outbreak of erythema infectiosum occurred in the Village of Elmsford, Westchester County, N. Y. There were 25 cases ranging in age from 3 to 13 years. The outbreak extended over a period of 11 weeks and apparently was spread by contact infection. Evidence pointing to any definite etiology is negative. The disease is characterized by a typi-

cal eruption accompanied by few, if any, other symptoms. From a study of the literature and this present outbreak it would seem to be logical to believe that outbreaks of this disease may be fairly common but unrecognized.

Pulmonary Asbestosis*

J. DONNELLY, M.D.

Mecklenburg Sanatorium, Huntersville, N. C.

THE manufacturing of asbestos products in the last few years has assumed a somewhat greater importance in the industrial world. Although the total number of workers in asbestos mills is probably far smaller than in many other lines of trade, their health is of paramount importance. The conditions surrounding the greater proportion of the employees constitute a distinct and serious industrial hazard, and often sufficient devices for protection have not been provided. It is doubtful if any single employee in certain departments of these mills can possibly escape some damage to his respiratory system because of the unavoidable inhalation of asbestos dust. Naturally, the longer the service of an employee, the more certain is more or less extensive pulmonary damage.

Asbestos is composed principally of magnesium silicate in crystalline hydrated form, always found with other minerals, particularly iron and magnetite, and usually contains about 2.6 per cent free silica. The rock is blasted in open quarries, being afterward crushed and pulverized, although often the pulverizing is done at the mill where the finished product is produced. At the mill the fibers are mixed with other fibers, usually cotton, then carded and spun by processes very similar to those employed in the production of cotton goods. In all of these processes a considerable quantity of asbestos dust is

produced. Cooke states that the asbestos fiber microscopically consists of two different elements, (1) the glistening material which constitutes the bulk, and (2) black opaque angular particles. The dust contains these particles and minute granules. Analysis of samples showed that the dust with the greater quantity of these black particles contained the largest amount of iron. As the dust contained 18.4 per cent of iron and the finished product only 0.1 per cent, Cooke concluded that the black brittle parts of the fiber are the cause of the dust, and the danger to the health of the workers. Since the asbestosis bodies found in the sputum of disabled workers have been found to have cores which appear to be asbestos fibers around which has been deposited some kind of material from the living tissues, the iron-containing particles cannot be the sole cause of the condition. In fact, Gloyne, in 1929, showed that the core of the "asbestosis body" is an asbestos fiber.

The "dusty trades" for a long time have been considered inimical to the health of employees. In spite of this it has only been within the last 10 years that "pulmonary asbestosis," a disability resulting from working in one of the dustiest of trades, has been to any appreciable extent recognized. The first recorded case of "asbestosis" was reported by Dr. H. M. Murray at Charing Cross Hospital in 1900, and his diagnosis was supported by necropsy findings. The man was the only survivor of 10 who had worked in the carding room of an asbestos mill 10 years

* Read before the Industrial Hygiene Section of the American Public Health Association, at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

previously. From 1900 to 1924 not a single case report of the condition appears in the literature. In 1924 Cooke¹ published an autopsy report on a case who had worked in an asbestos plant for 20 years. Cooke thought this was the first case to be reported. After having learned of Murray's case, in 1927, he wrote a second article describing in more detail the pathological findings in his case.

McDonald,² in 1927, published an article on the microscopic appearance of lung tissue in asbestosis, his material having been obtained from Cooke's case. In 1928, Simson³ reported the findings in lung sections from 4 asbestos workers, 2 of whom died from pulmonary tuberculosis and 2 from pneumonia. The author discussed at length the "golden-yellow bodies" now known to be pathognomonic of asbestosis. Page and Wood,^{4,5} in 1929 and 1930 recorded 2 autopsies. Lynch and Smith⁶ reported the complete autopsy findings in a case which apparently died of pulmonary asbestosis, and had previously reported 2 autopsies on asbestos workers, 1 of whom died of gunshot wounds and the other of lobar pneumonia. They had been able to find only 172 cases of pulmonary asbestosis in the literature up to 1931, and post-mortems had been made in only 18 of these, 9 of which were complicated by other diseases and 1 a traumatic death. Since 4 reports were not completed, there remained at that time (1931) only 4 records of uncomplicated pulmonary asbestosis.

Since 1931 the reports of cases diagnosed as pulmonary asbestosis have been more or less fragmentary, being, in the main, adaptations of pathological facts from the previous post-mortems to the individual diagnosis in each case. Special stress has continuously been laid on the finding of "asbestosis bodies" in the sputum in order that the diagnosis may in no way be doubtful.

The principal pathological findings are pleurisy, extensive fibrosis in the parenchyma of the lung, usually over the mid-portions and bases, and the contraction of the lungs due to this fibrosis. The finding of asbestos fibers and asbestosis bodies is a usual feature, although they cannot always be demonstrated in the sputum of the living case. The fibrotic changes in the lung are the result of the low-grade inflammatory reaction caused by the asbestos fibers, which are supposed to act both as a mechanical and a chemical irritant. The mechanical irritation is evidenced by the large amount of granular dust and the larger angular particles found in microscopic sections. The chemical action is probably due to the presence of silicic acid, or silica, in the mineral, which is usually estimated at 2.6 per cent. Asbestos is very slightly soluble, and the formation of asbestosis bodies and pulmonary fibrosis are supposed to be due to this irritant action.

Gardner and Cummings⁷ studied the production of experimental asbestosis in animals. Guinea pigs, rats, and rabbits were exposed to heavy concentrations of asbestos dust for varying periods, some as long as 2 years. In guinea pigs killed after 847 days of exposure, as well as some with a much shorter term, the authors found that the dust did not reach further than the bronchioles, whereas other dusts are usually deposited in the terminal air sacs and alveoli. This difference in localization they decided was due to the fact that asbestos dust is invariably principally elongated fibers. Along the bronchioles more or less mild inflammatory reaction was found, and fibrous tissue was formed after 1 to 2 years' exposure. After 782 and 840 days' exposure the pleura was involved with sub-pleural grayish white nodules 1 mm. in diameter, pleurisy being frequent in animals which had been long exposed. After 1 year's exposure the X-ray films

of guinea pigs showed definite pathological changes of a fibrotic character. Asbestosis bodies were found to be abundant in the regions around the bronchioles, but less so elsewhere. The condition appeared to follow the course of a slowly spreading fibrosis, even when not complicated by a tuberculous infection.

The so-called "asbestosis bodies," which are usually considered pathognomonic of asbestosis, are never found in crude asbestos. They are invariably found in lung sections, from expressed lung juice, and very frequently in the sputum of patients. They are undoubtedly formed by the deposition of certain material around the inhaled asbestos fibers. Fissures form in this material and the body separates into segments. More than 40 different varieties have been found, varying from golden-yellow to a mahogany-brown. They do not stain with the ordinary tissue stains, but frequently give the Prussian-blue reaction for iron, probably because of iron derived from the tissues. The bodies may be found in the centrifuged material from sputum which has been digested with 10 per cent sodium hydrate, and they vary considerably in length and breadth as they do in form. They are often found with one or both ends encased in phagocytic cells, and frequently phagocytes are seen containing fragments. It has been demonstrated by dissolving the bodies in concentrated sulphuric acid that the middle is composed of actual asbestos fibers, which are very slightly soluble.

The symptoms and physical signs of pulmonary asbestosis simulate to a considerable degree those of fibroid tuberculosis, or atrophic pulmonary emphysema, and because of this many of these cases have previously been diagnosed pulmonary tuberculosis. A few of them are complicated by a tuberculous condition, but not by any means as fre-

quently as in silicosis. No conclusive proof that asbestosis renders an individual more susceptible to an active tuberculous infection has been given. In my series of cases I have been unable to deduce any proof that the condition has any tendency even to cause an exacerbation of activity in an old tuberculous process. The symptoms of the condition, with the exception of dyspnea, are rarely extreme. The skin frequently has an unhealthy somewhat sallow hue, and occasionally, especially in cases with long exposure to inhalation of the dust, one notices slight clubbing of the fingers, although this is far from constant. There is loss of appetite and often slowly progressive loss of weight, with accompanying lassitude. These patients almost invariably complain of chest pains, due to the tendency of the condition to involve the pleura. The cough is variable, often not excessive, and the sputum is usually scanty, being of a tenacious mucoid character. There may be blood-streaked sputum, or definite small hemorrhages, but this occurrence is fortunately not frequent. The temperature as a rule is not elevated to any appreciable extent. The most prominent and distressing symptom is dyspnea, which, very frequently, is extreme. In fact, this symptom usually first calls to the attention of the patient his need of medical attention, and renders him incapable of earning a livelihood. Sometimes, especially after an exposure over a period of years, the dyspnea grows progressively worse even though there has been a cessation of exposure for a considerable period of time. Occasionally this symptom is so distressing that it precludes any form of muscular exertion.

The physical signs of pulmonary asbestosis are principally those of pulmonary fibrosis, usually considerably more extensive over the lower two-thirds of the lungs. There is frequently some muscular atrophy over the chest,

and expansion is very much restricted. The percussion note over the whole chest is higher-pitched than normal except in the apices where the note is frequently resonant, probably because of compensatory emphysema. Although invariably bilateral, the impairment of resonance is more marked on the right side. The physical signs on auscultation are diminished to feeble breath sounds, prolonged and roughened expiration, and either dry crackles, moist râles, or both, usually over the lower half or two-thirds of the lungs. On the whole, the physical signs are quite similar to those found in uncomplicated silicosis, fibroid tuberculosis, or atrophic pulmonary emphysema. There are no definite physical signs distinctive of the condition. Signs are supposed to develop in less than 10 years' exposure, but they are frequently discovered within 2 years. The shortest time in my series of cases, from exposure to the development of symptoms and physical signs, was 18 months. The continuously progressive cases often develop extensive bronchiectasis, or engorgement of the right heart with progressive heart failure as a terminal result. Bronchopneumonia is frequently a serious complication.

The X-ray films show a somewhat distinctive picture. According to Mewether,⁸ if films of asbestosis subjects be compared with those of victims of silicosis, the amount of disease in the former will be underestimated, because of inherent differences in the underlying pathology. The nodular distribution of the fibrosis in patients with silicosis is not often found in asbestosis. In the earlier stages of asbestosis the films present what has been frequently called a ground glass appearance. Later there is more definite mottling, but the lesions are never as dense as those of silicosis; consequently, it is difficult to divide the progress of the condition into stages. Stereoscopic

films show that the ground glass appearance is caused by the development of a very fine fibrosis, and this is almost invariably seen to be much more extensive in the basal portions of the lungs.

Evidence of pleuritic involvement is often indicated by obliteration of the costo-phrenic angles, and flattening or peaking of the diaphragm. Often the diaphragm is indistinct in outline. The films sometimes show some thickening of the parietal pleura. The outline of the heart shadow is often "shaggy," the degree depending on the length of time of exposure to the dust. Occasionally calcareous deposits are seen not only around the hilum of the lung, but scattered in the parenchyma as well. On the whole, in well advanced cases of asbestosis, X-ray films do not show the amount of pathological change that one would expect from the clinical signs and symptoms. Even the most severe cases do not show such definite X-ray evidence as is seen in silicosis, although the area of involvement is usually somewhat extensive.

During the past 3 or 4 years I have collected 15 cases of asbestos workers who have been referred to our chest clinic because of symptoms referable to the respiratory system. With one exception, these have had a diagnosis of pulmonary tuberculosis. Invariably their principal and most distressing symptom has been dyspnea, in combination with slight or more severe cough, lassitude and progressive although gradual loss of weight.

Having had occasion some years ago to familiarize myself with the conditions in asbestos factories, I have since been intensely interested in determining the extent of the industrial hazard in this type of work. For that reason I have attempted to obtain X-ray films of the lungs of all asbestos workers who have been referred to the clinic because of respiratory symptoms. Of the films taken, only 3 have failed to exhibit

some definite evidence of the condition called pulmonary asbestosis. Although this series is comparatively small, it seems reasonable to conclude that this condition is far more frequent among asbestos workers than is usually supposed, in spite of the increased attention paid to the condition in the past 4 or 5 years.

Case histories with the X-ray films of 3 patients may be of interest. All of the cases are still living, although totally disabled. I have not been able to demonstrate asbestosis bodies in the sputum, which should not be absolutely necessary for a diagnosis when the X-ray film shows unmistakable pathology, and the physical signs indicate more or less widespread involvement.

Case I—D.S.W., white male, age 64 years. Came under observation Jan. 8, 1929. His complaint for 6 months had been cough and dyspnea, combined with anorexia and loss of weight. He had worked for 18 months in the card room of an asbestos plant with no protective devices. He had considerable cough, although the amount of sputum was not large and was negative for tubercle bacilli. There was a history of only a very slight rise of temperature at any time. There was slight hoarseness at times. The expansion was noticeably deficient over the whole chest and the resonance was slightly impaired over the lower lobes. The breath sounds were prolonged anteriorly over the mid-portion of the lungs, and, posteriorly, from the middle of the scapula to the base. Over the latter region there were many dry crackles and moist râles.

The X-ray films showed considerable thickening around the hilum. The heart outline was shaggy, and both costo-phrenic angles were obliterated. The diaphragm was irregular and indefinite in outline. The lower two-thirds of the lungs were hazy and infiltrated with fine fibrous lines, and over the left base there was a considerable area of fairly heavy mottling.

This patient was put on complete rest for 5 months, during which he gained 30 pounds. At this time (4 years after becoming incapacitated) he is working as night orderly in a tuberculosis sanatorium, but his cough and dyspnea show no improvement. X-ray films show no clearing of the condition. He suffers at rather frequent intervals with

chest pains, and about 3 months ago had an attack of fibrinous pleurisy with a rise of temperature to 102°.

Case II—C.A.B., white male, age 73 years. Patient appeared at clinic June 13, 1931, with cough and distressing dyspnea; had lost a few pounds, and had the appearance of a very ill man. He had worked practically continuously in the card-room of an asbestos plant for 8 years, but had been compelled to quit work about 6 weeks before on account of extreme weakness and shortness of breath.

The paroxysms of dyspnea, even on the slightest exertion, were severe. Talking apparently required considerable effort. Expansion was much deficient over the whole chest, the intercostal spaces being drawn inward on inspiration. Resonance was impaired over the lower two-thirds of both lungs, and the expiration was prolonged and roughened from the apex to base on both sides. There were dry and moist râles anteriorly from the 3rd ribs downward and posteriorly on both sides from apex to base. The breath sounds were considerably diminished over both lower lobes posteriorly.

X-ray films present a fairly typical picture of asbestosis. The right costo-phrenic angle is obliterated and the right leaf of the diaphragm is irregular in outline and peaked by adhesions. The left costo-phrenic angle is partially obliterated. The lung fields present the ground glass appearance. Around both hilum are numerous apparently heavily calcified areas, and there are several such small areas scattered through the parenchyma of the lung. Stereoscopic examination of the films shows a fibrotic involvement of both lungs which is much more extensive over the lower lobes. In both bases there are fairly extensive areas of heavy mottling.

This patient, 2 years after the condition was first recognized, is still living, but his symptoms have in no way improved, and he remains totally incapacitated. The eventual fatal result by progressive cardiac failure appears to be inevitable.

Case III—R.G.J., white male, age 31 years, was admitted into the sanatorium on April 21, 1930, with a diagnosis of pulmonary tuberculosis. His complaints were lassitude, loss of weight, and cough, which symptoms had been gradually growing worse for 1 year. He had lost about 30 pounds, and, on account of weakness and shortness of breath, had been compelled to quit his work about 4 weeks before. His daily temperature, he stated, had not exceeded 100° F. He had worked in the card-room of an asbestos mill, in which there were some protective devices, for about 4 years.

FIGURE I. CASE 1 Pulmonary Asbestosis
Roentgenogram, June 13, 1931

FIGURE II. CASE 2 Pulmonary Asbestosis
Roentgenogram, June 13, 1931

FIGURE III. CASE 3(A) Pulmonary Asbestosis
Roentgenogram, April 23, 1930

FIGURE IV. CASE 3 Pulmonary Asbestosis
Roentgenogram, September 2, 1931

The man was thin (weight, 127 lbs.) and his skin sallow. The clavicles were prominent and there was poor expansion over the whole chest. The resonance was impaired over both lower lobes; expiration was prolonged and roughened over the mid-portion of the lungs anteriorly, and from the 3rd to the 9th dorsal spines posteriorly. There were moist râles on the left side anteriorly from the 2nd to the 4th ribs, and posteriorly on both sides from the 4th to the 9th dorsal spines. The breath sounds were much diminished over the bases. The sputum was negative for tubercle bacilli. No asbestosis bodies were found in the sputum.

X-ray films taken March 23, 1930, show both costo-phrenic angles partially obliterated. The heart outline is somewhat shaggy, and

there is much thickening around the hili. Throughout both lung fields is a snow-flake mottled density, which is much heavier on the right from the 5th to the 8th ribs anteriorly.

This patient was kept in the sanatorium for about 13 months, during which time his appetite and digestion improved considerably and he gained 38 pounds. His temperature, never over 100° F., became normal after about 6 weeks' rest and remained so until his discharge. His cough improved considerably, but at discharge he was still troubled with dyspnea. X-ray films of his lungs taken Sept. 2, 1931, 15 months after the first films, show an increase in the characteristic fine fibrosis. This is particularly noticeable over the right base over the area which showed in the first

films as a heavier shadow. The heart is more shaggy in outline, the diaphragm is flattened on both sides, and there is apparently increased retraction of the lower ribs. Although the patient appeared to have remained in good physical condition, the X-ray films indicate some increase in pathology. This man is still living, but remains incapable of continuing remunerative employment for any length of time.

These cases are typical of the condition found in each patient of the series, and, from the symptoms and X-ray findings, it seems justifiable to assume that the exposure to asbestos dust is the cause of their total and permanent disability. That exposure to the inhalation of this dust for even a comparatively short time is a definite and serious industrial hazard, has been too frequently indicated to be open to doubt. The fact that the condition when once acquired is permanent and more or less rapidly progressive is most important from a public health viewpoint. It also seems to be the consensus of opinion, not only among writers on the subject, but also among the asbestos workers, that the protective devices now in use in many plants are most inadequate.

The compensation laws in North Carolina do not list this disability as entitling the worker to proper remuneration, and I presume that legal status obtains in other states. In England, in 1931, the Asbestos Industry Regulations were made legally mandatory. These Regulations require the substitution of wet methods for dry, the enclosure of dust producing machines, the substitution of enclosed mechanical methods for hand conveyance and for dusty hand work generally, and the installing of exhaust drafts at dust producing points. In the same year it was also made obligatory for workmen in asbestos plants to appear for periodic medical examinations as a means of preventing or arresting the development of asbestosis.

If any similar regulations have been adopted in this country I am not familiar with them. Asbestos factories produce various necessary and valuable articles of commerce, and are, consequently, important parts of our industrial system. For that reason, if for no other, the workers should be provided with every facility for the protection of their health, so that they may earn a livelihood for themselves and families, for at least an average period of time, at the occupation in which they are most skilled. Unfortunately, every worker handicapped by pulmonary asbestosis becomes almost invariably physically incapable of engaging in *any* occupation, and many of them become an added expense to the welfare agencies of the community. Although the number of asbestos workers is much less than that in many other industries, their occupation is extremely hazardous, and they are amply justified in expecting whatever protection it is possible to give them. Furthermore, the fact that efficient protective devices in this industry, in spite of the added expense, will effect a substantial financial saving, is becoming more apparent. The workers themselves are becoming informed of the danger to health, and many civil suits for damages against factory owners are the result.

Has Diabetes Become More Prevalent?*

CHARLES BOLDUAN, M.D., F.A.P.H.A.

*Director, Bureau of Health Education, Department of Health,
New York, N. Y.*

PRACTICALLY all the textbooks on the practice of medicine published 60 or 70 years ago speak of diabetes as a rare disease, and more common among men than women. At present every physician encounters cases of diabetes, and the disease is known to be very common. Mortality statistics generally show a marked increase in the registered mortality rate of diabetes during the past 50 or 60 years, an increase which has been especially great among women. Do these facts indicate that diabetes has really become increasingly prevalent? This is not an academic question. If the disease has really become more prevalent we should seek for the causative factors with a view to combating any which are preventable.

Prior to the middle of the last century the presence of sugar in the urine was detected (a) by the sweet, honey-like taste of the urine, and (b) by the formation of sugar crystals when a drop of urine was allowed to evaporate on a glass slide. No wonder that one of the older authors speaks of the repugnance which physicians had for testing the urine by taste. Trommer's qualitative chemical test for sugar was introduced in 1842, and Fehling's quantitative test in 1848. A careful study of the medical histories of New York Hospital indicates that even 30 to 40 years after these simple tests were available, no routine tests for

sugar were made of the urine of medical patients. Not until some time between 1880 and 1890 was this present-day routine procedure introduced in this leading hospital. Undoubtedly the general practitioner lagged far behind. The conclusion is justified that diabetes was not recognized because it was not suspected, and because routine tests of the urine for sugar were not made. The textbook teaching that diabetes was a rare disease fostered this neglect to look for diabetes.

MORE COMMON AMONG MALES?

A considerable proportion of cases of diabetes has been discovered accidentally as the result of urine tests made in connection with life insurance. Data collected by the writer show that during the past 30 years the proportion of women examined for life insurance has trebled. Moreover the total number of policy holders, both male and female, has increased enormously during this period. The entrance of a large army of women into industry and the extension of industrial medical services have also increased the proportion of women whose urine has been tested for sugar. There is no convincing evidence that 40 or 50 years ago diabetes was really less prevalent among women than men. It is more reasonable to believe it was merely detected less frequently.

SIGNIFICANCE OF THE INCREASING REGISTERED MORTALITY

Because of the preference given to

diabetes in the classification of deaths due to joint causes, the increasing mention of diabetes on the death certificates (due, in turn, to an increasing recognition of the disease) has resulted in a rapidly mounting death rate charged to diabetes. Much of this increase is fictitious, for many of the deaths represent merely the death of a diabetic individual from some other cause. With a further increased recognition of cases of diabetes, the registered mortality may be expected to rise still higher so long as this statistical practice continues, and this, in spite of the fact that through better treatment, deaths truly chargeable to diabetes decline in frequency. Mortality statistics of diabetes must therefore be used with the greatest caution and with an appreciation of their marked limitations.

OUR AGING POPULATION

Since diabetes develops most commonly after middle life, the aging of our population (because of the declining birth rate and the cessation of immigration) has a marked influence in increasing the prevalence of diabetes. In New York City the proportion of persons over 45 years of age in the population has increased approximately one-third during the past 30 years.

In New York City another factor has led to an increased prevalence of diabetes; namely, the relative increase in the Jewish population. In 1900 this group was about 17 per cent of the city's population; in 1930 it was approximately 30 per cent. Studies by Weiner, of the Department of Health, indicate that diabetes is considerably more prevalent among Jews than non-Jews.

PREVALENCE OF DIABETES

Diabetes is much more prevalent than is generally believed, but inasmuch as the disease is not reportable, no figures are thus far available. The writer has

undertaken to determine the incidence of diabetes in New York City by means of sampling, using for this purpose the results of urine examinations of patients admitted to the state hospitals for the insane, from the New York Metropolitan area. The compilation must, of course, be made by age and sex. Life insurance statistics as well as incidence studies from general hospitals are open to the objection that the individuals represent selected groups. A large body of statistical material from state hospitals for the insane seems best adapted to throw light on the prevalence of diabetes, and it is therefore recommended that health officers throughout the country collect such information from these institutions.

The writer believes that, aside from the increased prevalence of diabetes due to the aging of the population, an increase which must be accepted as real, (and in New York City also the increase due to the larger proportion of Jews in the population), diabetes was probably about as prevalent 50 years ago as it is now. He feels that the increase, during the past 30 or 40 years, in the diabetes mortality in the various age groups finds an adequate explanation in the more frequent recognition of the disease in recent years. In this connection one should remember the attention drawn to diabetes by the work of Allen, and especially by the discovery of insulin by Banting and Best in 1921.

OVEREATING OF SUGAR AND OTHER FACTORS

If it be accepted that, apart from the effect produced by the aging of the population, diabetes really has not become more prevalent during the past 50 years, it will be clear that we should not charge the rising diabetes mortality rate to the increased per capita consumption of sugar, or to some other alteration in our diet, or to some marked change in the relation between

our expenditure of physical energy and our food intake. All of these alleged factors have their advocates. Certainly it would be difficult to explain why these factors should affect the mortality rate of females exclusively, for when due allowance is made for the age factor, the increase is limited to diabetes deaths in females.

One of the chief problems facing

health administrators is the difficulty of dealing with the diseases of later life. Because of the amenability of diabetes to treatment and the experience of physicians in prolonging the lives of their diabetic patients, the wider recognition and the proper treatment of cases of diabetes will help to increase the expectancy of life in the higher age groups.

School Medical Inspection in Madrid

THE introduction of medical inspection in the public elementary schools of Madrid as a beginning of a nation-wide system was ordered in a decree of June 5, 1933.

The decree prescribes the appointment, following a competitive examination, of 34 physicians and 23 nurses; some of these physicians and nurses will make the physical examinations of the children in the schools; the rest will constitute the staff of a dispensary for school children which will be established in Madrid.

All the physicians in the school medical inspection service will constitute a

technical board. This board is to make studies and prepare reports at the order of the Minister of Public Education and to suggest necessary measures.

The work will be under the supervision of a chief medical inspector appointed by the Minister of Public Education, who will also be the chairman of the technical board. Graduate courses will be established for the physicians who are to serve as school medical inspectors when such inspection is introduced in the other cities of Spain. Detailed regulations for the functioning of this system will be issued at a later date.—*Gaceta de Madrid*, June 7, 1933.

Significance of Copper and Iron in Blood Restoration*

C. A. ELVEHJEM, PH.D.

University of Wisconsin, Madison, Wis.

DURING the past few years much attention has been given to the iron and copper content of foods and to iron and copper preparations used for blood restoration. It is logical for us to ask, what is the practical significance of these studies? and how much consideration must we give to the supply of these elements in our diet?

Before discussing the justification of the blood regeneration claims accorded iron and copper, it is important to point out that these elements are concerned only with hemoglobin formation. They have little to do with other blood constituents; even the red blood cells are only indirectly affected by these metals.¹ For example, in secondary or hypochromic anemia the body is unable to form sufficient hemoglobin, and the corpuscles decrease because they have no pigment to carry. When the amount of hemoglobin increases, the number of cells returns to normal providing there is no deficiency in the cell forming mechanism. In pernicious anemia the decrease in the cell count is the primary change, and the hemoglobin content decreases because there is an insufficient supply of cells to carry the hemoglobin. The mechanism of hemoglobin formation is not impaired in this form of anemia. We must keep in mind then that the supply of iron and copper affects only the hemoglobin content of

the blood and that the other changes observed are indirectly dependent upon the quantitative changes in the amount of pigment.

We must also remember that iron and copper are equally essential for hemoglobin formation although the quantitative requirement of each element may differ to a large extent. Since iron is a constituent of the molecule and copper acts only in a catalytic capacity, it is easy to see why more iron than copper is needed. I do not believe it is necessary at this time to discuss any of the divergent opinions which have been held concerning the specificity of copper. The necessity of copper as a supplement to iron has been demonstrated in so many different laboratories and with so many different animals that there can be no question about the requirement of copper for all red-blooded animals. It is also possible to refer to a number of clinical reports which demonstrate the necessity of copper for humans.

Copper cannot take the place of iron nor can it compensate for unavailable forms of iron. Copper functions only in the production of hemoglobin from the iron after it is assimilated.² Absorption and retention of iron and the conversion of iron into hemoglobin are two separate mechanisms. Studies on the availability of iron, therefore, should not be neglected because copper has been associated with hemoglobin synthesis. In order that active hemoglobin formation can take place the body must

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

contain definite quantities of both iron and copper. The actual amount which must be supplied in our diet each day to maintain a normal blood stream depends upon the rate of hemoglobin formation and the storage of the elements in the body. In rapidly growing infants there is a great demand due to the continual production of new blood. During the early suckling period this demand is satisfied almost entirely by the iron and copper present in the liver at birth, because the milk diet furnishes only small amounts of these elements. The supply in the liver is soon exhausted and unless additional sources of these elements are included in the diet anemia develops. Spectrographic analyses of livers from children, recently reported by Ramage, Sheldon and Sheldon,³ show that the iron and copper content of the liver falls rapidly during the nursing period and increases when a mixed diet is taken.

During the past 5 years we have studied the hemoglobin content of the blood of approximately 1,000 children brought to the child health centers in Madison.⁴ The results clearly demonstrate two facts: First, severe anemia is encountered in very few cases. It is only when all modern methods of infant feeding are completely disregarded and a diet of milk alone continued for 5 to 6 months that exceedingly low hemoglobin readings are obtained. Second, a slight anemia is found to be present in a large percentage of well fed children. At present I am unable to make any statement concerning the seriousness of these subnormal values. However, Miss Mackay⁵ has reported similar results for children in London and has correlated the prevalence of children's diseases with a low hemoglobin content of the blood. Kato and Emery⁶ also state that there must be some relation between the low hemoglobin content of the blood and the degree of resistance against invading

microorganisms. During the past year we have studied the effect of supplying additional iron and copper to the diets of a number of the children brought to the clinics. The work is still in progress, but the results to date indicate that the addition of these metals causes a definite increase in the hemoglobin in a very large percentage of the cases. In infants 5 months to 1 year of age the values increase from 10 to 11 gm. up to 12 to 12.5 gm. per 100 c.c. of blood. The latter figure appears to be the maximum value for infants of this age and readings above 12.5 gm. are seldom encountered even after feeding relatively large amounts of iron and copper. The maximum level increases with age, reaching values of 14 to 15 gm. when the individual is about 15 years of age. Thus, growing children are not only required to produce sufficient hemoglobin to supply the increasing blood volume but also to compensate for the increase in the normal hemoglobin content of the blood. I know of no comprehensive studies on the prevalence of anemia in children between the ages of 5 and 15 years, but from my meager experience with blood studies on college students I would not be surprised to find that many young adults have subnormal hemoglobin values.

Recent studies by Minot and Heath,⁷ Dameshek,⁸ and others have shown that hypochromic anemias are much more prevalent in adults than is generally supposed. In many of these cases the deficiency is due to an abnormality in the gastrointestinal tract preventing the proper utilization of iron. Even in cases of pernicious anemia treated with purified liver extract, the body's capacity for hemoglobin production may not be sufficient to allow a maximum rate of blood regeneration.

This short discussion of the demands for hemoglobin production clearly indicates that an anemia of low color index may be present, and is present to a

lesser or greater extent, in a large number of individuals. What is the best way to insure an adequate supply of iron and copper, which are known to be essential for hemoglobin production? If we are interested only in the simplest and cheapest method, there is no better way than to add simple iron and copper salts to our diet. We now have ample proof that inorganic salts can serve as the sole source of iron and copper.

In the laboratory⁹ rats have been raised from birth to maturity on cow's milk supplemented with iron and copper salts, together with a small amount of manganese, which is also needed to make milk complete. Second and third generation rats have been produced on this diet. Farm animals such as pigs and calves have been reared successfully on mineralized milk. During the past summer I had two students who lived on mineralized milk for 6 weeks. They consumed between 3 and 4 quarts of milk daily together with the proper quantities of iron, copper, and manganese. The only other food which they ate was one orange a day. The boys remained in excellent health and an actual increase in the hemoglobin content of the blood was observed during the experimental period. This not only demonstrates the completeness of a diet of mineralized milk, but it also shows that humans can rely on inorganic forms of iron and copper for hemoglobin production. Thus the entire iron requirement of one individual can be supplied at the cost of a few pennies per year, and the copper requirement can be satisfied for about one-tenth of one cent. Can we ask for a simpler method of insuring hemoglobin production? This does not mean that the entire problem of hemoglobin formation has been solved. I have said nothing about the organic precursors of the blood pigment, but from a practical point of view it is sufficient

to state that milk supplies these requirements. There is also much to be learned about the best forms and amounts of salts to be supplied. This can only be determined by long clinical experience.

In spite of the availability of such cheap forms of iron and copper most of us are not going to obtain our supply in this form. The fact is human beings have obtained their supply from foods for thousands of years before we knew these elements existed, and humans who are unaware that they need such metals will continue to obtain iron and copper from ordinary foods. However, if we are to rely upon foods alone for the maintenance of a normal blood stream we must know the limitations of each type of food and the methods of eliminating these deficiencies. The deficiency of milk in blood forming elements is universally recognized today and means are generally taken to compensate for the deficiency. In choosing foods to supplement those low in iron and copper we have used the total iron and copper content as the basis of our choice. In the case of iron we now know that this is not justifiable. We used to think that all food iron was readily available and utilizable. This is far from true. Food materials contain varying amounts of hematin iron and this form of iron cannot be assimilated. One mg. of iron supplied by wheat is not nearly as valuable as one mg. of iron supplied by a simple salt. The unavailability of a good share of the iron in many of the foods used in infant dietaries probably explains the prevalence of subnormal hemoglobin values observed in the children we have studied. Experimental work which we have conducted with rats during the past year¹⁰ clearly indicates that diets of milk and cereals or cereal products are decidedly deficient in blood forming elements. These diets are more deficient in iron than copper,

and a fair rate of hemoglobin regeneration was obtained by the addition of iron alone.

The maintenance of an optimum level of hemoglobin in rapidly growing infants is only possible if the demands on the liver iron and copper are reduced to a minimum by the early inclusion in the diet of foods rich in these elements. If an infant is born with a reduced supply, or if the supply is used up during the first few weeks of life, it is very difficult to reestablish a high level with food alone. The hemoglobin value can be increased to the optimum level in most children by supplying a small but definite amount of iron salts. I am of the opinion that a large number of children would benefit by the treatment. This does not mean that all children who do not receive this treatment would be severely anemic, but it would insure an optimum hemoglobin level which may be of great value in combating certain diseases.

The availability of the copper in different foods has not been studied. From a practical point of view this question may not be as important as the availability of iron because the requirement for copper is less and many foods which make up the bulk of our diet are relatively rich in copper. In many cases the hemoglobin building power may be restored to normal by the addition of iron alone, but until we are certain of an ample supply of available copper I feel it is wise to supply a small but definite amount of copper along with the iron.

So far I have discussed only the maintenance of a normal blood stream or the restoration of the blood when there is only a slight decrease in hemoglobin. When it becomes necessary to treat anemias with very low hemoglobin values, even foods considered to be rich in iron cannot supply enough to allow rapid regeneration. A number of workers have found iron salts to be superior

to liver for the treatment of these anemias. Iron salts are now used extensively for the treatment of hypochromic anemias. The question at present seems to be whether copper should be supplied. In these cases the demand for iron is so great that the requirement for copper may seem insignificant. It is also possible that the diet supplies the needed amount, but unless you can be certain of this fact the copper should be added. Dame-shak⁸ Mills,¹¹ Josephs,¹² and others have reported a number of cases which did not show a maximum response to iron until copper was added. If hemoglobin formation is actually retarded in some cases by a deficiency of copper, then the supply in many others must be close to the border line. This does not mean that we should recommend a wholesale use of copper salts, but that we should use standardized iron and copper preparations whenever there is a danger of copper deficiency.

In conclusion, we may say that diversified diets supply sufficient iron and copper for the maintenance of a normal blood stream in adults with normal hemoglobin requirements. For rapidly growing children and for adults with increased hemoglobin demands, many diets may be low in iron and possibly copper. The value of foods for supplementing diets low in iron and copper must be based upon the amount of available elements, not upon the total content. Diets deficient in blood forming elements may be rendered complete by addition of standardized quantities of iron and copper salts.

Child Labor Law of May, 1933, Egypt

A CHILD labor law of May 3, 1933, establishes a minimum age of 12 years for employment in factories, workshops, mines, and quarries, and in construction and transportation work. It does not apply to agriculture nor to home work in which only the members of the family are employed. However, children between the ages of 9 and 12 years may be employed in spinning, weaving, and knitting establishments and in other work "compatible with their age and physical ability." This provision is similar to a provision in a law of 1909 and in an order of 1931.

The new law limits the working day for children from 9 to 12 years of age to a maximum of 7 hours, exclusive of rest periods amounting to 1 hour. However, the law provides for the first time that in the case of children attending elementary schools the total hours of work, added to class hours, must not

exceed 7. For children between 12 and 15 years a maximum day of 9 hours is prescribed, exclusive of rest periods amounting to 1 hour. Children below the age of 15 years may not be employed between 9 p.m. and 5 a.m.; they must also be given a weekly rest of at least 24 consecutive hours.

The new law prohibits the employment of children below the age of 17 years in certain specified occupations, and of children below the age of 15 years in certain other occupations without a certificate from the public health officer as to their physical ability to perform the work. No person below the age of 17 may be employed without an identification card giving his name and age and bearing his photograph. The law is to be enforced by inspectors. Penalties are prescribed for violations.—*Journal Officiel du Gouvernement Egyptien*, June 26, 1933.

THE DEPRESSION AND HEALTH APPROPRIATIONS

TO ascertain the extent to which the present economic depression has affected the appropriations available to public health departments in the United States, questionnaires were recently sent out to the health officers of the 48 states and of the 108 largest cities in the country.¹ Replies were received from 36 states, aggregating a population of over 89,000,000 or approximately 71 per cent of the total population of Continental United States, and from 62 cities whose populations totaled 24,241,000, or about 61 per cent of the total population of the 108 cities questioned. It is believed that the results of the analysis of the data supplied by these health departments are fairly representative of conditions throughout the United States today.

In keeping with the general tendency to curtail expenditures in all governmental departments, there has occurred a sharp reduction of public health budgets. These reductions do not seem to have exceeded those connected with other governmental functions. Nevertheless, in view of the fact that appropriations for health conservation in most states and cities never have been adequate even in the best of times, it is felt that the continuation of the present tendency might jeopardize much of the progress made during the past two decades.

Of the 36 states which supplied the required data, 29 showed reductions in 1933 over 1931, ranging from 77 per cent in North Dakota to less than 3 per cent in Montana. Fifty-six cities reported similar reductions ranging from 47 per cent in Canton, Ohio, to 2 per cent in Richmond, Va. Seven states and 5 cities reported increases in public health budgets during this period, but for the most part, these were slight. One city, Nashville, Tenn., showed no change since 1931. The average reduction in the 29 states and 56 cities which reported reduced health budgets was about 17 per cent, slightly less in the states and a little more in the cities.

These figures represent net reductions between the appropriations of 1933 and the expenditures of 1931. In some cases, a small increase in one year was offset by a greater decrease in another year. However, there were 13 states and 44 cities which showed reductions in both years. Among these states, the total reduction since 1931 averaged 26.5 per cent; among the cities, 18 per cent.

Significant as are these figures, they nevertheless fail to portray the true gravity of the situation. Appropriations in 1933 cannot properly be compared with expenditures in 1931, for the reason that in many of the states and cities, 1933 revenues are almost certain to fall short of those anticipated; in which case, appropriations for health work will have to be scaled still further to enable these communities to maintain balanced budgets.

General figures, such as have been cited, however, cannot show how serious conditions are in certain sections of the country. For example, North Dakota in 1933 reduced its appropriation for health work from \$38,819 expended in 1931, to \$9,032 in 1933, a reduction of nearly 77 per cent; Mississippi showed a decrease from \$526,394 in 1931 to \$130,000 in 1933, about 75 per cent; Alabama, reduced from \$677,110 to \$436,954, or nearly 36 per cent; Virginia, from \$606,700 to \$404,215, or exactly one-third; and Ohio's health budget declined from \$323,273 to \$229,820, or 29 per cent.

Among the cities, the largest reduction occurred in Canton, Ohio, where the 1931 budget of \$40,527 was reduced to \$21,690 in 1933, or nearly 47 per cent; in Seattle, Wash., the health appropriation fell from \$667,202 to \$410,653, 39 per cent; in Birmingham, Ala., it decreased from \$98,591 to \$61,370, 38 per cent; and in each of the cities of Peoria, Ill., Flint, Mich., and New Haven, Conn., the reductions amounted to over 36 per cent.

In certain of these communities, the reductions represent principally cuts in salaries which have been absorbed by the staffs but in many cases they have also necessitated curtailment of essential activities and the scaling of personnel to mere skeleton organizations.

Hundreds of physicians, nurses, inspectors, clerks, and others specially trained in the technic and routines of public health work have been dropped. We have been most fortunate in that we have not had to contend with any serious epidemics during the past 3 years. If such an epidemic should occur as swept the country in 1918, it is not difficult to imagine the serious consequences which might follow with health departments in their present depleted conditions.

The worst feature of the situation is that many of the largest reductions have occurred in those communities which apparently have been the least able to stand them, considering the low per capita expenditures for health work in these places during past years. The cities and states which had good organizations have apparently learned the value of their investment in health work and have made only moderate reductions in their appropriations.

A further matter for concern is the fact that most of the private agencies interested in public health work, such as hospitals, clinics, public health nursing associations, etc., have suffered even larger cuts in their budgets than have been enumerated above respecting public agencies.

In view of all this, it is astonishing that the general health of the country has been maintained in such excellent state during the past 4 years. It is, perhaps, for this very reason that there has been such general inclination to reduce health expenditures during this period. We must not allow ourselves to be lulled by such seeming security. Undoubtedly, the present favorable state of public health is

REDUCTION IN HEALTH DEPARTMENT BUDGETS In Certain States 1931 to 1933

REDUCTION IN HEALTH DEPARTMENT BUDGETS In Certain Large Cities 1931 to 1933

very largely due to the momentum obtained in the past. Any appreciable let-up in our efforts would probably result in serious consequences.

In view of the present situation, it is recommended that the Association use all of the channels of publicity open to it to obtain the ear of the American people, and especially of those in authority, in order to stem the tide of further curtailment of health budgets. The Association must emphasize the fact that at the present time per capita health expenditures are in the aggregate running pretty close to \$.70 per annum; that such amounts are insufficient for adequate service, that at the first moment when economic conditions permit, the per capita health expenditure should be raised at least to the level of \$1 which prevailed in 1930; and that, thereafter, the communities should be encouraged to raise their budgetary allowances so that ultimately the standard declared by the Association to be essential, namely, \$2 per capita, may be realized. It is further recommended that in the interval the Federal Government be urged to take note of the situation of the local and state health services and make available through relief or other special appropriations such amounts as will help maintain health departments in good working order.

Finally, it is recommended that the Association coöperate in every way

EXPENDITURES FOR HEALTH 1931, 1932 & 1933

possible with other national organizations interested in public welfare, and further the campaign to maintain the health work of private agencies at their previous levels. At the present time, the reduction of appropriations for public health work has thrown enormous burdens on such private organizations as visiting nurse organizations, child health stations, tuberculosis clinics, etc. These organizations merit public support more than ever before. The community chests and other agencies engaged in the collection of funds for the support of these associations should receive the backing of health officers and other members of the American Public Health Association.

1. Report of the Committee on Stabilization of Health Appropriations (Louis I. Dublin, Ph.D., *Chairman*) of the American Public Health Association presented to the Governing Council at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

DOCTOR PARK NOT TO RETIRE

THE report current in New York City last month that Dr. Park would be retired from his position in the city health department on reaching the age limit, 70, in December attracted attention throughout the country. The leading newspapers in New York discussed the matter in their editorial columns and urged that steps be taken to secure Dr. Park's retention. Letters to the editor were

published praising Dr. Park's services and protesting against his retirement. A petition was circulated asking the Board of Estimate, in whose hands the matter lies, to continue Dr. Park in service.

An inquiry directed to the Department of Health discloses the fact that the law requires the retirement of all civil service employees when they have reached the age of 70. In order, however, not to lose employees whose services are still valuable to the city, the Board of Estimate is empowered to continue such persons in service after formal application for such continuance has been made. Dr. Park has not yet filed his application, though it is understood he is willing to continue in service and will comply with this necessary formality. On the part of the Department of Health there is no willingness to let so valuable a scientist as Dr. Park leave the service and when Dr. Park's application is forwarded it will, we are told, carry the strongest possible endorsement from Health Commissioner Wynne.

Inasmuch as all such applications must be acted on by the Board of Estimate, made up of the Mayor, the Comptroller, the President of the Board of Aldermen and the five Borough Presidents, no one is in a position to announce in advance what action will be taken. In the case of Dr. Park's application there is no reason to doubt that the Board will be heartily in favor of retaining Dr. Park in service. Because of the wide interest aroused by the matter, Mayor O'Brien has written to Dr. Park expressing the hope that Dr. Park will continue to give the city the benefit of his services. The Mayor has also assured him of hearty support when the formal application comes before the Board of Estimate.

It is gratifying to learn that the rumors of Dr. Park's retirement are baseless and that public health workers throughout the world are to continue reaping the benefits of the splendid work done under Park's direction in the laboratories of the New York City Department of Health. With so many important health problems demanding solution by laboratory methods, we can ill afford losing a man of Park's outstanding ability. We hope he will continue to aid us for many years to come.

AMEBIC DYSENTERY IN CHICAGO

AT the recent meeting of our Association in Indianapolis, a paper was read, which on account of its importance has been published elsewhere,¹ since it seemed advisable to get this before the public more promptly than was possible in a monthly journal. There is also a special article² and an editorial³ on the same subject.

Briefly, the facts are that during the summer an outbreak of amebic dysentery occurred in Chicago, and up to date, there have been 185 cases, with 19 deaths and 193 carriers of *Endameba histolytica*. The infection was traced to one of the prominent hotels which employed some 364 food handlers, among whom there were found 15 active cases and 11 carriers. A disquieting feature is that two food handlers who were discovered in the 1927 outbreak⁴ were also among those involved in the present flare-up. In 1929, 148 food handlers were examined, among whom 27 carriers and 2 acute cases were found.⁵ Some groups were especially hard hit. Of a committee which met in Chicago in June, 6 members developed colitis and 4 of them died. Three of these deaths have been proved to have been due to amebic dysentery. It is also stated that Texas Guinan, who died in the

West on a theatrical tour, was also a victim of this disease. The figures given prove conclusively that amebiasis was widely spread among the food handlers of this particular hotel. An attempt is being made to find out, through a questionnaire to 22,000 guests of the hotel chiefly concerned, approximately how many visitors to the Chicago Fair have been infected. Of 3,490 replies returned, 180 reported illnesses, of which 69 were diagnosed as amebic dysentery and 23 suspected of having the disease.

The lesson from this outbreak is clear; namely, the compulsory examination of all food handlers before employment and careful supervision of them afterwards. This is a difficult task, as food handlers are rather a migratory type, and especially at times when a city is crowded with visitors, as Chicago was during the World's Fair, large numbers of outside workers are apt to come in who later return to their homes. It is advised that those who have a history of amebiasis should be examined repeatedly for at least 4 months, and thereafter every 6 months for the rest of their lives.

Physicians and health officers throughout the country should be on their guard. The diagnosis of amebic dysentery can be made certainly only by a well equipped laboratory such as will be found in all of our cities and states. There is no doubt that amebiasis has been too prevalent throughout the United States, but with such a source of infection as has existed in Chicago with its millions of visitors during the past summer, fresh infections and further spread of the condition is inevitable, so that double precautions as to early diagnosis and increased vigilance for cases and carriers should be maintained in every state and city.

SENATE BILL NO. 1944

A BILL to prevent the manufacture, shipment and sale of adulterated or misbranded food, drugs, and cosmetics, and to regulate traffic therein; to prevent false advertisement of food, drugs, and cosmetics; and for other purposes.

Of this bill Dr. P. B. Dunbar of the U. S. Food and Drug Administration says:

President Roosevelt has ordered a complete revision of Doctor Wiley's famous "pure food law." The proposed new law, which retains all the worthy features of the Wiley act, modernized to meet present-day conditions, has already been introduced into Congress by Senator Royal S. Copeland of New York. It is identified as Senate Bill 1944 and will presumably come up for action early in the next session.

Dr. Wiley's pure food law provided protection to the consumer against food adulteration and misbranding. It covered conditions as they existed in 1906, and in spite of violent opposition at the time of its enactment has come to be accepted and appreciated today by the honest members of the very industries which it regulated. Times have changed and with the years the unscrupulous have

found ways of transferring matter from label to other means of consumer appeal. Cosmetics have come into a use totally unsuspected in 1906, and the present food and drug law has no control whatever over these products unless the manufacturer makes sufficient medical claims to permit their classification as drugs. As a result of all these changes there is today need for amending and enlarging the scope of the old law if consumer protection is to be maintained. There is need for more definite penalties and provision for methods of presenting evidence against the fraudulent if the enforcement officials are to be supported in their enforcement of public protection.

In brief, then, there is general recognition of need for change in the food and drug act and sympathy with the objectives of the present movement.

The question of support or opposition to Senate Bill 1944 is, however, more than a matter of sympathy with or opposition to the objectives of the protectors of consumer health. The bill states not only the objectives but the methods for attaining them. One may sympathize with objective and oppose the published method, and such opposition has been steadily developing since the industry and the public have had opportunity to study the wording of Bill 1944.

We do not regard this bill as an emergency measure in the sense of the measures that have been enacted to make business recovery and maintenance of homes and earning possible. It need not be "rushed" through Congress. Furthermore, the country's experience with the 18th amendment should be such as to counsel caution that a measure designed for the public welfare be one that will enlist the mental and moral support of the citizens concerned after enactment.

We appreciate that the only way to bring about a reform is to set up a plan of action. This has been done in the wording of Bill 1944. Given such a basis for further action, let every one in the American Public Health Association see to it that his representative in Congress knows his desire for the reforms suggested; but also let him know that we hold him responsible for a proper method of enforcement and for modification of the present wording wherever necessary to prevent its jeopardizing the very objectives sought.

In brief, we are for a revision of the present Food and Drugs Act to allow it to embrace control of cosmetics and of all media for presenting information about foods, drugs, and cosmetics to the public. We believe in giving our enforcement officials better tools for functioning. But we wish a law that will accomplish these ends, one that will be the true expression of what the consumer wants and needs. We solicit support for a bill but we ask that the bill be carefully framed even though to do so would necessitate extended conference and radical change in the phrasing of Bill 1944.

PASADENA IN 1934

THE Governing Council of the American Public Health Association has elected to hold the 1934 annual meeting in Pasadena, Calif.

At first blush, this seems a rash procedure, traveling appropriations being what they are for public health workers. The immediate reaction of many eastern members will be to settle back now and decide to miss attendance in 1934 in the hope that 1935 will bring the organization again within an overnight ride from their homes.

The philosophy back of the decision to go to the west coast next year may be briefly stated. The Association is a national society. It is just as far from the Pacific Ocean to the Atlantic as it is from the Atlantic to the Pacific. The far western members have not been taken into consideration by the national body since 1918; yet every year thereafter the registration records have shown representation from western states. It is fitting and proper now for eastern public health workers to reciprocate this support and travel to Pasadena in the fall of 1934 to join with the Western Branch in the celebration of its fifth anniversary.

The Committee on Meetings and Publications reminds the Association members that attendance at the Annual Meeting of their Association should not be dependent upon the ability of their organizations to finance their travel. Many of the most important figures in the public health world who have attended meetings consecutively for many years have never received a penny from any source toward their expenses. They have dug into their own pockets without question for the privilege and pleasure of attending the one national meeting that is strictly the possession of the public health profession.

It is the obligation of the Association this year to bring to Pasadena for the benefit of its western members the same excellent scientific program that has been arranged in recent years, with a cast of headliners, and the same distinguished audience. To this end every member of the Association who has attended Annual Meetings in the past can contribute, and the Association expects the support of its membership.

The Pasadena meeting is 10 months away. Travel to the west coast next fall will be less expensive than ever before. The most advantageous arrangements will be made by the Committee on Meetings and Publications. If special party fares will bring the cost per person down, special trains will be set up at convenient points. To members who know now that their departments and institutions cannot afford to send them to Pasadena the suggestion is made that they employ a method similar to the Christmas Clubs and Vacation Clubs so universally used by banks everywhere for the accumulation of small weekly sums, to provide a travel fund that will assure their presence at Pasadena for what should be and can be the most colorful, enjoyable, and profitable gathering of public health workers ever held.

ASSOCIATION NEWS

HAVEN EMERSON, M.D., PRESIDENT
EUGENE LINDSAY BISHOP, M.D., PRESIDENT-ELECT

*Haven Emerson, M.D.
President, A.P.H.A.*

*Eugene Lindsay Bishop, M.D.
President-Elect, A.P.H.A.*

FOR the past year the office of President of the American Public Health Association has been filled by John A. Ferrell, M.D., Director of the International Health Board of the Rockefeller Foundation. At the Indianapolis Annual Meeting, Haven Emerson, M.D., President-Elect, became President. Dr. Emerson has been a member of the Association since 1914, was a Charter Fellow, and is also a Life Member.

DR. BISHOP, President-elect, is a native of Davidson County, Tenn. He is a graduate of Vanderbilt University School of Medicine, 1914, and received his C.P.H. from Johns Hopkins School of Hygiene and Public Health in 1923.

He was field director of Tennessee State Health Department 1916-1918; director, division of rural sanitation 1918-1922; Assistant Commissioner of Health 1923-1924; and since 1924 Commissioner and Assistant Professor of Preventive Medicine at Vanderbilt University School of Medicine.

He is a Fellow of the American Public Health Association; member of Committee on Administrative Practice, and Chairman of Sub-Committee on Rural Health Work; served for past 2 years as Chairman of Executive Board and a member of the Governing Council; was Secretary, and later Chairman, of the Health Officers Section. He was instrumental in the organization of the Southern Branch of the Association and

was elected President at its initial meeting in 1932.

Dr. Bishop was formerly a member of the Board of Scientific Directors of the Rockefeller Foundation, and is at present Chairman of the Committee on Federal Relations of the State and Provincial Health Officers and Committee on Standards of Qualifications for Local Health Officers of State and Territorial Health Officers.

He is a member of the Tennessee State Medical Association; Nashville

Academy of Medicine; American Medical Association (formerly Secretary, and later Chairman, Section on Preventive and Industrial Medicine of this Association); Southern Medical Association; National Malaria Committee (Chairman 1932); American Society for the Advancement of Science; American Social Hygiene Association; American Child Health Association. Member Alpha Omega Alpha, Alpha Kappa Kappa, and Delta Omega honorary fraternities.

SECTION RESOLUTIONS

ADOPTED AT THE INDIANAPOLIS ANNUAL MEETING

Vital Statistics

DEATH OF EDWIN W. KOPF

RESOLVED, that in the passing of Edwin W. Kopf, Charter Fellow of the American Public Health Association, the Section on Vital Statistics recognizes the loss of an honored member and acknowledged leader, who contributed invaluable services to the statistical study of mortality and morbidity. Mr. Kopf's ability and energy, together with his intellectual honesty and keen critical faculty in interpreting statistical data were qualities which not only inspired the admiration and confidence of his co-workers in the American Public Health Association, but which earned recognition abroad; and be it further

RESOLVED, that the Secretary be instructed to extend to his widow, Anna Belle Kopf, this expression of the high regard in which the members of the Vital Statistics Section of the American Public Health Association held Mr. Kopf's lovable character and fine scholarship; and be it further

RESOLVED, that in behalf of the Section, the Secretary be instructed to extend to Mrs. Kopf its deepest sympathy in her irreparable loss.

COMPLETION OF REGISTRATION AREA

The Section on Vital Statistics of the American Public Health Association recognizes with gratification that the Registration Areas for births and deaths have now become co-extensive with the continental area of the United States. This achievement is the culmination of 50 years of effort initiated by Dr. John Shaw Billings; ably continued by Drs. William A. King, Cressey L. Wilbur, and William H. Davis; and brought to a successful culmination by the present incumbent, Dr. Timothy H. Murphy, therefore be it

RESOLVED that the Section on Vital Statistics offer its congratulations to the Bureau of the Census, that Vital Statistics, the foundation of sound public health activity, have finally been placed upon a nation-wide basis, and be it further resolved that the Section expresses its appreciation to the agencies and individuals who have made this achievement possible.

COÖPERATION INVITED FROM UTAH

WHEREAS, the Registration Areas of the United States for births and deaths have now been completed, making

possible for the first time the publication of vital statistics on a nation-wide basis, and

WHEREAS, the complete realization of this objective is now made impossible only by the absence of returns from the State of Utah from January 1, 1932, to date, be it

RESOLVED, that the Section on Vital Statistics of the American Public Health Association appeal to the Honorable Henry H. Blood, Governor of the State of Utah, for coöperation with the other 47 states of the Union, in the prompt transmission of certificates of births and deaths to the Bureau of the Census.

PUNCH CARDS VERSUS TRANSCRIPTS

WHEREAS, definite decision has been made by the Bureau of the Census to accept punch cards from the New York State Health Department in lieu of transcripts of death certificates, and

WHEREAS, this action is, in effect, acceptance by the Bureau of the Census, for inclusion in its annual mortality reports, of the classification of certified causes of death by the New York State Health Department instead of by the Bureau of the Census, and

WHEREAS, the New York State Health Department (Division of Vital Statistics) is, for the present, in the unique position of having in charge of this important branch of its work the very man who, over a long period of years, had the same responsibility in the Bureau of the Census, and

LABORATORY LETTERS OF INTEREST

THE Laboratory Section archives were enriched during the Indianapolis meetings when Professor E. O. Jordan, one of the organizers of the Section although now—because of

WHEREAS, the New York State Health Department thus enjoys an advantage which should enable it so to classify the causes of death that the resulting death rates for the individual causes of death should closely approximate those which would result if the classifying were done in the Bureau of the Census. Now, therefore, be it

RESOLVED, that in view of the unique position of the New York State Department of Health, as hereinbefore noted, *and for that reason alone*, it is the sense of the Vital Statistics Section of the American Public Health Association that acceptance of that state's coding of the causes of death will not materially affect the comparability of New York State death rates with those published in Census Mortality volumes in the past, and be it further

RESOLVED, that it is also the sense of this Section that state health departments, in general, do not have the trained personnels requisite for this work; and that years of training would be required to bring them up to the standard of efficiency which obtains in the Bureau of the Census, and be it further

RESOLVED, that it also is the sense of this Section that the extension to other states of the practice of accepting punch cards would constitute a dangerous threat to the integrity of statistics of the individual causes of death, unless it be found practicable to have the editing staffs of the states work under the direct and continuous supervision of trained Bureau of the Census coders for a period of years.

changing interests—a member of the Epidemiology Section, furnished the Section with three letters written to him in 1899 by Dr. Wyatt Johnston of Montreal, Que., pertaining to the formation of what was then called the

Laboratory Committee of the American Public Health Association but which became the Laboratory Section. By vote of the Section Council these letters were read before the well attended luncheon session of the Section on Wednesday, and greatly interested all present. A motion was made by Dr. Lillian South of Louisville, Ky., and seconded by Dr. G. F. Reddish of St. Louis, Mo., that the originals of these letters be preserved among the section records and that a letter of thanks be sent to Dr. Jordan for his courtesy and thoughtfulness in furnishing these documents to the Section.

One letter is typewritten and signed by Dr. Johnston, requesting Dr. Jordan to become a member of the "Laboratory Committee." It mentions that Professor Welch of Johns Hopkins has consented to act as honorary chairman, and urges that Dr. Jordan's studies on the effects of the drainage canal be a motive for a preliminary communication at the meeting in Minneapolis in November, 1899. Dr. Johnston interestingly promises if the presentation is

made to "see as far as possible that any men from St. Louis who wish to take part leave their revolvers outside and employ as far as possible parliamentary language." The second is a circular letter, but signed by Dr. Johnston, requesting applications for membership and titles of papers for the first meeting. The third is a letter in Dr. Johnston's handwriting thanking Dr. Jordan for his contribution in advance of the meeting.

Several of those who heard the letters read expressed interest that the object of the formation of the Laboratory Committee, as expressed then by Dr. Johnston was "to unite the sanitary laboratory men in the Continent in some manner which will secure us the means of discussions coöperative of research, etc., besides a communication of our individual results."

The hope was expressed that others who have interesting old documents in their possession will be prompted by Dr. Jordan's action to submit them to the secretaries of any sections concerned.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

Antonio Luis de Barros Barreto, M.D., D.P.H.,
Caixa Postal 251, Bahia, Brazil, S. A., Health
Officer, Federal Department of Public Health
(Associate)
Wedford W. Brown, M.D., City Hall, Athens,
Ga., Commissioner of Health, Athens and
Clark Counties
Fratris L. Duff, B.S., Department of Public
Health, Lawton, Okla., Health Officer
Daniel V. O'Leary, M.D., 315 Delaware Ave.,
Albany, N. Y., Health Officer

Laboratory Section

Lewellyn S. Dibble, B.S., 78 Nilan St., Hart-
ford, Conn., Director of Laboratory, Bryant
and Chapman Company

Renwick H. Leitch, M.A., Dairy Research
Labs., Auchincruive Ayr, Scotland, Professor
of Dairying, West of Scotland Agr. College
(Associate)

Victoria Orner, B.S., 111 N. Monroe St.,
Sturgis, Mich. (Associate)

William A. Starin, Ph.D., Dept. of Bac-
teriology, Ohio State University, Columbus,
O., Professor of Bacteriology

No. 1, State Department of Health
 I. Franklin Miller, P.O. Box 133, Pittsburgh, Pa. (Associate)

Willa Murray, B.A., 1343 H St., N. W., Washington, D. C., Assistant to Director, National Committee on Federal Legislation for Birth Control

Public Health Nursing Section

Beatrice I. Hamel, R.N., 335 Huntington Ave., Suite 32, Boston, Mass., City Public Health Nurse.

Esther M. Latimer, R.N., 26½ E. Main, Danville, Ill., Supervisor, Child Welfare Assn.

Charlotte E. McGee, R.N., P.H.N., 1625 Appleton St., Long Beach, Calif., Public Health Nurse, Tuberculosis Assn.

LETTER TO THE EDITOR

TO THE EDITOR:

In the October, 1933, issue of the *American Journal of Public Health* appeared a letter to the Editor from G. M. Mackenzie, M.D. suggesting that the laboratory "standards" used in *Community Health Organization* are too low, and also that "contacts and the correlation of the clinical aspects of public health work and laboratory diagnosis can be achieved far more successfully if the director of the laboratory is a graduate in medicine." Before publication, Dr. Mackenzie courteously sent me a copy of this letter, but circumstances prevented a reply until now. Such communications are welcomed because of the value of exchange of viewpoints in the line of progress.

Although the "Estimates" or so-called "Standards" given are not those of the editor, but of the Sub-Committee on Appraisal of Municipal Health Work of the Committee on Administrative Practice of the American Public Health Association, the following comments are offered. It has been a guiding principle of the Appraisal Committee to set standards not beyond the attainment of all cities but at a point which is actually

reached by a quarter of the cities. They are not "ideal" or "maximum," and perhaps for some cities not even "adequate" standards. They are, however, practical working standards proved by experience to be well within the range of attainment. The standards used in *Community Health Organization* were based on the 1929 edition of the *City Appraisal Form*, and these standards were in turn based on the actual experience in cities immediately prior to this.

The laboratory section of the *Appraisal Form*, during the 1929 revision, was submitted to a committee appointed by the Chairman of the Laboratory Section of the A.P.H.A. and the members gave much consideration to the items, and recommended revisions which were incorporated. The "specimen" was adopted as the unit in place of the somewhat indefinite term (with varying interpretations) "examination." Specimen was defined as "similar material submitted to a laboratory in a single container from a single source. A note attached to the item "6,000 examinations per 100,000 population" read: "The grand total of specimens and ad-

ditional reported results. Credit will be granted only for work actually done in *local laboratory maintained by the community.*"

Laboratory service has increased since 1929 and the new edition of the *Appraisal Form* (1934) will undoubtedly recognize this fact. From such data as are available, it would appear that the services now rendered in New York State, as shown in Dr. Mackenzie's table, are greater than throughout the country generally. Thus it is probable that even with the raising of standards in accordance with increased service generally, the actual standards set in the new *Appraisal Form*, in accordance with the principle of adjusting them to the point which is exceeded by the upper quartile of cities, will still not be as high as some of the figures given by Dr. Mackenzie.

Relative to the need for a graduate in medicine as a laboratory director, conditions vary. The degree is far less important than the ability, personality, and training of the individual in charge. Considering practical problems throughout the country, it is my belief that cases are rare where a medical director of a public health laboratory is needed in a city of 200,000 population or less. The medical degree may be an asset but rarely an essential if the laboratory director has sufficient medical contacts to comprehend the significance of his work. There are many cities and counties, and even some states, where the public health laboratory is efficiently directed by a non-medical person and where the physicians regard highly the laboratory service.

Very truly yours,
IRA V. HISCOCK

Members and Fellows of the A.P.H.A.

WHY PAY ANNUAL DUES?

IF you dislike the bother of paying membership or Fellowship dues each year, or

IF you are one of those absent-minded people who have to be reminded again and again of unpaid dues, or

IF you are thrifty, *then you should apply for*

LIFE MEMBERSHIP in the A.P.H.A.

Write to the Committee on Fellowship and Membership of the American Public Health Association for information regarding this form of membership.

PUBLIC HEALTH ADMINISTRATION

Milbank Memorial Fund — The twenty-eighth year of the Fund's activities was characterized by somewhat increased emphasis on the larger aspects of public health and social welfare.

The Fund's previous experience in health demonstrations and in conducting or aiding in various experimental public health and related projects has strengthened its belief that public health, as a social function, is concerned not only with direct measures for the prevention of disease and the education of the public in hygiene, but also with the medical care of the sick, the proper administration of relief, and with the prevention of all conditions that are harmful to health, whether they be economic, social, or more directly etiological. In this course, the Fund has been aided by the wise advice of its various boards of counsel and by the coöperation of a number of voluntary and official agencies, local, state, national, and international.

In connection with the Bellevue-Yorkville demonstration in New York, many of the services developed within the area have been extended to other parts of the metropolitan district; the policy of district health administration through health centers has been adopted, and a program of district or decentralized health administration has been decided upon. The Fund has conducted studies aimed at finding out how existing public health procedures can be made more effective through increased efficiency of personnel and by more careful selection of individuals.

Coöperation is being given the U. S. Public Health Service in a consideration of the health problems of adult life; in a scrutiny of public health procedures, especially in nursing, maternal, infant, and child hygiene, tuberculosis and communicable disease control, and in the treatment of syphilis. Support is also extended to the International Health Organizations of the League of

Nations in a study of the effect of the depression on health. Among the research studies in which coöperation is being given are the extent to which birth control is practised in families of different economic and social class and the effectiveness of different methods; the coöperation on syphilis research with the medical schools of The Johns Hopkins University, Western Reserve University, University of Pennsylvania, University of Michigan, and the Mayo Clinic; in the maintenance of a school of nursing in the Syracuse University Medical School; in research on rheumatic fever in the Yale University School of Medicine.

The Fund is financing and technically assisting a unique and noteworthy public health experiment in a typical rural area of China, which is being conducted under nonpolitical auspices, and is coördinated with the agricultural, industrial, and educational program of the Chinese National Association for the Mass Education Movement. Technical assistance was given to the President's Research Committee on Social Trends in the preparation of that committee's notable report, and financial aid was given to various health, social welfare, and educational projects of such organizations as the New York Academy of Medicine, the Association for Improving the Condition of the Poor, the Henry Street Settlement, the East Harlem Nursing and Health Service, and the Judson Health Center.

Kanawha County, W. Va.—The seventh annual report of the county health unit for the year ending June 30, 1933, emphasizes the value of artificial immunization against diphtheria, small-pox, and typhoid. Most of the phy-

sicians in the county, especially those on contract with coal companies, do most of the immunizing in their communities. Many of the coal companies accepted the recommendation of the health unit to require that anyone moving into their houses submit to artificial immunization of all members of their families unless previously protected. During the year there were given 8,366 immunizing treatments against typhoid, 5,677 against diphtheria, and 4,059 against smallpox. There was no smallpox during this period. The county employs a physician to attend to the medical care of prisoners, inmates of the county infirmary, and indigent cases.

Public health education is stressed, and the health unit is supported in this program by the school authorities, the Women's Clubs, the 4-H clubs, insurance companies, and milk companies, as well as by the medical profession. The disaster committee of the American Red Cross gave special assistance in flood relief work.

Syracuse, N. Y.—The year 1932 marked the 100th anniversary of the formation of the board of health for the community which later became known as Syracuse. In the U. S. Chamber of Commerce Health Contest, Syracuse shared honors for first place in 1932 with New Haven in the population class. At the medical dispensary, over one-fourth of the 81,000 visits were made by persons applying for medical aid for the first time, and since 1929 the number of dispensary cases has increased 40 per cent. In addition, the 6 physicians employed by the Department of Health to make home calls upon the indigent sick, during the year, made 12,000 such visits, or over twice the number made in 1931, and nearly four times the number made in 1930. Outbreaks of measles and whooping cough required 21,963 home calls by nurses in contrast with 8,281 in 1931. In pre-

natal clinics, over 1,000 new cases were registered—or double the 1929 enrollment. The known cases of tuberculosis numbered 1,529 as compared with 1,445 in 1931.

In spite of these increases, economic circumstances caused the closing of one tuberculosis clinic with a reduction of weekly sessions from 8 to 5; and the reduction of child welfare clinic sessions by over 100 for the year. Other important personnel cuts, including the bureau of health education, are noted. The staff was reduced from 153 persons in 1931 to 129 in 1932, with a budget reduction of approximately \$50,000. The *esprit de corps* of the employees is praised and reference is made to volunteer assistance. Services were rendered by the welfare division of the Federation of Women's Clubs in well baby clinics, by the Junior League at the medical dispensary, by Mothers' Clubs, and by the Onondaga Health Association in promoting health educational activities, as well as by the Public Health Committee of the Syracuse Academy of Medicine.

Among other worth while experiences which have so far come out of the depression adjustment service should be mentioned the real advantages of the consolidation of infant and preschool clinic services, as well as the consolidation of the food and sanitary inspection services. On the other hand, half-time nursing service cannot be called a success and should be corrected as soon as possible. A proposal advanced during the early part of the year to permit the sale of raw milk directly by the farmer was definitely vetoed. In fact, an amendment of the sanitary code, prohibiting the sale of any raw milk other than certified, was the final outcome which left the Bureau of Food Inspection in a stronger position.

Montclair, N. J.—In 1932 this city of 44,572 population expended through its health department \$1.12 per capita. Of the total deaths, 56 per cent occurred among persons 60 years of age or older, 16 per cent being 80 years of age or over. There were 124 deaths from dis-

eases of the circulatory system, 47 from cancer, and 31 from tuberculosis. The low infant mortality rate of 38 is noteworthy.

A physical examination was made of each school pupil, including eyes, ears, teeth, tonsils, chest, heart, posture, and general mental aptitude. Each student was also weighed and measured. Children with physical defects were followed up and more coöperation than previously was enlisted from the family dentist and physician. Physical examinations were also made of 980 food handlers.

During the year, 2,000 families received some form of public health nursing service in their homes. This represented some 5,000 individuals with a total of 32,956 nursing visits or an average of 13 visits per day per nurse. There were 10,137 clinic visits of various kinds. The nursing service includes all follow-up work from the prenatal and post-partum clinics and ward maternity cases of the hospital. The nursing bureau also investigated all calls coming to the Department of Public Welfare for physicians.

Standing orders have been received from the town physician for patients under his care, which are carried out by the nurses, and many times eliminates the necessity for a call from him thereby decreasing the cost of medical care.

National Society for the Prevention of Blindness—Progress in the program designed to eliminate the principal diseases causing blindness and to reduce eye injuries to a minimum is shown in the Society's Annual Report, entitled "Twenty-Five Years of Saving Sight." The report discloses a growth of membership from the 10 public-spirited men and women who organized the Society a quarter-century ago to 16,600 members throughout the United States; it discloses, also, that activities have been extended, in collaboration with the medical profession,

the field of education, organized labor, the safety movement, social work, governmental agencies, and other groups. The report says:

Throughout the past year the National Society for the Prevention of Blindness has had evidence that the economic crisis will have its effect on the eyesight of the future. The Society believes it has reached a high level of accomplishment in a depression year, when every economy was required. The organized movement began in 1903 as a campaign in New York State against blindness from ophthalmia neonatorum. It evolved into a nation-wide movement in 1915 when the New York State Committee for the Prevention of Blindness became a national committee. As a result of adoption of laws, in most states, requiring doctors, nurses, or others in attendance to put prophylactic drops in the eyes of babies at birth, and the constant educational activities of the Society, the frequency of ophthalmia neonatorum as a cause of blindness among children admitted to schools for the blind has diminished each year until now it is approximately 75 per cent less than in 1908. Complete eradication of this source of blindness—once the most prolific of all causes—is regarded as scientifically possible.

Another aspect of the movement is the work of "sight-saving classes" for the education of partially-seeing school children. In these classes, children with seriously defective vision are provided with books in large type, good lighting and specially trained teachers; the children are given an opportunity to receive an education and vocational guidance, while their remaining vision is conserved. The number of classes has increased from the 2 established in 1913—one in Boston and one in Cleveland—to 421 now maintained in 121 cities throughout the United States. Despite the depression, 15 new sight-saving classes were established in 1932; the most recent being one planned for Waikiki, Hawaii. The report points out, however, that

... there are still 45,000 children in the United States who have such seriously defective vision that they cannot receive their education in the regular classes, but should be in sight-saving classes.

In its campaign against the eye hazards of industry, the Society coöperates with state labor departments, industrial journals, insurance companies, trade associations, universities and vocational schools, safety engineers, and others professionally concerned with industrial accident and health problems. During the past year the Society sought, particularly, to arouse the public against dangerous fireworks and toy firearms, which constitute serious hazards to children. A survey conducted by the Society revealed that many children lost their sight as the result of accidents while playing with such toys.

Some communities have laws regulating the sale of fireworks, but there is great laxity throughout the country in enforcing these laws. The Society has secured the coöperation of governors, mayors, local safety councils, and influential citizens, generally, in its effort to stamp out this menace to childhood. While legislation is necessary, the major responsibility rests with parents and teachers. The publication of *Eye Accidents in Child Play* crystallized sentiment on this subject and resulted in additional and more stringent laws in some cities.

The report points out that special clinics have been established in New York, Philadelphia, and Cincinnati for cross-eyed children whose parents cannot afford the long and expensive treatment under the care of a private physician.

While it may be too soon to forecast the success of the work being done in these centers, it is hoped that it will prove an added accomplishment in the program of saving sight. It seems almost inexcusable that there should be any children left with cross-eyes, when we realize that it is an affliction which usually can be corrected early in life. "The cross-eyed child is frequently a behavior problem because he is self-conscious and suffers from a sense of inferiority. Unfortunately, it is popularly believed that cross-eyes can be outgrown. Parents often neglect to have the

defect in their children's eyes corrected until too late to avoid the physical or psychic involvements. The Society is striving to inform parents, through popular literature, lectures, and the newspapers, of the urgency of early treatment for the young cross-eyed child."

Ministry of Health, England—Annual reports of the chief Medical Officer of the Ministry of Health of England abound in information and stimulating discussions of much value to health administrators. The 1932 document is no exception to this rule. The statistical tabulations are models of completeness and accuracy.

During the last 40 years of the 19th century, infant mortality in England and Wales was almost stationary, but in the present century it has been reduced by more than half. The decline is greatest at 3–6 months and least in the first month of life. The most important decline in recent years was in bronchitis and pneumonia and in diarrhea and enteritis.

Speaking generally, the infant mortality rate is highest in the county boroughs and in the north of England, and the decline has been greatest in the small towns and in London.

A table shows the deaths recorded by individual years since 1900, the number which would have been recorded, had the rate of mortality observed over 1901–1910 still prevailed, and the difference. Hence, in 1932, in this area of 39,988,000 people, there were 39,933 infant deaths, with 38,655 less deaths than if the earlier rate had prevailed.

It cannot, I think, be doubted that this is to a large extent due to increased maternal care of the new-born child. There has, of course, been an improvement in the external environment of the child, sanitary, social, and domestic; but after all is said about the influence of external improvements, it has to be remembered that the "environment" of an infant under 12 months of age is mainly its mother. . . . With a declining birth rate it may be said that it is imperative that the nation should save the newly-born if it is to sustain the population; but on the con-

trary, it may also be held that it is futile to save these lives unless they be properly reared and equipped for healthy and productive citizenship. Merely to save life, or merely to prolong it, is not enough.

In discussing the question of unemployment and national health, the author notes that any long sustained physical pressure or stress of serious degree represents itself ultimately in a rise in mortality, particular or general. He emphasizes the importance of observing the secular, or century, trend in physical evolution of a race and the need to cultivate a historical sense. Of two facts, he says, we may be sure. First, there is taking place a great improvement in the physical condition and health of the people—life is longer and its physical character is better than in former centuries in England. Second, he indicates that "We possess, for better or worse, a more sensitive humanitarianism for human pain and distress than formerly, and fuller means of expressing it."

Reference is made to the health insurance service in which 16,000 doctors are at the medical service of 16 million persons over 16 years of age, with cash benefit, medical and disablement benefit, and a series of additional benefits for dentistry, nursing, etc. Where, by failure to pay contributions due to unemployment, these persons may cease to be entitled to the insurance medical benefit, they can, in their need, have recourse to the public assistance medical service which is to a large extent rendered by the same medical practitioners as serve on the panel. Some 8 millions receive such benefit every year.

Though unemployment itself seems to be an unmixed evil, it must not be forgotten that in innumerable instances the unemployed person has more fresh air, exercise, rest, and freedom from industrial risks and restrictions than fall to his lot when he is employed. Again, the community, as compared with pre-war years, has realized the health and economic advantages of increased sobriety. Lastly, there is the ever-spreading practice of per-

sonal hygiene in dietary, clothing, exercise, cleanliness, and an open air life, which is rendering an immeasurable profit in life and health to the population as a whole.

Baltimore, Md.—In the 118th annual report of the Department of Health, 1932, the departmental organization is set up in three sections—administrative, medical (including nursing and dental), and sanitary. Vital statistics, public health education, and health district work are included under administration. There are 13 consultants to the department, this board having been appointed in 1932. An air view of Baltimore and the eastern health district adds interest and serves to orient the reader in considering the new district development. The district comprises the 6th and 7th wards, and includes a population of some 60,000 people, of whom 21 per cent are colored and 13 per cent are foreign born. Other accomplishments of the year included the completion of a health and hospital survey by the U. S. Public Health Service, the establishment of a satisfactory relationship with the public health committee of the city medical society, and the clarification and extension of several important services.

The health of the city, as reflected in statistics, was good in comparison with other years. A general death rate of 13.1 and an infant mortality rate of 62 were new low records. In the field of public health education, notable progress was made. The *Baltimore Health News*, issued monthly, reached some 8,875 readers. There was inaugurated a permanent radio health service. Negro Health Week was featured. The coöperation of 50 motion picture houses was enlisted to show during the diphtheria prevention campaign a trailer which was viewed by a half million people. There were also shown 35 other motion pictures to audiences totalling nearly 12,000. Demonstrations, exhibits, round-table

discussions, and a health contest were included in the program. Some 724 newspaper articles were prepared (6,771 column-inches devoted to public health), and 815,086 pieces of health literature were distributed to 89,540 persons.

The health district project, first proposed in 1921 by Dr. William H. Welch, was launched during the year. Co-operating with the health department and the School of Hygiene were several voluntary health agencies including the Babies' Milk Fund Association and the Instructive Visiting Nurse Association.

Among the purposes of the development are: The furnishing of facilities for the systematic training of health officers, public health nurses and other workers who might be employed by official or nonofficial agencies conducting public health activities in the city, of pupil nurses in hospital training, and of students of public health; as well as the making available of a field for more precise and instructive study of numerous public health problems, both administrative and epidemiological.

Canadian National Committee for Mental Hygiene—The report of a survey made of this organization in 1932 by the Canadian Medical Association reveals in an enlightening manner the stages of development, and the extent of present services, and provides recommendations for future guidance of committee work. Caution is expressed to prevent the work from becoming too diffuse, and it is suggested that the National Committee study public health services in Canada, particularly as they apply to municipalities and counties, with a view to the inclusion of mental hygiene in public health and the raising of standards of official health services.

The National Committee needs to determine its program for mental hygiene as part of public health, and, at the same time, to consider the standards of public health service, for it can be expected that mental hygiene will be effective in public health in proportion

to the effectiveness of the whole, this in turn being dependent upon the standard of public administration established.

The report contains a detailed plan, or proposed organization, for the future which divides the work into 8 divisions and provides for four permanent committees, including education, research, service, and public administration. The first of 16 specific recommendations urges that the committee promote the training of mental hygiene leaders, and undergraduate instruction for professional workers; and that they give particular consideration to instruction to undergraduates in medicine, to nurses and teachers in training, and to physicians and nurses who are preparing for public health work.

Suffolk County, N. Y.—In the fourth annual report of this county department of health, reference is made to the supervision of 450 boarding homes, requiring the full time of an inspector who makes quarterly inspections in accordance with law. These homes bring an income to their operators of some \$125,000 a year. There were also 29 licenses refused during the year. Maternity homes are likewise supervised and licensed.

Sanitation receives much attention in the county, including sanitary surveys of private wells, public water supplies, Huntington Harbor and Lake Ronkonkoma. Public health nurses are assigned to townships for generalized services, although bedside nursing is done only in case of emergency or for demonstration. The health department budget for the year ending October 31, 1933, was \$86,000 for a population of 166,205 (1931). An infant mortality rate of 50, a birth rate of 15.4, and a death rate of 16 are recorded for the year 1931, including institution figures.

LABORATORY

RAPID AGGLUTINATION TECHNIC APPLIED TO *B. PERTUSSIS* AGGLUTINATION

PEARL L. KENDRICK, Sc.D., F.A.P.H.A.

*Associate Director, Bureau of Laboratories, Michigan Department of Health,
Western Michigan Division, Grand Rapids, Mich.*

WHEN first using the agglutination reaction in testing cultures of *B. pertussis*, the usual technic was employed. Five tenths c.c. of each serum dilution was mixed with 0.5 c.c. of culture suspension and the mixtures incubated at 55° C. for 4 to 5 hours and then placed at room temperature. Readings were made at the intervals selected by Leslie and Gardner¹—at 4½ hours—and again after the tests had stood over night. Considerable difficulty was experienced in the interpretation of results because of the tendency of *B. pertussis* suspensions to settle out in a somewhat mucoid clump after standing for a time. Differentiation of this non-specific factor from true agglutination was not always easy and end-points were indefinite. It seemed possible that the rapid agglutination technic devised by Miss Noble² might overcome the difficulty since the readings would be made before the suspensions had an opportunity to settle. Only a few series of tests were needed to demonstrate the superiority of the procedure, and it is now used exclusively in our study of *B. pertussis* agglutination. The details of the procedure follow:

Antigen—The 48-hour growth of *B. pertussis* on a Bordet-Gengou slant is transplanted to a half Petri plate of Bordet-Gengou medium. After 48 hours' incubation, the growth is removed with a stiff, bent needle and emulsified in 1½ c.c. of physiological salt solu-

tion. The suspension is filtered and adjusted, if necessary, to a turbidity of approximately 10 billion organisms per c.c. by comparison with a standard.

Filtration is an important step in obtaining satisfactory, smooth suspensions. Test tube filters are prepared for this purpose. A thin layer of moistened cotton is shaped around the finger, placed on a simple copper wire netting support, and inserted in a 5 by 5/8 tube, the free end of the wire strip being bent to hook over the lip of the tube. The cotton is molded against the walls of the tube by means of a wooden applicator. These filter tubes are

plugged with cotton and sterilized. The filter is easily removed after use and the plug reinserted. The accompanying photograph shows the filter support and the completed test tube filter.

For a larger filter, a layer of gauze and cotton is wrapped around the outside of a square of wire netting cut from a bias strip and shaped to fit inside the neck of the bottle or flask of the desired size. The filter is suspended by two wires which cross under it, pass through the netting, and are hooked over the lip of the flask.

Antiserum—For preparation of a diagnostic serum, a rabbit is injected intravenously with a 10 billion per c.c. suspension prepared from a 48-hour growth of a recently isolated *B. pertussis* culture to which merthiolate 1:10,000 has been added at least 24 hours previously. The injection doses are 0.4 c.c., 0.8 c.c., and 1.0 c.c., respectively, at 3- to 4-day intervals. About 1 week after the last injection, the agglutination titer (equivalent, as explained below) has been around 1:20,000 in the six different rabbits treated by this method. The serum dilutions for agglutination tests are chosen according to the particular conditions. For testing cultures isolated by the cough plate method, the dilutions usually employed are 1:10, 1:100, 1:500, 1:750, 1:1,000, 1:1,500, and 1:2,000. For uniformity, the same dilution scheme is always employed and separate pipettes are used for the different dilutions.

The agglutination test—One-tenth c.c. of each serum dilution is mixed with 0.1 c.c. of antigen, the measurements being made with one c.c. pipettes graduated in tenths. For an antigen control, 0.1 c.c. of saline is mixed with 0.1 c.c. of antigen. The mixtures are shaken by hand for 3 minutes. For the shaking process, the racks are rocked at the rate of approximately 60 back-and-forth motions per minute and in such a way that the contents flow up the walls of

the tubes for about three-quarters of their length. After the shaking period, physiological salt solution is added for greater ease in reading. Because of its convenience, the Hipple pipetting apparatus, used in the Kahn test and set to deliver 0.5 c.c. of saline, is ordinarily employed.

Reading the tests—The tests are read immediately after the addition of saline and each tube recorded as —, \pm , +, ++, +++ or ++++, according to the degree of agglutination. In the interpretation of the results in comparison with those given by other workers, a question arises because the final dilutions in the rapid test are not strictly comparable with those ordinarily given. This is of small consequence, however, provided the method of expressing the results is clearly stated. In the 0.2 c.c. mixtures of the rapid test, the series of serum dilutions 1:10 to 1:2,000 would give a series of final dilutions from 1:20 to 1:4,000. Any particular final dilution in the usual 1 c.c. test would contain five times the actual quantity of serum and antigen contained in the same dilution of the 0.2 c.c. rapid test. Therefore, if based on the actual quantity of serum present in the mixture, the series of final dilutions 1:20 to 1:4,000 of the rapid test would be equivalent to a series 1:100 to 1:20,000 in the usual 1 c.c. test.

Experience with the method—This rapid agglutination technic has been used for *B. pertussis* agglutinations for about a year. Repeated tests have been made with more than 130 recently isolated cultures and with a variety of stock cultures. The method has been used also for testing various antisera for *B. pertussis* agglutinins. The results have been clear-cut and consistent. The data on the serology of recently isolated cultures given in another communication on the cough plate method by Kendrick and Eldering³ are based on this rapid method.

SUMMARY

The rapid agglutination technic has proved far superior to the usual 1 c.c. test for *B. pertussis* agglutination. Most important of the advantages, the tests are completed before any difficulty arises from the nonspecific clumping effect observed in so many *B. pertussis* suspensions. The advantage of the rapidity with which the results are obtained is obvious. In addition, the

agglutination reaction is more clear-cut and the end-points are more easily determined.

VITAL STATISTICS

The Importance of Tuberculosis as a Cause of Death in the Various Age Groups in the Population of Michigan, 1932—In spite of the constantly decreasing tuberculosis mortality observable throughout the United States, this disease is still one of the most important causes of death. Its importance varies in the different age groups and according to sex.

In a study of the ten principal causes of death among persons between the ages of 1 and 60 years in the State of Michigan in 1932, some interesting facts come to light. Excluding the deaths among infants under 1 year of age, tuberculosis as a cause of death appears among the ten principal causes in each age group up to 60 years for both males and females.

In the age group from 1 to 4, tuberculosis is the fourth most important cause of death among females and the fifth most important among males. In the age group 5-9, it appears in fifth place for both males and females with the same number of deaths for each sex.

Starting with the age of 10 years and extending to the age of 45, tuberculosis becomes a much more important cause of death than in the ages under 10. For children between the ages of 10 and 14, tuberculosis among females

takes first place and among males fourth place; then between 15 and 30 years it remains in first place for females and reaches second place for males. In the age period 15-19 years, this disease was responsible for 119 deaths among girls in Michigan in 1932 and for only 58 among boys. For girls, this number of deaths represents slightly more than 28 per cent of all the deaths in this age group; among the boys of this age, the number of tuberculosis deaths represents not quite 11 per cent of the total deaths.

From ages 30 to 35, it is the most important cause of death for both males and females. In the age group 35-40, tuberculosis becomes relatively less important among females than among males, being superseded among females by heart disease and cancer. Among males, however, it is the most important cause of death, being responsible for more than 15 per cent of the total deaths in this age group, as compared with 10.5 per cent among females of this age. In the age group 40-44, it remains at third place among females, and among males it is superseded only by heart disease. The number of tuberculosis deaths among males is more than twice the number among females, and represents 12 per cent of the total

deaths in this age group, while among females it represents only 8 per cent.

As middle age is reached, ages 45 to 49 years, the degenerative diseases become much more important, cancer and heart disease in particular. In this age group, tuberculosis among females has dropped to sixth in importance and among males to fourth. Owing to the higher mortality of males than of females above the age of 40, and to the greater importance of tuberculosis as a cause of death among males in the older age groups, it is reasonable that the number of deaths should be higher; but the fact that they are almost three times as numerous as among females is noteworthy. This discrepancy in the sex ratio of tuberculosis mortality is noticed also in the age group 50-54 years when tuberculosis claims fourth place in the causes of death among males as compared with seventh place among females. In the age group from 55 to 60 years it takes eighth place among females and seventh among males.—*Michigan Public Health*. 21:183-189 (Aug.), 1933; 21:208-212 (Sept.), 1933.

Infant Mortality in New Zealand in 1932—The most remarkable feature of the vital statistics of New Zealand for 1932 is undoubtedly the phenomenal drop in the already very low infant mortality rate. In 1930 this rate stood at 34.48 per 1,000 live births, a figure slightly in excess of that recorded for the previous year. The interrupted downward movement, however, was again resumed in 1931, and continued in 1932, when the rate fell to the unprecedentedly low level of 31.22 per 1,000 live births. This represents a decrease of 79 in the actual number of infants succumbing during the first year of life. During the last 5 years, the reduction in the total infant mortality rate has been due largely to the improvement in the male death rate, which has shown an uninterrupted de-

cline. The female rate, which is much lower than the male, has fluctuated somewhat.

By a more intimate study of the infant mortality statistics, obtained by breaking up the first year of life into smaller divisions, the effect of the influences which have been operating in recent years toward the saving of infant life is made more obvious. The most encouraging aspect of this year's infant mortality rate is the further substantial reduction in the rate for under 1 month. Prior to 1931, the long succession of improvements effected in the total infant mortality rate has been almost entirely due to the diminution in the figures for infants who survive the first month of life. Deaths due to what may be termed prenatal influences generally occur during the first month, and it is this group which has hitherto been least amenable to the efforts made to cope with infant mortality. However, the last 2 years have completely changed the picture, as substantial improvements have taken place in almost every subdivision under 1 month, even down to those occurring during the first day of life.

The decrease in the number of infant deaths registered in 1932, as compared with 1931, has taken place principally in the group "diseases peculiar to early infancy," and as these are mostly of antenatal origin, it would appear that herein lies the explanation of the falling death rate for infants under 1 month of age.

Closely related with the question of infant mortality is the problem of the stillbirth. In New Zealand stillbirths are included in neither births nor deaths. At the same time most of the causes of a child being stillborn are the same as those that would have caused its death within 1 month of birth had it been born alive. In other words, the antenatal factors are responsible largely for the high stillbirth rate and the high

mortality rate of infants under 1 month of age. The stillbirth rate in New Zealand shows a rising tendency, but this is not sufficient to reverse the trend of the declining infant mortality rate when stillbirths are taken into consideration with this latter figure. Indeed, the unusually large decrease in both the total number of infant deaths and of stillbirths for 1932 has had the effect of reducing the combined rate or "total infant-mortality" rate to an unprecedentedly low level. Whereas, however, the rate computed on the usual method indicates a decrease of 29 per cent during the period 1923-1932, the inclusion of stillbirths reduces the improvement to 19 per cent.—*Report on the Vital Statistics of New Zealand for 1932*, pp. X-XI.

Causes of Death in Norway, 1931—According to the *Statistical Year Book for Norway*, the death rate from all causes in Norway increased from 10.5, per 1,000 population, in 1930 to 10.9 in 1931. Similarly the infant mortality rate increased from 45.6 per 1,000 live births to 46.3.

It is interesting to note which causes showed increases and which showed decreases. Of the important epidemic diseases, scarlet fever and malaria were the only two which showed reductions in 1931 over 1930, scarlet fever having decreased from 2.0, per 100,000 population to 1.4 in 1931, and malaria from 0.3 in 1930 to 0.1 in 1931. Against these decreases, typhoid and paratyphoid fever increased from 0.7, per 100,000 population, in 1930 to 1.4 in 1931; measles from 0.4 to 2.0; whooping cough from 1.9 to 2.0; and influenza from 1.7 to 9.1. The great increase in mortality from influenza is reflected in the higher mortality rates from the other respiratory diseases. Acute and chronic bronchitis as well as pneumonia (lobar and unspecified) showed marked increases in 1931 over

1930. The death rate from pneumonia (lobar and unspecified) in 1930 was 38.3, per 100,000 population, and in 1931, 41.8. Tuberculosis, all forms, however, showed a slight decrease having declined from 149.5 in 1930 to 147.5 in 1931.

The increase in mortality from cancer from 127.4 in 1930 to 133.1 in 1931 was considerable, but not entirely unexpected. Similarly the increase in the death rates from cerebral hemorrhage, apoplexy, and softening of the brain from 86.9 to 90.7, per 100,000 population, and the increase in diseases of the heart from 82.5 to 85.3 is in accord with mortality trends in other countries. Slight increases were shown also in ulcers of the stomach and duodenum, and other diseases of the stomach; cirrhosis of the liver; and nephritis; the 1931 rates for these 3 diseases, respectively, were 6.6, 1.8, and 29.5.

Probably the most noteworthy reduction in mortality was in the death rate from external violence which showed a rate of 43.0 in 1930 as compared with 36.2 in 1931. Even suicides showed a slight reduction—from 7.2, per 100,000 population, in 1930 to 6.9 in 1931. Diarrhea and enteritis also declined greatly in 1931, the rate for this year being 6.9 as compared with 9.3 in 1930. Congenital debility and malformations decreased from 32.1 in 1930 to 29.1 in 1931, and total puerperal causes from 5.2 in 1930 to 4.4 in 1931. Slight reductions were shown in the mortality from appendicitis, hernia, and diseases of the female genital organs. *Annuaire Statistique de la Norwege*. 52.18 and 24-25, 1933.

Maternal Mortality in England and Wales, 1932—According to the Registrar General for England and Wales, the annual birth rate for that country has dropped to 15.3 per 1,000 live births in 1932—the fourth consecutive year in which a decrease in the

birth rate has been experienced. A counterbalancing factor is the decline in infant mortality from 66 per 1,000 live births in 1931 to 65 in 1932. The 1932 figure has been improved upon only by that of 60 per 1,000 live births registered in 1930. Total maternal mortality accounted for 5.37 deaths per 1,000 live births in 1932 in comparison with 5.55 in the previous year. However, analysis of the total number of maternal deaths brings to light the fact that, of this number, the puerperal causes alone caused 4.21 deaths per 1,000 live births in 1932—a slight increase over the rate of 4.11 experienced in 1931, while the non-puerperal causes resulted in rates of 1.16 and 1.44 in 1932 and 1931 respectively.

Since stillbirths are now registered as well as notified in England and Wales, figures based on total births (live births and stillbirths) should prove of interest when compared with rates based on live births alone. Total maternal deaths (per 1,000 live and stillbirths) accounted for 5.15 deaths in 1932, 5.32 in 1931, 5.36 in 1930; when based on 1,000 live births alone, child-bearing resulted in corresponding rates of 5.37, 5.55, and 5.59 in 1932, 1931, 1930, respectively. It will be observed that while the rates on a wider basis are lower than those based on live births only, the ratio of mortality in both groups remains practically unchanged.—*An. Rep. Chief Medical Officer, Ministry of Health, Year 1932*, pp. 77-78.

PUBLIC HEALTH ENGINEERING

REPORT OF COMMITTEE ON SCOPE AND POLICY*

THE Committee on Scope and Policy has no formal report to make during the current year. The policy and procedure outlined by this committee and published in the Year Book for 1931-1932 are still regarded as a suitable guide for the Public Health Engineering Section. The committee has been in close touch with the Secretary of the Section and has advised with him with reference to preparation of programs in order that they might conform as nearly as may be to the policies laid down by the Committee on Scope and Policy.

Within the past few years public health engineers have been giving increased attention to the control of respiratory diseases in so far as this can be accomplished through engineering activities. In 1932 there was pre-

sented a report before the Conference of State Sanitary Engineers by the Committee on the Review of Opportunities of Sanitary Engineers in Communicable Disease Control of that organization, in which it was pointed out that there were many opportunities for the application of sanitary engineering principles to the control of communicable diseases transmitted through secretions from the nose and mouth.

This committee, on reviewing the relationship of physical environmental factors to the control of respiratory diseases was impressed with the lack of conclusive proof on many phases of modes of infection and found that there is still much difference of opinion among public health workers. The committee expressed a realization of the complexity of the problem because of the presence of many factors difficult of control, but felt that suitable research might open the way to control of certain of these diseases through public health engi-

* Presented to the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

neering activities. These activities include, among others, air conditioning in buildings in which there may be congregations of people, arrangement of interiors to prevent too close contact, dust control in interiors, and greater municipal cleanliness in public streets and public buildings.

Accordingly the Committee on Scope and Policy recommends that the Committee on Research and Standards of the American Public Health Association be requested to take such measures as

it deems expedient to stimulate research in connection with modes of infection and means of preventing infection in connection with respiratory diseases; also that it be recommended to the Committee on Research and Standards that public health engineers be invited to coöperate in such research.

REPORT OF THE COMMITTEE ON FELLOWSHIP AND MEMBERSHIP OF THE PUBLIC HEALTH ENGINEERING SECTION*

THE Public Health Engineering Section still remains the fifth largest of the Association's ten Sections. On September 1, 1932, the total membership was 449 (125 Fellows and 324 active and associate members). The figures for September 1, 1933, were 118 Fellows and 289 members, a total of 407.

Forty-six new members were secured during the past year and 88 were lost through resignation, lapsing, and death, making the net loss 42.

On September 1, 1933, there were 5 Fellows and 32 members whose current dues remained unpaid, compared with 74 unpaid members and Fellows last September 1.

Due to the necessity for strict economy in the Administrative Office, promotion efforts with engineers were kept to a minimum during the early part of the year. However, 2 months before the Annual Meeting a letter of invitation signed by the Chairman, together with a list of topics to be presented at the Annual Meeting, were sent to over 800 engineers throughout the

United States and Canada. About a dozen new members joined the section up to October 1, as a result of this effort, and returns are still coming in.

The Public Health Engineering Section secured this year the largest number of applications for Fellowship, having 14 out of a total of 62 applications to be acted upon at this meeting by the Governing Council.

Next year the committee plans to concentrate on the selected list of prospects it has prepared, and hopes to report a substantial increase in section membership by the time of the 1934 annual meeting. In this connection we should like to urge every member and Fellow of the section to assist wherever possible in strengthening his section by securing new members.

INDUSTRIAL HYGIENE

Annual Report, The South African Institute for Medical Research, Year Ended December 31, 1932—We are making several excerpts from this 71-page Report, as follows:

DEPARTMENT OF INDUSTRIAL HYGIENE

Animal experiments with dust—While there is no difficulty in setting up lesions in rabbits, guinea pigs, and rats that have been exposed to dust, the condition produced is not a true dust-phthisis as met with in the human subject, owing, presumably, to certain differences in the structure of their lungs. Monkeys are now being used for this experimental work, and the dusts under investigation are blown direct into the tracheae. To start with, there was some difficulty in arriving at a suitable anesthetic, and, acting upon the suggestion of J. B. Quinlan, of Onderstepoort Veterinary Research Laboratories, a trial was made of Eukodal, and it has proved quite satisfactory for vervet monkeys. An injection of 0.01 gm. is given by the subcutaneous route, and within less than 5 minutes a tube can be introduced through the vocal cords. The animal does not lose consciousness, it is simply indifferent. Recovery is rapid, and there is no coughing. This investigation is being undertaken with three objects in view: (1) To produce a true silicosis. (2) To compare the behavior of other dusts with the behavior of SiO_2 and to learn whether, in the presence of SiO_2 , dusts become harmful which are harmless in its absence. (3) To follow the path of dust through the lungs. Is the different behavior of certain dusts related to a difference in their path of entry to the alveoli?

Dust estimation: An inquiry suggested by the International Silicosis Conference, Johannesburg, 1930—The Department of Industrial Hygiene is also directly interested in a number of problems and investigations through its collaboration with the Mine Air Committee of the Chamber of Mines and with the Miners' Phthisis Prevention Committee. Dr. Mavrogordato is the institute's representative on both these bodies, and has been actively engaged in the work described below.

The different countries and centers who have portions of their population employed in "dusty-trades" use various methods for the estimation of the concentration of air-borne

dust. These methods yield results which are not comparable with one another, and the International Silicosis Conference that met at Johannesburg in 1930 urged the need for a standard method. With a standard method the results secured by different procedures for dust-control could be compared. Information of this sort was not available, and the Conference felt the need for it.

The methods in use on the Witwatersrand are the konimeter and the sugar-tube. The untreated slides provided by the konimeter do not distinguish between phthisis-producing and other dusts, while the volume of air that can be sampled by the sugar-tube is limited by the melting of the sugar in moist atmospheres. With low concentrations of air-borne dust, samples of small volume are unsatisfactory. The Mine Air Committee of the Chamber of Mines has undertaken this investigation in their Dust-sampling Laboratory. Methods have been devised for the elimination of dust other than phthisis-producing dust from konimeter slides. The extent to which these methods may influence the apparent concentration of phthisis-producing dust is still under consideration.

With regard to the use of the sugar-tube for gravimetric-sampling, the practice of using cotton-wool as the filter had been discarded on the Witwatersrand in favor of sugar, because cotton-wool did not yield a constant ash-weight. A cotton-wool yielding a constant ash-weight is now available. Cotton-wool is an even more efficient catcher of dust than is sugar, and has the advantage of permitting large samples of air to be dealt with. One can sample up to 1,000 cu. ft. of air as compared with the 12 cu. ft. dealt with under the routine procedure. The small samples were secured by a hand-pump, and took some 10 minutes to collect; the large samples take several hours, and the air is drawn by a Bunsen injector. The total catch from the 1,000 ft. samples averages about 30 mg., as compared with the 0.35 mg. averaged by the 12 cu. ft. samples. The crude catch is treated as were the samples secured by the sugar-tube. It is first ignited to remove the cotton-wool and all organic matter, and then washed in boiling water to remove the water-soluble particles. Before the final drying and weighing, the dust is washed through a sieve of 350 mesh to the inch to remove gross particles.

The dust, after weighing, can be taken up in a measured volume of water and counted in a "deep-cell" as used with instruments of the hydro-konimeter type, thus combining gravimetric and enumeration returns from the same sample. The deep-cell affords the opportunity of determining the size-frequency of the particles in our air-borne dust underground. Some 70 per cent by number of these particles are found to be of the order of 2 microns or less. It is of interest to note that these large samples compare very well as to concentration with the routine small samples. One thousand cu. ft. is about 30 cu. m., while the routine samples dealt with a third of a cu. m. One was unhappy with the third of a cu. m. samples, because the ash of the filter-paper usually exceeded in weight the total amount of dust actually caught. It has turned out that both large and small samples give an average concentration of air-borne dust amounting to about 1 mg. per cu. m.

In connection with this inquiry, the Committee on Mine Air is making trial of the Greenberg-Smith Impinger, an apparatus of the hydro-konimeter type, which admits of gravimetric and enumeration returns being carried out on the same sample. The gravimetric returns compare to a satisfactory extent with samples taken at the same time with the sugar-tube or cotton-wool. By this method slightly less dust is caught per unit volume of air than is caught by the sugar or cotton-wool. It has the advantage of avoiding the necessity for correcting on account of the dust in the sugar or the cotton-wool ash. The dust enumeration is at present performed in the deep-cell, but more experience will be required before it will be possible to correlate enumeration returns with deep-cell counting with enumeration returns by ordinary konimetry.

The different methods in use here and elsewhere for securing gravimetric returns yield results varying within quite narrow limits. This inspires confidence. On the other hand, different methods of securing enumeration returns do not yield results which correspond with any pretense to approximation. All that can be said is that the results secured by the same method can be compared with each other. While there is no correspondence between the "counts" yielded by the different methods, there is very tolerable correspondence between the size-frequency of particles caught by the different methods. It is possible that the association of a gravimetric return with a size-frequency return will be the best way for the different countries to secure results comparable with one another. The objection

to size-frequency returns for ordinary routine work is that this procedure takes up too much time. It has never been suggested that all countries should adopt a standard method for all purposes; it was suggested that each country interested should return a limited number of surveys by the standard method.

Studies Underground—Various mines have been experimenting with encouraging results on methods of filtering off the air-borne dust by means of screens placed in the path of the air-current. The staffs of the Miners' Phthisis Prevention Committee appointed by the government and of the Committee on Mine Air of the Chamber of Mines have dealt with this work.

A certain amount of air-borne dust is unavoidable in mining, and a certain amount of water must be used to deal with it. Dust-surveys are undertaken with a view to tracing sources of avoidable dust, and during the past year, humidity surveys have been undertaken by the Committee on Mine Air with a view to tracing sources of unnecessary water. With the deep hot mines of the Witwatersrand it is becoming increasingly important to learn whether the relative humidity of the air can be reduced to a useful extent without prejudicing the position with regard to air-borne dust. This problem is a difficult one. Most of the shafts are timbered and have to be kept wet for various reasons; the air is nearly saturated by the time that it reaches the bottom of a wet downcast. If this saturated air heats up on its way to the working places there will be some depression of the wet-bulb unless more water is added, but the fall in relative humidity thus secured is hardly of a useful degree. It is no use scheming to control the water at the working places if the air reaches them almost saturated at their own temperature. The initial difficulty is to dry up these timbered shafts to an extent that will admit of air reaching the bottom at a relative humidity of about 80 per cent. Something is to be gained by doing away with what a golfer might call casual water arising from drippers and such like sources. This can be done if it is worth while. There remains the necessary wetting of the timbers to avoid distortion and fire risks. At present inquiry is directed toward finding means for so treating the water that evaporation is slowed down and safety secured with the use of smaller quantities and less frequent application.

PATHOLOGICAL DEPARTMENT

Cases of Interest—During the year a gas-sing accident occurred on one of the mines. This was subsequently stated to be due to

sulphuretted hydrogen, derived apparently from stagnant water which had been tapped in the mine. Several fatalities occurred, some within 24 hours and one 3 weeks later.

At the autopsies performed on those who died within 24 hours of exposure to the gas, the chief lesions found were as follows: An acute edema glottidis, an acute pulmonary edema with brownish colored fluid in the bronchi and trachea, and an acute gastritis; in the stomach gas was present in considerable quantities, which had the odor of sulphuretted hydrogen; this was not noted in the intestines. The blood was dark and fluid, but not chocolate colored. No evidence of sulphemoglobin was found on spectroscopic examination.

The man who died 3 weeks after the exposure expired very suddenly. During the 3 weeks his chief complaint was of some gastric disturbance; apparently, too, there was some vagal irritation, and his pulse was irregular, at times being slow, but there appeared to be little serious damage done, and he left hospital only to drop down dead suddenly.

The cause of his sudden death was not determined at autopsy nor even after histological examination of brain, lungs, liver, kidneys, heart, and stomach. The only lesion found apart from intense congestion of the organs was a gross subacute gastritis, the result of his poisoning by sulphuretted hydrogen.

It is suggested that his death was due to involvement of the vagus nerve in neuritis, initiated by the poisoning and continued by the gastritis.

Lungs Examined for Silicosis and for Tuberculosis—These examinations carried out on behalf of the Miners' Phthisis Medical Bureau, whose pathological work is carried out by the institute, numbered 491.

European cases accounted for 260, Eurafrian for 4 and Natives for 227, of which groups, 164, 1 and 45 respectively, showed no evidence of silicosis nor of tuberculosis.

Tuberculosis, uncomplicated by silicosis, was present in 11 European, 1 Eurafrian and 133 Native cases.

Silicosis, uncomplicated by tuberculosis, was present in 45 European and 11 Native cases.

Silicosis, complicated by tuberculosis, was present in 40 European, 2 Eurafrian and 38 Native cases.

One case of primary lung carcinoma was noted among the European cases.

Gangrene of the lung, associated with enlarged tuberculo-silicotic gland eroding the bronchi, was noted in 15 Native cases.

Additional Investigations (Pathological Department)—During the present year two

separate investigations are being carried out, both dealing with silicosis, but on different lines.

The first deals with the pathology of the lungs of a male European who has been engaged in work connected with the Johannesburg sewerage scheme.

Some months ago Dr. Pringle, of the Springkell Sanatorium, performed an autopsy on the body of one of these workers, and, being struck with the unusual nature of the lesions in the lungs, forwarded them to the institute for further and complete examination. The pathological change was found to be an unusual type of gross, unpigmented silicosis.

Upon inquiry it was found that the danger had not been apprehended and that conditions under which these men worked were extremely bad. They worked either in unventilated tunnels or in deep open trenches, drilling with dry drills, and no attempt whatever was made to keep down the dust. The result was that the men were inhaling enormous amounts of dangerous dust. In some places, according to reliable analysis, the dust contains as much as 97 per cent free silica.

According to our observations so far completed, and taking the history into account, the pathological process set up is of a very advanced type, and is developed in a very short period of time.

In many respects the silicotic lesions are different from those which occur in the Rand miner, and, further, they approximate more nearly to the lesions met with in the experimentally dusted animals.

Up to the present it has been difficult to explain why the changes in the lungs of animals so treated do not correspond more closely to those of the natural disease as met with in miners. It is hoped, when this investigation is completed, that several problems relating to silicosis will be cleared up.

The second piece of work is a reconstruction model, magnified by 20 diameters, of the silicotic process, and shows how it involves the important structures in the region of the entrance to a primary unit of the lung.

With the help of J. de Bruyne, a technic has been evolved which has given very satisfactory results.

Since the model has been completed, we have learned that a similar technic has been employed by Millar in America, but our work has been done quite independently.

In our method a large series of serial sections, each 20 micro mm. in thickness, was cut and the required part in each section was photographed ($\times 20$) directly upon bromide paper. Each completed negative photograph

thus prepared was then superimposed upon cardboard (0.4 mm. in thickness), and the image of the silicotic lesion with the adjacent structures in relationship with it was punched out. The punched-out objects were now accurately superimposed and pasted together, the final result being an exact replica, on a much enlarged scale, of the lesion and its related anatomical structures.

The model has been reconstructed strictly to scale in three dimensions.

The reconstructed model shows the distribution of the pigment and the silicotic nodule; it shows that fibrosis and pigmentation occur to a much greater extent than can be realized by ordinary histological examination; it confirms the view which we have long held that the silicotic lesion develops in certain definite anatomical situations in the lung substance; and it has given us reason to believe that the silicotic process causes gradual occlusion of the terminal air passages.

In this reconstruction, which is of an early silicotic nodule, the narrowing of certain parts of the terminal air passages is definitely shown, but a second model will require to be made of a nodule in a more advanced state to prove that actual occlusion finally occurs.

If the occlusion of terminal passages is definitely proved, it means collapse of the affected primary unit and will explain how the massive areas of silicosis are formed.—

Obtainable through the British Library of Information, 270 Madison Avenue, New York.
E. R. H.

Ventilation and the Need for New Standards—The author feels that the contamination of the air by microbes has been unnecessarily submerged in present day thinking about ventilation, and he therefore suggests that dust counts or bacteria counts should be favored as a sounder basis for estimating the purity or otherwise of the air. The conditions which make for comfort should be clearly distinguished, when necessary, from those favoring health. Several pages of valuable discussion follow.—J. S. Owens, *J. Roy. San Inst.*, 53, 11:623-635 (May), 1933. E. R. H.

Law of March 16, 1933, on the Daily Hours in Industrial Establishments

THE law of March 16, 1933, prescribes a maximum working day of 8 hours and a maximum week of 48 hours for persons employed in industrial establishments of any kind, whether public or private, except in the postal, telephone and telegraph services, inland navigation by water and air, the fishing industry, and establishments in which only the members of the same family are employed. The law does not apply to persons occupying executive or supervisory positions or to home workers.

Longer hours may be permitted regularly in occupations, among others, with

intermittent or simple processes, in those requiring little attention, in continuous industries, and in special preparatory or supplementary work that must be performed outside regular working hours.

Overtime work is permitted in case of emergency, when work must be done to machines or other apparatus, and to take care of extra orders, but shall not exceed 12 hours a week for a definite period.

The law is to be enforced by inspectors. Penalties are provided for violations.—*Rassegna della Previdenza Sociale*, Rome, June, 1933.

FOOD AND NUTRITION

The Escherichia - Aerobacter Group of Bacteria in Dairy Products—The Escherichia - Aerobacter group comprises one of the important groups of bacteria in dairy products. Milk, even under careful conditions of production practically always contains some of these organisms. The fact that the Escherichia type generally represents organisms coming from the intestinal tract of man and animals and the Aerobacter type organisms from soils and grains makes a distinction between the two types useful. The growth of Escherichia-Aerobacter organisms in dairy products is undesirable, for in addition to forming acid and gas from lactose they produce undesirable flavors and aromas. Some of the defects which have been reported as due to this group of organisms are ropiness in milk and cream and gassy fermentations in cottage cheese, cheddar cheese, milk, and sweetened condensed milk.

Two methods were employed for isolating organisms of Escherichia-Aerobacter type from dairy products. In the first method gentian violet lactose bile broth was used as an enrichment medium. Durham fermentation tubes were isolated in duplicate with dairy products diluted in multiples of 10. Gas formation was recorded after 48 hours' incubation at 37° C. Eosin methylene blue agar plates were streaked from tubes of the highest and lowest dilutions showing gas after 24 hours' incubation. Typical colonies of the Escherichia-Aerobacter types of organisms were secured from these plates. The approximate number of Escherichia-Aerobacter organisms per c.c. was determined from the fermentation tubes, by the dilution method.

A direct plating method was used for the isolation of cultures, whenever possible. Milk or cream was plated directly with eosin methylene blue agar in dilutions of 1:10 or higher. Surface colonies were secured by placing the inoculum on the surface of the pre-dried E.M.B. agar plates and then distributing it uniformly with a glass rod bent at right angle. When all of the inoculum was absorbed upon the surface of the agar the plates were inverted and incubated for 48 hours at 37° C. The number of colonies of each type was then recorded and a representative colony of each type isolated for pure culture study.

Tests employed for identification of cultures were the methyl red and Voges-Proskauer tests, utilization of citrate as the sole source of carbon, motility, liquefaction of gelatin, reduction of nitrates, formation of indol, action on litmus milk, and fermentation of glucose, lactose, sucrose, dulcitol, and salicin, with acid and gas production.

In this study, 204 cultures belonging to the Escherichia-Aerobacter group were identified on a species basis according to the scheme of classification used in Bergey's Manual. These cultures were isolated from raw milk, pasteurized milk, raw cream, ice cream, ropy milk and cream, and from defective butter. The genus Escherichia comprised 63 per cent of the cultures from the raw milk; 57 per cent from pasteurized milk; 33 per cent from raw cream, and 31 per cent from ice cream. The genus Aerobacter comprised 26 per cent of the cultures from raw milk; 10 per cent from pasteurized milk; 57 per cent from raw cream; 56 per cent from ice cream; 100 per cent from ropy milk and cream; and 88 per cent from defective butter.

The intermediate group comprised 11 per cent of the cultures from raw milk; 33 per cent from pasteurized milk; 10 per cent from raw cream; 13 per cent from ice cream, and 12 per cent from defective butter.

The most common species in the dairy products studied were *E. coli* in the raw milk, *E. pseudocoloides* in pasteurized milk; *A. cloacae* in raw cream, ropy milk and cream, and defective butter.—M. W. Yale, *J. Dairy Sci.* 16:481 (Sept.), 1933.

Vitamin Tests on California and Asiatic Dates—Three varieties of dates were included in this study—Asiatic Hallawis, California grown Hallawis and California grown Deglet Noor. Three samples of each variety were tested. Asiatic Hallawi dates—pasteurized, unpasteurized and locally purchased pasteurized (Dromedary dates)—were tested for vitamin A. The pasteurized sample was also tested for vitamin C, and both the pasteurized and unpasteurized samples were tested for vitamin D. The vitamin A content was found to be nearly identical in the three samples, a small decrease being noted as a result of pasteurization or marketing conditions. No vitamin C was found in the amounts which the animals would eat.

Three samples of California grown Hallawi dates—all tree ripened, one fumigated with carbon disulphide, and one fumigated and commercially washed, were tested for vitamins A and D. The vitamin A content in the tree ripened and fumigated samples was found to be nearly the same as that of the imported Hallawis, but was much less in the washed sample. Slight vitamin D values were shown.

Three samples of the California grown Deglet Noor dates were tested for vitamins A and D. These were tree ripened, tree ripened and fumigated, and artificially matured. The vitamin A

content was found to be somewhat larger in the artificially matured sample of this date than in the Hallawis. No deterioration was noted as a result of either the maturation or fumigation processes used. Only the tree ripened sample was tested for vitamin D and only a slight antirachitic value was found.—Agnes Fay Morgan, *J. Home Econ.* 25:603 (Aug.-Sept.), 1933.

The Pellagra-Preventive Value of Green Cabbage, Collards, Mustard Greens, and Kale—Previous experiments have been reported (abstract, *A.J.P.H.* 22:93 (Jan.), 1932), on canned spinach, turnip greens, green beans and mature onions. It has been necessary to continue to employ the canned product in testing green vegetables for the reason that usually they are not available in the fresh state for a sufficient length of time to permit adequate feeding experiments. However, it has been shown that the pellagra-preventive factor is not appreciably affected by the heat incident to canning.

The basic diet in the case of the tests on cabbage and collards consisted of corn meal, cowpeas, flour, lard, baker's bread, canned tomato juice, cod liver oil, calcium carbonate, sirup iodide of iron, and dilute hydrochloric acid. This diet was supplemented daily with 482 gm., including the can liquor, of canned green cabbage in one case and canned collards in another. The test period in each case was 1 year.

While cabbage was found to contain the pellagra-preventive factor, it cannot be said to protect completely even in the generous amounts given, since 1 of 15 colored females on this diet developed pellagra in 7 months. However, in view of its adaptability, cheapness and seasonal availability, green cabbage may be considered a very practicable contributory source of pellagra prevention.

Canned collards were found to be a satisfactory pellagra-preventive supplement, since in a group of 16 colored females, 13 of whom continued the diet for 1 year, none developed pellagra.

In the test on mustard greens and kale, the basic diet was the same as in the case of cabbage and collards, except that baker's bread was omitted. The daily allowance was 533 gm. in the case of canned mustard greens, and 534 gm. in the case of kale. While mustard greens contain the pellagra-preventive factor, they cannot be regarded as a rich source of it. Of 14 white females on the kale-supplemented diet, none developed any symptoms of pellagra.—G. A. Wheeler and D. J. Hunt, *Pub. Health Rep.* 48:754 (June 30), 1933.

Effect of Carbon Dioxide and Sodium Benzoate on Vitamin C Content of Orange Juice—The processes used in this experiment were:

1. Freezing and storage in the frozen condition
2. Addition of not more than 0.1 per cent sodium benzoate to canned or bottled juice
3. Carbonation—that is, treatment with carbon dioxide gas under pressure previous to bottling and pasteurization

Two samples each of California valencia and navel orange juices which had been kept in frozen storage for 8 to 18 months showed antiscorbutic value fully equivalent to that of freshly extracted orange juice. A daily dose of 2 c.c. afforded complete protection in all cases.

A sweetened orange juice, similar to

preparations on the market, prepared in two forms—with and without 0.1 per cent sodium benzoate—was tested for antiscorbutic activity. This preparation appears to have at least two-thirds the vitamin C value of whole fresh orange juice, the diminution being due no doubt to the dilution with sugar. Sodium benzoate appeared to have no deleterious effect upon the vitamin C.

To study the effect of carbon dioxide upon the preservation of vitamin C, 5 samples of the orange juice products were prepared as follows:

1. Slightly sweetened valencia orange juice, diluted with water containing 0.1 per cent dissolved carbon dioxide
2. The sweetened juice, diluted with water but containing no carbon dioxide
3. Frozen, untreated, whole valencia orange juice
4. The frozen juice, packed in bottles, but pasteurized for 25 minutes at 63° C. and treated with carbon dioxide at a pressure of 2.5 kg.
5. The frozen orange juice, pasteurized as above, but without carbon dioxide treatment

Nearly complete protection from scurvy was provided when 8 or 9 c.c. daily doses of sample 1 were given. Sample No. 4 retained the full vitamin C value of the fruit juice which it contains, 6 or 7 c.c. being approximately equivalent to 1 c.c. of freshly extracted orange juice. It is not surprising that carbon dioxide treatment should have this protective effect when the sensitiveness of vitamin C to oxidation is recalled.—Agnes Fay Morgan, Catharine I. Langston and Anna Field, *J. Indust. & Eng. Chem.* 25:1174 (Oct.), 1933.

CHILD HYGIENE

A NEW RAMIFICATION OF THE DENTAL PROBLEM

JOHN OPPIE MCCALL, D.D.S.

Director, The Murry and Leonie Guggenheim Dental Clinic, New York, N. Y.

IT is no longer news that dental decay is one of the most, if not the most, prevalent human diseases and that the infections and functional disabilities which follow uncared-for dental cavities are a potent source of ill health. Medical men as well as dentists are concerned over the undermining of community health which is recognized as being progressively on the increase from this cause. For this reason much research work is being carried on in both medical and dental institutions in the effort to learn the ultimate causes of dental caries and the means for its prevention.

Pending the discovery of the solution to those problems, increasing efforts are being made to stem the growing tide of dental disease through various community activities directed toward the amelioration of the situation. These efforts follow two differing but related courses. One is the dissemination of such knowledge as is now available regarding means of preventing dental caries. This is carried on through the usual educational channels, with special emphasis on the application of preventive measures in childhood. The public school is a natural and effective medium through which these educational messages may reach the people. The other course is the provision of such operative treatment, both the filling of teeth and their prophylactic cleansing, as is feasible. Here, too, the school has been looked upon as constituting the proper *locale* for the carrying on of this activity.

This latter belief has been reached

partly by following the line of least resistance, and also the line indicated by the trend of professional concept as to the best means of attacking the problem of existing dental disease. That is to say, the school is the natural gathering place of virtually all the children in any community above the age of 5, hence it offers an opportunity to conduct dental examinations and give dental treatment on a community-wide basis. Also it has so far been the belief of the dental profession, as it has progressively studied the problem of coping with dental disease on a broad basis, that a program for giving dental care to be begun at the average age for entering school, that is, 6 years, would satisfy such criteria as might be set up for such a project.

It should be explained that the thought of giving dental care as a community project first attained a prominent place in dentists' minds about 30 years ago and at that time dentists began making voluntary surveys of various schools, to determine the dental conditions obtaining among school children. One of the outstanding facts brought out in these early surveys was the prevalence of serious damage suffered by the so-called 6-year molar. Since impairment of masticating efficiency and serious malformations of the dental arches were found to be due to early loss of this tooth, it soon became the rallying point of those who were interested in dentistry for children, and its preservation became the immediate goal of the pioneers in this movement.

The coincidence of 6-year molar eruption and school entrance, plus the convenience of established machinery for supplying the necessary contacts, served to make children's dentistry a school function.

At that time there was no appreciation on the part of either dentists or physicians of the influence of dental infection on the general health, hence little attention was paid to decay and abscess in the deciduous teeth. As the years have gone by, dentists have begun to realize the seriousness of focal infection resulting from decayed and abscessed teeth, even in the deciduous dentition. They have also found that much irregularity in the position of the permanent teeth, including the first permanent molar itself, is traceable to decay and loss of the deciduous teeth, especially the deciduous molars, and also that the incidence of caries in these teeth is showing an alarming increase. With the realization of these things comes the necessity for recasting the program of dentistry for children. While the first permanent molar still deserves serious consideration, it can no longer stand as the first point of attack in the community dental program. It is imperative that plans be developed for giving comprehensive attention to the deciduous teeth and to provide this care before the child enters the public school system.

In addition to the health consideration mentioned, the matter of economy dictates this move. It is less expensive to fill cavities while they are small, and there is good reason to believe that fewer cavities will form in a mouth receiving periodic care. With preservation of the deciduous teeth there will be less irregularity of the permanent teeth, and this means a lower cost for the care of these teeth throughout life. The argument for beginning dental care early in the preschool period is given weight by the following figures gathered

at The Murry and Leonie Guggenheim Dental Clinic in New York City.

This clinic began operation in its present building September 14, 1931. Up to October 7, 1933, 10,147 children have been received there as patients. The usual age of admission for new patients is from 2 to 10 years. There have been a few admissions over this age limit. Since all children in the clinic district who are financially eligible are received, the findings may be accepted as constituting a cross-section of the dental condition of the preschool and school population of Greater New York. Of these children only 230 were free from caries; this means that 97.7 per cent had one or more cavities of decay.

While these figures are higher than those usually given as the result of school surveys, they will not occasion surprise, at least to dentists. What may cause both surprise and concern to dentists and to all others interested in health matters is the way in which the percentages mount, beginning at an age well below that of school entrance.

In the absence of an organized means for registering all preschool children, dependence is placed on day nurseries and similar organizations and on letters to parents known to have children below school age. Figures for this group are not, therefore, reliable cross-section figures. When, however, we relate the percentage of caries shown below to the total percentage for all ages up to 10, given above, we are justified in believing that findings for the entire preschool population would coincide rather closely with those given. They indicate not only an early beginning but a rapid increase, in extent, of caries in most preschool children. Incidentally comparison of the total caries incidence with the figures for preschool children indicates that the 2.3 per cent average for freedom from caries is derived almost entirely through the inclusion of pre-

school figures in the total tabulation. In other words, caries is found to be practically universal among children of school age in New York City.

The following figures for preschool children are tabulated on yearly levels.

With increase in incidence of caries and number of cavities goes, naturally enough, increase in their size and probability of pulp involvement with its sequel of dental abscess. An alarming number of children entering kindergarten are found to have many unsavable teeth and to be in need of time consuming operations on those that are savable. It seems fairly obvious, then, that both health and economic considerations demand the setting up of machinery for the registration of all preschool children and the institution of

CARIES IN PRESCHOOL CHILDREN

systematic dental care for them. The age of 2 would seem to be the logical age at which to start this program.

PUBLIC HEALTH NURSING*

PUBLIC HEALTH NURSING AT THE INDIANAPOLIS A.P.H.A. MEETING

First Joint Session

Monday morning, October 9, the Public Health Nursing Section had a joint session with the Child Hygiene Section and the American Association of School Physicians. The comparatively small maximum attendance of 150 at this session was no index of the significance or interest of the ideas expressed in the papers. Although one physician insisted that school teachers should teach and if they could not, they should be fired, and that physicians connected with school systems should practise medicine, not teaching, the consensus of opinion as indicated in the discussions seemed to be that teachers need to be better trained to

teach both in their own special fields and in the field of health education—and school physicians and nurses could be more effective if they were more skilled in the fundamental principles of education.

Business Luncheon (Monday noon)

Elsbeth Vaughan, R.N., St. Louis, Chairman of the Public Health Nursing Section, presided.

The section voted to have the following new committees appointed.

1. On Historical Review and Re-statement of Objectives of the Public Health Nursing Section.

2. On Membership and Stimulation of Fellowships in the Public Health Nursing Section.

3. On Study of Nursing Services in State Health Departments in Coöperation with the N.O.P.H.N.

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

The following nursing Section Council and Committee representatives were elected:

Chairman—Pearl McIvor, Washington, D. C.
Vice-Chairman—Naomi Deutsch, San Francisco, Calif.

Secretary—Eva F. MacDougall, Indianapolis, Ind.

New Councillor—Ann Heisler, St. Louis, Mo. (Term expires in 1938).

Nurse Member on A.P.H.A. Nominating Committee—Katharine Tucker, New York.

Nurse Member on A.P.H.A. Membership and Fellowship Committee—Alma Haupt, New York.

Lillian A. Hudson of New York is section representative on the sub-committee 'on Training and Personnel.

Section Councillors and years their terms expire are:

| | |
|----------------------------------|------|
| Ruth Houlton, Minneapolis, Minn. | 1937 |
| Amelia Grant, New York | 1936 |
| Elizabeth Stringer, New York | 1935 |
| Marguerite Wales, New York | 1934 |

The Tuesday Afternoon Nursing Section Session

This drew an attendance of 260. Watch the *Journal* for Miss Wales' paper on "The Contribution of Public Health Nursing to Communicable Disease Control" which was discussed from the floor by Dr. Louis I. Dublin and Haven Emerson, M.D., of New York. The papers written by Agnes Talcott and Marion Randall were eagerly listened to, and every nurse sat on the edge of her chair drinking in what Alma Haupt had to say about "How to Fit Public Health Nursing into a Budget."

There were about a dozen men in the audience. We hope most of them were health officers. Dr. Peter of Cincinnati and Dr. Decker of Los Angeles were recognized among them.

The Wednesday Morning Nursing Section Meeting

"Team Play. Between Public Health Nurses and The Medical Profession" read by Dr. W. W. Bauer of the American Medical Association proved very

interesting, and the discussion of it by Louise Nichol, R.N., of the Illinois State Health Department was just as good. There was good natured disagreement between the two on some points, and a spirited discussion from the floor by Miss St. Clair, Miss Tucker, Mrs. C.-E. A. Winslow, and Miss Havey.

The second part of the morning program on the "Use of Laymen in Official Public Health Nursing Services" was discussed by Dr. Dowling of Alabama, Mrs. Blackstone of Wisconsin and Mrs. Trawick of Tennessee, the latter two emphasizing the rural point of view, and interspersing their papers with apt and witty stories. An interesting outcome of this last phase of the program was the eagerness with which the three speakers got together to compare notes after the meeting.

The Thursday Afternoon Joint Session With the Indiana State Nurses' Association and the State League of Nursing Education

The attendance was 360, the room was packed to hear Dr. John Sundwall of Michigan speak on "Health a Factor in Quality Nursing" and Mary Beard, R.N., of New York on "The Undergraduate Curriculum a Factor in Quality Nursing."

Marion Howell of Cleveland was unable to come to the meeting to discuss Miss Beard's paper, and Shirley Titus, Dean of Vanderbilt University School of Nursing, Tennessee, took her place. She put her discussion in the form of the following questions:

1. Is Nursing that is worthwhile quality nursing?
2. What place does health occupy today in social well-being?
3. Is the curriculum that emphasizes disease rather than health an adequate one?
4. Is a nursing school to prepare nurses for specialties?

5. Is public health nursing a specialty?

6. Can a nurse be effectively prepared for public health nursing if public health education has to be superimposed on hospital technics and ethics?

7. What to do about a curriculum which is a product of utility? Should it be arranged according to function?

An Extra on the Program

One of the most stimulating and helpful nursing sessions at the Indianapolis meeting was the luncheon meeting informally arranged by the N.O.P.H.N. for public health nursing executives on Wednesday at the Lincoln Hotel. Fifty nurses sat down together and when each introduced herself at the request of Miss Tucker one had to marvel at the great number of states and types of services that were represented by public health nurses who felt the Annual Meeting of the American Public Health Association was valuable enough to justify them in paying their own expenses to attend it, as many of them did. Predominating in the group were state supervising nurses, directors of visiting nurse associations, directors of official city health department nursing services, public health nursing course directors, etc. It was an elite group.

After the luncheon the group re-

mained and for 2 hours, under Miss Tucker's leadership, discussed Rules and Regulations No. 7 of the Federal Emergency Relief Administration as they applied to public health nursing.

The proposed schedule for the N.O.P.H.N. sessions and joint sessions for the Biennial Convention to be held in Washington, D. C., in April was furnished each nurse and there was a general discussion about it.

More Personal

One distinguished Fellow of the Public Health Nursing Section of the A.P.H.A. who attended the meeting was Miss Elizabeth Smellie of Ottawa, Canada, who is Superintendent of the Victorian Order of Nurses for Canada and Honorary Consultant in Public Health Nursing to the Ontario Health Department.

Miss Smellie and Miss Lillian A. Hudson of the Department of Nursing Education, Teachers College, Columbia University, spent an evening at the home of Dr. and Mrs. Willis D. Gatch where the main topic of conversation was public health nursing. Dr. Gatch is Dean of the Indiana University Medical School and Mrs. Gatch, Miss Smellie, and Miss Hudson are all alumnae of Johns Hopkins Hospital Nursing School. EVA F. MACDOUGALL

EDUCATION AND PUBLICITY*

Indianapolis in Retrospect—Our best attended session and one which held the audience to the end, was the "panel" meeting with the subject, "Is there a common objective in public education around which all health organizations can rally?" Dr. Winslow as chairman very skilfully held the group of panel members to a practical discussion of the question. Each member proposed an objective and through discussion, there were eliminated: the importance of periodic health examination; a campaign against quackery; the importance of adequate medical care for everyone; the value of personal health. The consensus of opinion, with the audience agreeing, was that all health agencies should join this year in stressing the importance of maintaining adequate public health services. A continuation of this discussion by local health councils might be well worth while. For further information on how to go about it write to Dr. H. E. Kleinschmidt who arranged this panel session.

The two papers which we believe will be of exceptional value to workers in health education are: Mary P. Connolly's story of how adult groups are brought together for health education in Detroit, and Dr. M. O. Bousfield's account of how best to reach the negro community with health education. These will be made available to *Journal* readers.

The Health Education Institute under Dr. Galdston's leadership was again a successful feature of the Conference program and it was voted at our business session to ask for its continuance another year.

With the prospect of a meeting next fall on the Pacific coast, there is likely to be an entirely new group for attendance at an institute.
M. S. R.

The "Makings" for Magazine Articles—Data from the field are necessary for the writing of articles on public health topics. There is little doubt that many more articles would be published if varied information, interesting and valuable, could be supplied to writers.

The material is to be found in annual reports, research reports and studies of many types, clinic records, case stories, etc. A line or a paragraph, an incident or other example even, may provide an article angle or theme about which material may be assembled by the writer. Whatever will help to define or to explain a public health problem or situation will be useful.

Health councils and all other local and state groups of health workers are invited to discuss how to bring this opportunity to the attention of health agencies. Likewise every individual health worker is invited to collaborate in this effort for the common good. State departments and state associations could help in explaining the idea to local agencies.

Please ask the editor of this department at 130 East 22d St., New York City, for full information.

In Place of a Speech—There are a lot of ways to use spoken words in presenting ideas and information, without making a speech. A dozen or more examples will be mailed to you, if you will look them over, promising that if you discover an omission you will

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

briefly describe the omitted form. Please drop a postal card to the editor of this department.

Objectives in Cancer Education—Twelve pages on "Cancer Education in Massachusetts," by Dr. Mary R. Lakeman, form a valuable contribution to the study of resultful popular health education. These 12 pages constitute a chapter in *Cancer and Other Chronic Diseases in Massachusetts*, by Dr. G. H. Bigelow and Dr. Herbert L. Lombard. Houghton Mifflin Co., Boston. 1933. Says Dr. Lakeman:

The educational program as outlined presented these main objectives:

1. To give people of adult years sound information about cancer, so that they may act with intelligence when occasion demands.
2. To give wide publicity to the fact of the curability of early cancer.
3. To keep the people living in the neighborhood of each clinic informed of the day, hour, and place of the clinic.

It was considered to be of special importance that everyone become familiar with the cardinal signs which should arouse a suspicion of cancer; namely, the lump anywhere in the body, the unhealed sore, the unaccustomed discharge from a body orifice. Hence, during the first two or three years of the Massachusetts program the chief emphasis in all publicity given out was laid on these signs.

A definite effort is being made to change the attitude of mind toward cancer. Among older women, we meet on all sides an unwillingness to face the problem, a sense of horror which forces people to turn away when the word is spoken. This attitude seems to exist in far less degree among younger women. Taking advantage of the open-minded interest of youth, the department is now making a definite approach to college students of biology and other natural sciences, with the purpose of creating a more wholesome attitude toward the problem in those people who, because of their background are capable of grasping the significance of cancer research, and who are potentially leaders in their individual communities.

It was realized at once that if the incidence of cancer in Massachusetts were to be lessened it was of major importance that individuals showing early or suspicious signs of cancer be brought under medical observation much

earlier than had been the case in the past. Surgeons everywhere were bemoaning the fact that patients were coming to them far too late for hope of permanent relief, yet in many forms of the disease the same surgeons tell us that a large proportion of the cases are curable if proper treatment is applied in the early stages.

Warmth of Speech and Cold Type—A correspondent has sent us a copy of a press release issued by a public health agency. At top is "Press Service," to which our correspondent has added "The World's Worst."

The entire release reads much like a verbatim report of a talk built of rather showy, but unsubstantial words and phrases, loosely thrown together without aid of a good editorial blue pencil, even to secure accepted English grammar. Personality often helps a speaker to get by with careless grammar and slipshod thinking. Before you decide to turn a pleasant sounding speech into reading matter, listen to the sentences, *as* sentences. Note the percentage of facts or ideas per 5 minutes of talking time. Note especially whether loose ends of ideas are left hanging because the speaker intended to come back and fit them neatly into a larger idea later, but forgets to do it as new words intrigue him.

"Damaged Lives": A New Motion Picture—The new picture was introduced to public health workers during the A.P.H.A. meeting at Indianapolis. Says *Journal of Social Hygiene* (Oct., 1933):

After careful consideration, and study of opinions received from several hundred physicians, health and governmental officials, social workers, nurses, and representatives of religious, educational, and other organizations, the Executive Committee of the American Social Hygiene Association has agreed to endorse the motion picture drama "Damaged Lives" recently produced by Weldon Pictures Corporation and dealing with the subject of syphilis. The film, with a supplementary medical lecture film, is expected to be shown in selected representative theatres throughout the United States, the premier showing being at the Majestic Theatre in Boston, on September 15, with the coöperation of the Massachusetts Society for Social Hygiene, the Massachusetts State Department of Health, and other state and city agencies.

This represents the first union of forces between recognized health agencies and commercial producers in the United States in an attempt to combine the technic of sound motion picture photography with authoritative health information for showings in commercial motion picture theatres for paid admissions. In the opinion of competent medical and educational authorities, this union will have far-reaching and important results in adult mass education.

The production is the culmination of 5 years of study by motion picture producers, in coöperation particularly with the Canadian Social Hygiene Council and with the American Social Hygiene Association, regarding preparation of a modern talking picture drama which

might be a worthy successor to Brieux's "Damaged Goods," produced 20 years ago on stage and screen, and the Association's silent drama film, "The End of the Road," which was shown throughout the United States shortly after the World War in connection with the Government's campaign against venereal diseases. Competent critics of all three productions consider "Damaged Lives" by far the most potentially effective in its educational possibilities. It is an appealing human story, produced with extraordinary good taste, is well cast, well acted and well photographed.

The first public showing in the United States, held in Boston, was presided over by the State Commissioner of Health, with speakers representing the Boston Health Department, the dramatic editors of the city, and other groups. There was a distinguished group of patrons and patronesses. It would seem that other cities might make a significant event of the local showing of the picture. See *Journal of Social Hygiene* for additional information, and address inquiries to American Social Hygiene Association, 450-7th Ave., New York.

Where to Find It—The difficulties in tracing health education activities are illustrated by one of the best annual reports. "Educational work" was found under "Maternity, infancy and child hygiene division." It was supplemented by 2 of the 7 sub-headings in the text. There was no tie-up between health education and "Nutrition service," another main heading. "Public health education division" carried 11 sub-topics. Other references: "Radio health talks"; "public meetings" and "radio health talks" under "Sanitation division"; "educational activities," "lectures," and "literature distributed" under "Social hygiene division"; and "educational activities" under "Tuberculosis division."

Could we have all of the above references recognized under "public health education" supplemented by a

cross reference under "health education, public"?

Likewise could there be an index clue to such specialties as "research," "surveys," "statistics," etc.?

The most elaborately indexed of all health organization annual reports contains no references to popular health education. One finds it as "films," "literature," etc., sub-titles under a variety of headings. The illustrations of health education activities usually included are not indexed at all.

The more adequate the indexing the more widely usable and useful will be reports of our own and other cities and states.

Invitations and Reminders—may at times be varied by some simple, inexpensive "dressing up."

Of course there are times when novelty especially if it gives a light touch to your facts or your announcement is inappropriate but there is a wide range of usefulness for non-solemn communications.

A memorandum issued by Social Work Publicity Council, 130 East 22d St., New York, tells how novelty papers may be used for inexpensively "dressing up" mimeographed or multi-graphed announcements and how attention-getting covers may be added to very modest invitations and other simple forms. Send 10 cents for a copy. Several samples of materials are attached to the memorandum.

Dear Editor: Would It Be Worth While?—We have urged that more use be made of good copy which has appeared in various health periodicals. Much that has been written for a single city or state, or a specialized national group, should have a wider audience.

Could we double the size of this department in the *Journal* we would like to fill the added space with sample quotations from journals and house organs, radio talks, news releases and printed matter.

Executives and editors who see many health periodicals may not realize how limited is the range of professional periodical reading by the rank and file. And the health reading of the general public is far more limited.

The subject of *method* in popular health education and publicity receives little attention in national, state and local health periodicals. Among national health journals only in the nursing field is much attention given to methods and materials for promotion and interpretation, except for the materials and projects of the national agencies.

True, more than 5,000 health workers have the opportunity of reading this department of "Education and Publicity" material in the *Journal*. But even that circulation does not cover all staff members of health agencies. Nor does it touch many of the board and committee members and other volunteers, nor the leaders in the countless organizations of men, women, and young people which carry some of the health education job.

Hence and therefore, dear editor, will you consider if you could quote from this department? In some cases you could quote what we have quoted, giving such credit to the original producers as may be fair and desirable. In some other cases you would give credit to the *Journal* and, if possible, to the Education and Publicity department. Try it tentatively?

A lot of material which already has appeared from month to month may be quite usable at the present time.

BOOKS AND REPORTS

Practical Medical Dictionary—
*Thomas Lathrop Stedman, A.M.,
D. (12th ed.) Baltimore: Wil-
Wood, 1933. 1256 pp. Price,
\$7.00, Thumb Indexed, \$7.50.*

The 12th revised edition of this Dictionary which has had an established place with the profession since its first issue in 1908. The present work has had about 1,000 new words added to it and several hundred new sub-titles. It includes also all the changes in the British Pharmacopoeia of 1932. This increase in words has necessitated the addition of 33 pages.

It is manifestly impossible to read every word in a dictionary. One is reminded of the young man who was reading a dictionary, and when asked how he liked it, said he found it "very interesting though it changed the subject too often." By looking for a number of new and test words we arrive at the conclusion that the dictionary is very complete and up to date. An appendix gives a table of drugs, their doses, and uses; weights and measures; comparative temperature and barometer scales, and a list of the microparasites pathogenics for man and some animals. The printing and illustrations are of the high quality for which this publication has been noted. One can feel no hesitation in recommending it thoroughly to the profession. MAZYCK P. RAVENEL

Fetal, Newborn, and Maternal Morbidity and Mortality—White House Conference. New York: Appleton-Century, 1933. 486 pp. Price, \$3.00.

The subject matter of this conference report is divided into two parts. The first is a summary of the findings and includes a set of recommendations

and a bibliography. The second and larger part is devoted to a discussion of the various elements entering into fetal, newborn and maternal morbidity and mortality. It is in the form of a series of monographs with numerous reading references and on this section the summary and recommendations are based.

Inasmuch as the recommendations seem to include about all that present-day knowledge of the subject authorizes, they are given in full.

1. Efforts must be increased to provide better prenatal care for more women. In general, only early diagnosis allows adequate treatment of a disease which complicates pregnancy and is likely to harm mother or baby.

2. A warning should be disseminated that compliance with the insistent demand made by women for shorter and more comfortable labors inevitably implies risks both for mother and baby.

3. Interference with pregnancy or labor should be limited to well defined indications.

4. In view of the fact that abortions are responsible for a large part of maternal mortality and, particularly, for later maternal morbidity, all febrile cases of abortion should be hospitalized.

5. Appropriate changes should be made in official birth and death certificates so that more and more precise information can be obtained concerning the actual causes of death of either mother or infant in connection with pregnancy and birth.

It will be seen that nothing especially new has come of this study, but what is known has been worked into shape for easy reference.

MERRILL E. CHAMPION

**Our Movie Made Children—By
Henry James Forman. New York:
Macmillan, 1933. 284 pp. Price,
\$2.50.**

This book is a summary of the results of a 4-year nation-wide study by a group

of skilled investigators. In it we have a collection of facts secured in schools, colleges, children's homes, courts, and institutions of various kinds.

A popular opinion that most of the movie details go over the children's heads is thoroughly disproved by tests with 3,000 persons. "The amount that average children carry away is astonishing" and, strange as it may seem, they actually recall more of a picture at the end of a week than on the day after it was seen.

Emotional excitement has been carefully measured and found to be very great with most children. This is because they see the scene as actual life whereas adults can reason "it's only a picture." Since this emotion can be relieved only slightly in a theatre by physical action, it is especially dangerous.

Children's sleep is adversely affected by movies. This has been demonstrated with the "hypnograph"—a delicate instrument for recording restlessness. Either the sleep is more fitful than normal or it is in the nature of a drugged stupor, similar to that caused by extreme fatigue. Exciting pictures often show these effects on sleep for several days.

Easy money, fine clothes, luxury, wild parties, sex suggestions, exert an insidious appeal. Young people report the movies a liberal education in love-making with the sex side often overemphasized. "The road to delinquency is heavily dotted with movie addicts and it needs no crusaders, or preachers, or reformers to come to this conclusion."

Everyone interested in the physical, mental, or moral welfare of children should read this book and take a positive stand against the evils that are exposed. Parents should consider carefully the seriousness of the facts and supervise the movie-going habits of the children as far as possible.

JOHN HALL

A Short History of Dentistry—By Lillian Lindsay. London: John Bale, Sons and Danielsson, 1933. 88 pp. Price, \$1.25.

With the increasing interest in dentistry as an aid to public health this little book is timely. Short as it is, it gives an excellent survey of the evolution of the science and art of dentistry. The many studies in various parts of the world, as to the effect of various foods on the development of the teeth and their health is another reason which makes this book valuable. Few advances were made until about a century ago but dentistry now occupies a safe place in the scheme of public health. We recommend this little book to all who are interested in this fascinating subject. MAZYCK P. RAVENEL

I Go Nursing—By Corinne Johnson Kern. New York: Dutton, 1933. 256 pp. Price, \$2.50.

Nurses are often accused of being too inarticulate about the many human interest experiences they have in the round of their duties. Here is a nurse who has loosened up and given us a peep at life as she saw it and lived it while a pupil nurse in a large hospital nursing school, and later as a private duty nurse, the locale of whose activities ranges from San Francisco and its environs to a lumber camp on the Canadian Border and a cottage in the Canadian Rockies.

The nurse shows a keen insight into the psychology of her patients and unusual powers of observation. She gives the impression of being slightly "hard boiled" and cynical, yet she knows how to appeal to the reader's emotions. The book is decidedly interesting.

The experiences here depicted fall in line with what most people, who do not know much about nursing, traditionally think every graduate nurse meets; but most modern nurses will be indignant at the impression this book is apt to

give, that all nursing school supervisors are only professional snoopers and deserve only secret disrespect; that a nurse cannot get through some of the harrowing experiences of night duty without dopping herself on bromides or black coffee; and that a nurse can watch a patient die in a large hospital and, apparently without having a physician see him, prepare him for the morgue and, with another nurse, deposit him in the morgue.

EVA F. MACDOUGALL

The Road to Health—Book I and Book II—By Herman M. Bundesen, M.D., and Corrine Manry. San Antonio: Laidlow Bros., 1932. Price, Book I, \$.52 and Book II, \$.56.

The First Book gives a clear view of the fundamental health activities which should be carried out in the daily life of every child—the first need in child training. The different activities are emphasized in story form with colored illustrations.

The authors have written this Second Book to follow up the First Book, stressing the fundamental health activities which should be carried on daily. Lists of questions are given throughout which could be nicely correlated with the morning health review.

The illustrations are very well done and make the book interesting to the child of this age group. These books should prove valuable allies in carrying out a health-education program.

BESS EXTON

Report on General Survey of the Problems of Sewage Treatment and Disposal in Willamette River Valley, Oregon—State of Oregon, Reconstruction Advisory Board.

State-wide demand for abatement of stream pollution in the Willamette River Valley brought about the appointment of a consulting board by the Governor of Oregon, which studied the existing conditions, assembled data on

sewage disposal at the Willamette Valley cities and on the financial status of those cities, then pointed out definitely what improvements were needed in the 40 or more towns, cities or localities to bring about cleaner conditions in the Willamette River. The report is available at the office of the Reconstruction Advisory Board, Spalding Building, Portland, Ore.

ARTHUR P. MILLER

Safety First for Little Folks—By Lillian M. Waldo. New York: Scribner, 1933. 165 pp. Price, \$.64.

That safety education has definitely established its place in the elementary schools is proved by statistics which show a steady increase in fatalities for adults and for children of preschool age, and a marked decrease for children of school age.

The story centers around a little girl who dreamed that she took a trip to Danger Land and who tells of her experiences with the crippled children she met there. The safety lessons drawn are correlated with civic instruction to show children what the community is doing for their welfare and how they can cooperate. The book contains a number of illustrations.

A very good book for children of the third, fourth, and fifth grades if studied under the supervision of an understanding teacher.

BESS EXTON

Frontiers of Medicine—By Morris Fishbein, M.D. Baltimore: Williams & Wilkins, 1933. 207 pp. Price, \$1.00.

Modern medicine is so significant to the layman that the story of its progress from earliest times to the present should be as fascinating to him as to its own practitioners. In this little book, one of the Century of Progress Series, medicine's chief impresario has told the story concisely and well. About half of the book is devoted to medical history prior

to the glorious days of Pasteur, the chemist who founded the modern science of medicine, while the remainder is concerned with the present aspects of this profession, both as an art and a science. Preventive medicine is described in various chapters, although somewhat sketchily, due mainly to the limitations of space. The book is well printed but has no index. It should prove of interest to anyone who desires a succinct history of the development of medical science in all its branches, and will serve to inspire the reader with an appreciation of the scope and beneficence of this most important art.

JAMES A. TOBEY

Public Health Nursing in Industry
—By Violet H. Hodgson. New York: Macmillan, 1933. 249 pp. Price, \$1.75.

Industrial nursing has been the least clearly defined of all the phases of public health nursing. Because it has been under individual industry control, the administrative set-ups have been various, and the methods, procedures and programs have been very diverse, as have been the qualifications of the nurses employed. Books have been written about school nursing, visiting nursing, and tuberculosis nursing; but except for Florence S. Wright's brief monograph written 12 years ago, Mrs. Hodgson's book is the only one in the field of industrial nursing.

Plant managers and industrial physicians as well as industrial nurses will welcome Mrs. Hodgson's book in which for the first time is brought together the current practices of industrial nursing, and the definite objectives and principles of this service. The relationship of the nurse to the physician, the plant managers, the employees, and the community agencies is definitely defined. Suggestions are given for various types of set-up, both inside and out of the factory, including plans for affiliation

with community public health nursing agencies. Standing orders, lists of equipment, records, methods, and procedures are outlined in detail. In fact, this book is to industrial nursing what the *Manual of Public Health Nursing* is to public health nursing in general, and should be available for all plant managers, industrial physicians, and nurses.

This book should be the starting point for further contributions in this field, contributions which will detail the various plans which are based on the fundamental principles of industrial nursing so ably given by Mrs. Hodgson.

VIRGINIA A. JONES

To Be or Not to Be, A Study of Suicide—By Louis I. Dublin, Ph.D. and Bessie Bunzel. New York: Harrison Smith and Robert Haas, 1933. 443 pp. Price, \$3.50.

Statistical study of suicide discloses some interesting facts which lead to a speculation as to causes in this complex problem. As a background for the study proper, the changing ideas of various groups and civilizations in connection with the act of suicide are presented. The author is well aware of the complexity of the problem, since it is bound up with the habits, customs, and standards of life of individuals and communities as well as with the value which these attach to life. He has carefully studied not only the records of the Metropolitan Life Insurance Company, of which he is statistician, but also official records here and abroad, and bases his analyses on data so obtained.

In the majority of countries studied suicide rates were higher during the years 1926 to 1930 than during the pre-war years 1910 to 1914, and a distinct upward trend was noted during the post-war period. Although the American negro is much less apt to commit suicide than the white, nevertheless other colored peoples show high rates, so that

suicide is not held to be primarily a racial trait. Analysis of suicides among urban and rural peoples shows a much higher frequency among the former. American data harmonize with a British study which indicates that suicide predominates at both ends of the social scale, although chiefly at the upper end.

The low suicide rate in Roman Catholic countries is thought to be related to the authority of the church in which members accept guiding precepts without question, and the church forms the background of communal life. Protestant suicide rates are distinctly higher than Catholic, but by far the greatest recent increase is among the Jewish population. The latter fact is startling since the Jews in pre-war times showed a low rate.

Other interesting chapters deal with such topics as a survey of the historical background, a discussion of law and life insurance, of the psychology of

suicide, and of the prevention of suicide. In the last chapter is a very interesting discussion on the development of the "well-adjusted adult"—the problem facing the psychiatrist, the layman, the parent, the church, the school, etc. The claim of the "necessity for evolving a sound philosophy of life" is one most of the readers will agree to.

Statistical data together with a bibliography are appended. The book throughout is most intensely interesting, shows a vast amount of research and study and careful deductions from the facts obtained. Suicide is a matter of the utmost importance from many different angles, and in this book we have a study which is enlightening and sound. It can be recommended to many types of readers, especially those who are in professions concerned in the social, religious, mental and medical aspects of life. E. W. STEARN

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Nutrition Propagandists Take Note—Research that throws some doubt on the marked anti-infective virtues of vitamin A is recounted here. The conclusion seems to be that under ordinary circumstances sufficient quantities of vitamin A are found in the usual diets recommended for children, and that a larger intake of vitamin A or carotene may be undesirable.

CLAUSEN, S. W. Limits of the Anti-Infective Value of Pro-Vitamin A (Carotene). J.A.M.A. 101, 18:1384 (Oct. 28), 1933.

Another Survey of Colds—Over a 3-year period, 3,000 persons reported an average of 2 cases of respiratory disease per year, half of which were head colds only. Another group of students reported 3 colds per year, three-quarters of which were head colds only. Sex differences were not significant but age and seasonal differences were.

COLLINS, S. D. and GOVER, M. Incidence and Clinical Symptoms of Minor Respiratory Attacks With Reference to Variation With Age, Sex and Season. Pub. Health Rep. 48, 38:1155 (Sept. 22), 1933.

Bacteriological Successes and Failures—We Americans are reticent about one thing—our mistakes. This paper by a British bacteriologist dwells as much upon the "boners" made by research workers as upon the glories of their successes. More of this honesty would make us a little more humble and a lot more understanding.

FLEMING, A. The Trend of Modern Research in Bacteriology. J. State Med. 41, 10:559 (Oct.), 1933.

All About Diphtheria Prophylaxis—Clear and concise, this straightforward statement of the principles of diphtheria immunization and treatment

should be on the tip of the tongue of every health worker to be passed on intact to uninformed or doubting lay persons.

HARRISON, W. T. Immunization Against Diphtheria. Am. J. Nurs. 33, 10:923 (Oct.), 1933.

Measures of Health Administration—The story of how municipal health department measuring grew introduces the uses of the *Appraisal Form* to sanitarians who may not be readers of our own *Journal*.

HISCOCK, I. V. Principles of Appraising Municipal Health Practice. Municipal Sanitation 4, 10:337 (Oct.), 1933.

Of Interest to Pediatricians—Cod liver oil has little if any value in promoting blood regeneration in anemia. This scientific candor emanates from one of the important oil producer's laboratories. At least, let us give the devil his due.

HOLMES, A. D., et al. The Value of Cod Liver Oil in the Treatment of Anemia. New Eng. J. Med. 209, 17:839 (Oct. 26), 1933.

New Resuscitation Method—An ingeniously devised rocking stretcher for the resuscitation of victims of suffocation is described. Its advantages over the Schafer prone pressure method are that greater air exchange in the lungs is effected, its operation requires less effort, and the victim can be kept warm more easily.

KILLICK, E. M. and EVE, F. C. Physiological Investigation of Rocking Method of Artificial Respiration. Lancet 225, 5744:740 (Sept. 30), 1933.

Why Mothers Die—Surveying 285 maternal deaths in New York State, the author of this preliminary report concludes that over half may be ascribed

to faulty management, one-sixth to negligence of patient, leaving about a third in the non-preventable class.

KOSMAK, G. W. A Study of the Maternal Mortality of New York State. New York State J. Med. 33, 19:1143 (Oct. 1), 1933.

How to Teach Health to Children

—Some of the advantages of the unit method of teaching health are that students become interested in solving specific health problems, and these problems have to do with living here and now. A practical example of the method is the author's "A Suggested Teaching Unit for Secondary Schools on Tuberculosis and Its Prevention," issued by the Massachusetts Tuberculosis League.

LATIMER, J. V. Unit Teaching in Health Education. J. Health & Physical Ed. 4, 8:10 (Oct.), 1933.

Vitamin D and Dental Caries—

Studying the dietary factors in the control of dental caries, the author concludes that ordinary diets are more deficient in vitamin D than in the other vitamins, and that irradiation apparently was a more potent protection against this lack than the administration of viosterol.

MCBEATH, E. C. Nutritional Control of Dental Caries. New York State J. Med. 33, 18:1086 (Sept. 15), 1933.

Venereal Disease Follow-up—

Recommendations for an effective city-wide social service for venereal cases, based upon a painstaking survey of the situation in one city (Boston), are no doubt applicable to most other cities in the United States.

MORRIS, E. H. Clinic and Field Agency Relationships in Syphilis and Gonorrhea Clinics. New Eng. J. Med. 209, 15:735 (Oct. 12), 1933.

Betel-nut Chewing Exonerated—

Betel chewing is always listed among the exciting causes of cancer in the East. But it appears that betel is

chewed throughout India whereas the cancer area is localized in the tip of the Indian peninsula. This observer believes the exciting causes are not betel but the practice of holding a quid of shell lime and particularly vile tobacco in the mouth over long periods of time.

ORR, I. M. Oral Cancer in Betel-Nut Chewers in Travancore. Lancet 225, 5741: 575 (Sept. 9), 1933.

Growth in Times of Stress—

In Hagerstown, a typical small urban community, the average of the weights of children was not substantially different in 1933 than in the predepression years 1921 and 1927. From the facts presented it is concluded that in this community those most in need of aid are getting sufficient food to maintain a reasonable standard of nutrition.

PALMER, C. E. Growth and the Economic Depression. Pub. Health Rep. 48, 42:1277 (Oct. 20), 1933.

What Poverty May Be Doing for

Illness—Morbidity statistics, that we hope will forever put a damper upon the "what a healthy country we are" propagandists who have been so vocal since the business depression began, are provisionally presented in this preliminary report of a tremendously significant illness survey.

PERROTT, G. ST. J., *et al.* Sickness and the Economic Depression. Pub. Health. Rep. 48, 41:1251 (Oct. 13), 1933.

Chemistry of Nutrition—Excellent

as a background for reading or discussion is this review of the scientific research leading to our present knowledge of nutrition. An invaluable panacea for vitaminophobia, mineralorrhea or milkitis.

SHERMAN, H. C. A Century of Progress in the Chemistry of Nutrition. Sci. Month. Nov., 1933, p. 442.

Contributions to Tuberculosis Case-Finding—Three allied papers on tuberculosis report upon Massachusetts

studies. One warns against waiting for symptoms in school children; the second points to pitfalls in X-ray interpretation; and the last to the improvements in the technic of treatment urging more widespread use of collapse therapy.

POPE, A. S., *et al.* Pulmonary Tuberculosis in Adolescents With Special Reference to Frequency, Diagnosis and Prognosis, etc. *New Eng. J. Med.* 209. 16:765 (Oct. 19), 1933.

Protecting Workers From Radio-Active Paint—Painting watch and clock dials with radio-active paint may be made safe if putting the brush in the mouth is prohibited, the material adequately protected, the factory kept really clean and well ventilated, and only cleanly workers employed. Specific directions are given.

SCHWARTZ, L., *et al.* Health Aspects of Radium Dial Painting. *J. Indust. Hyg.* 15, 5:362 (Sept.), 1933.

Newer Knowledge of Pneumonia

—In this series of three papers there are presented: the prevalence of specific strains of pneumococci in contacts as contrasted with the general population; the taking of specific treatment measures to rural communities and the success achieved thereby; and the latest information on types and typing. We would do well to study all three papers.

SMILLIE, W. G., *et al.* The Epidemiology of Lobar Pneumonia, etc. *J.A.M.A.* 101, 17:1281 (Oct. 21), 1933.

Effects of Ionized Air—Should you fall under the spell of an "air ionizer," remember this conclusion: "under the conditions of the present experiments nothing definite was found to justify the use of artificial ionization in general ventilation." More extensive and critical experiments are under way.

YAGLOU, C. P., *et al.* Observation on a Group of Subjects Before, During and After Exposure to Ionized Air. *J. Indust. Hyg.* 15, 5:341 (Sept.), 1933.

NEWS FROM THE FIELD

THEOBALD SMITH GETS ROYAL SOCIETY PRIZE

THEOBALD SMITH, pathologist, of Princeton, N. J., was announced as the winner of the Copley Medal, awarded by the Royal Society, Great Britain's oldest scientific organization.

Dr. Smith was honored for his original research and scientific observations on the diseases of animals and men. He is 74 years old.

The London award tops a list of scientific honors bestowed upon Dr. Smith during a long scientific career. He received the Sedgwick Memorial Medal of the A.P.H.A. in 1930.

He was formerly in charge of pathological work with the U. S. Department of Agriculture. He was

Professor of Comparative Pathology at Harvard University from 1896 to 1915.

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

THE Association of Women in Public Health met at the Claypool Hotel in Indianapolis, Ind., October 8 and 9, as an affiliated organization of the American Public Health Association. A short business session was also held after the annual dinner and the following officers were elected:

President—Dr. Ada E. Schweitzer, formerly Director of the Child Hygiene Division of the Indiana State Board of Health

Vice-President—Dr. Ellen S. Stadtmuller, State Director of Child Hygiene, California

Secretary—Pauline Brooks Williamson,

Chief, School Health Bureau, Welfare Division, Metropolitan Life Insurance Company, New York, N. Y.

Treasurer—Dr. Grace Wightman, Chief of Child Welfare Bureau, State Department of Health, Springfield, Ill.

The following women were asked to serve on standing committees: Dr. Mary R. Lakeman, Boston; Dr. Clara E. Hayes, New York; Sally Lucas Jean, New York; and Mrs. Walter McNabb Miller, New York.

The Health-Know-Meter, which was prepared for the International Congress of Women held in Chicago in July was featured as a part of the Educational exhibit at the American Public Health Association meeting.

CHEMICAL LITERATURE TO BE COÖRDINATED

THE International Office of Chemistry has recently been created with headquarters in Paris with the following purposes: to render accessible to interested persons the existing literature of chemistry, to facilitate the registering, filing and diffusion of the literature now in course of production, and to insure coördination between documentation in chemistry and that of other fields of scientific knowledge. The address of the new organization is 49, Rue des Mathurins, Paris 8.

STUDY OF TYPHUS IN ALABAMA

A CAMPAIGN for the eradication of typhus is being launched in ten or twelve counties of southeastern Alabama, it is stated. The U. S. Public Health Service, with headquarters at Dothan, is conducting a study to determine the best methods of prevention and control of the disease. Dr. Adolph S. Rumreich is assembling the data.

ROCKEFELLER FELLOWSHIPS

THE Rockefeller Foundation has granted fellowships for a year's study at either Harvard or Johns Hop-

kins University medical schools to the following full-time county health officers:

Dr. Norris C. Knight, Sunflower County, Miss.—Member A.P.H.A.

Dr. Cecil J. Vaughn, Holmes County, Miss.—Member A.P.H.A.

Dr. Alton R. Perry, Washington County, Miss.

Dr. Millard C. Hanson, member A.P.H.A., of Mansfield, Ohio.

MALARIA LIBRARY

A MALARIA library was founded in Rome by the Stazione Sperimentale per la Lotta Antimalarica in 1925, and an *Index to Malaria Literature* is issued annually by the Station.

To make this as complete a central malaria library as possible they appeal to all malariologists to send books, reports and articles on malaria.

Photostat copies of any articles in the library can be had, on request, at cost production.

All publications and requests should be addressed to "The Director, Stazione Sperimentale per la Lotta Antimalarica, Corso Vittorio Emanuele 168, Rome (16)."

CHILD LABOR DAY

FOLLOWING its custom of nearly thirty years, the National Child Labor Committee has designated the week-end of January 27-29 as the period for the observance of Child Labor Day.

It is estimated that the industrial codes have released 100,000 children under 16 years from industry. Another 30,000 boys and girls 16 to 18 years have been removed from especially hazardous work. On the other hand there are still approximately 240,000 children under 16 years working in occupations not covered by codes. These children are employed largely in industrialized agriculture, such as the production of sugar beets, cotton,

tobacco, and truck farm products, in street trades, especially newspaper selling, and in domestic service. The National Child Labor Committee, 419 Fourth Avenue, New York, N. Y.

PERSONALS

DR. LEROY A. WILKES, formerly of the American Child Health Association of New York, is now Executive Secretary of the Medical Society of New Jersey, with offices in Trenton.

DR. EUGENE C. PECK, member A.P.H.A., has been appointed Health Officer of Garrett County, Md., and also Deputy State Health Officer. Dr. Peck was formerly Assistant Health Officer of Newton, Mass.

DR. HENRY D. CHADWICK, member A.P.H.A., recently resigned as controller of tuberculosis of Michigan to become Commissioner of Public Health of Massachusetts, at Boston.

ROSS L. GAULD, M.D., of Jonesboro, Tenn., member A.P.H.A., has been appointed Health Officer of Maury County, Tenn., to succeed Hainan C. Bushy, M.D., member A.P.H.A.

EDWIN T. RAMSEY, M.D., of Clark, S. Dak., member A.P.H.A., was elected President of the South Dakota Health Officers' Association at the annual meeting in Huron in October.

JAMES GEORGE MCALPINE, Ph.D., of the U. S. Public Health Service, member A.P.H.A., has been appointed Director of Laboratories of the Alabama State Department of Health to succeed the late Dr. Leon C. Havens.

DR. MORLEY B. BECKETT, formerly Health Officer of Isabella County, Mich., member A.P.H.A., has been appointed county field agent for the Michigan State Department of Health, largely for the study of the full-time county and district health departments.

DR. FREDERICK J. SWIFT, member A.P.H.A., has assumed his duties as

Deputy Health Commissioner of Iowa, with offices at Des Moines. He succeeds Dr. William W. Johnston, F.A.P.H.A.

CONFERENCES

February 5-9, 1934, Third International Heating and Ventilating Exposition, Grand Central Palace, New York, N. Y.

Spring, 1934, Statistical Conference, International Statistical Institute, London, England.
